Valerie Greg International Student Fund

The Board of the Digital Government Society inaugurated the Valerie Gregg International Student Fund (the Fund) to honor Valerie Gregg's commitment to building a sustainable digital government research community. As an NSF program manager for digital government, Valerie worked tirelessly to build bridges across disciplines, professions, and cultures. The Fund, seeded with a bequest from her estate, is dedicated to Valerie's special interest in supporting doctoral students as they embark on their research careers. To continue her legacy and honor her dedication, the DGS is seeking personal and institutional contributions to the Fund on an ongoing basis for the purpose of funding the participation of doctoral students in the Doctoral Colloquium at the International Conference on Digital Government Research.

To contribute to the Fund, please contact Mila Gasco-Hernandez mgasco@albany.edu, Treasurer of the Digital Government Society.

Digital Government Society President Welcome Letter

Dear Digital Government Society Members, distinguished guests, and participants,

It is my great honor to welcome you to our annual International Digital Government Research Conference. For 26 years now, DG.O has been a meaningful platform where our members meet and advance digital government research in a collaborative way. Together, we share groundbreaking ideas, dive into insightful debates, and build long lasting networks and communities. We are thrilled to announce that this year, following the pattern of Poland and Taiwan conferences in the last two years, DG.O has attracted a historical number of submissions and participations. We received around 210 registrations from 32 countries in different parts of the world. You all are part of the history of this exciting community that has been and will continue to shape the development of research on the future of governance and society.

Last year, when I said that we were facing an unprecedented complexity in our world. I did not anticipate how rapidly the complexity could grow, evolve and shift. We always say that technology is a double-edged sword, but never before, it showed us just how alarmingly, technology can move the dial and play such critical role in both providing solutions and exacerbating the nature of many problems facing the public sector and our society. To name a few, climate modeling and monitoring, renewable energy tech, global health data sharing, pandemic monitoring and prediction, digital identity, vaccine/treatment development and distribution brings new hopes and solutions. Yet, cyber warfare and cybersecurity, misinformation and disinformation, Al surveillance and loss of privacy, automation and job displacement, and digital exclusion introduces yet a whole set of wicked problems and instability to our collective future.

To address these opportunities and pressing issues, researchers and practitioners must work together to create global standards, governance structures, and collaboration frameworks that can maximize technology's benefits while minimizing its risks.

The Digital Government Research Conference (DG.O) in Porto Alegre, Brazil is significant not only because it brings together leading scholars and professionals but also because it provides a platform for discussions that can shape the future of public governance worldwide. For Brazil and Latin America, it represents an opportunity to lead the digital governance conversation and create solutions that can improve transparency, service delivery, inclusion and equality in the society. The discussion taken place in this conference can have lasting and global implications for digital government research and practices.

Here, I wish to express my deepest gratitude to the host and conference organizing teams. So much planning and execution efforts have been done to make this conference a productive venue. The conference chairs, program chairs, poster chairs, doctoral colloquium chairs, and program committee has, once again, excelled in bringing in a variety of thought stimulating topics and speakers. I would especially like to highlight the contribution of Edimara Luciano, who has been extremely persistent, and hardworking in leading the organizing team. Our gratitude goes to the Program Chairs Flavia Bernardini, Marie Anne Macadar, David Dueñas-Cid, and Jooho Lee for all your dedication and work, and for creating the inspiring conference program.

Sincerely thanks to all the track chairs who reached out to the potential contributors and managed the review in a short period of time, and reviewers for responding in such prompt fashion. **Also, thanks go to all the staff and the student volunteers for managing all the sessions. Finally, I would like to thank all our sponsors for their support of the different awards and activities of the conference.**

Jing Zhang, Clark University, USA
President of the Digital Government Society

Conference Chairs Welcome Letter

It is our great pleasure to present the proceedings of the 26th Annual International Conference on Digital Government Research (DG.O 2025), held in Porto Alegre, the capital of Rio Grande do Sul, Brazil, from June 9 to 12, 2025. This edition was a landmark for the community: not only the 26th in a long and successful series, but also the very first time the conference took place in South America. The occasion brought together colleagues from 32 countries across different world regions, making DG.O 2025 a truly global gathering and one of the largest in the history of the conference.

The conference was hosted on the beautiful campus of the Pontifical Catholic University of Rio Grande do Sul (PUCRS), which provided excellent facilities and a vibrant setting for academic exchange. Beyond the university, the event was immersed in the welcoming culture of southern Brazil and the broader Brazilian context — a country marked by rich traditions, diversity, and hospitality. This atmosphere contributed to an inspiring environment for dialogue, reflection, and collaboration, fully in line with the ethos of the DG.O community.

Organized under the auspices of the Digital Government Society (DGS), DG.O 2025 welcomed around two hundred participants. This proceedings shows the complete versions of the 119 papers presented over the course of four days, across 24 thematic tracks, chaired by 63 colleagues. Many served in multiple roles, reflecting the dedication and collaborative spirit that characterize our community. Together, these efforts ensured both the scientific quality and the intellectual diversity of the program.

The theme of DG.O 2025, Digital Government Fostering Social Cohesion for Reducing Inequalities, was particularly meaningful in the Brazilian context and resonated strongly with broader global debates. Digital government goes far beyond technology: it holds the potential to address persistent social and economic disparities. Social cohesion is both a challenge and an aspiration in societies marked by inequality, and the Brazilian and Latin American contexts underscore the importance of inclusive initiatives that promote belonging, engagement, trust, and resilience.

The diversity of the program reflected this theme in multiple ways. Tracks and sessions explored, among others, artificial intelligence and ethics in government, data-driven governance and open data, digital transformation strategies, cybersecurity and responsible innovation, digital democracy and GovTech platforms, smart cities, and citizen engagement. These contributions showcased a wide range of methodologies — from computational modeling to in-depth case studies, qualitative approaches, participatory design, and mixed methods — underscoring the intellectual richness of the field.

The value of DG.O 2025 was not only academic but also cultural and geographic. Just as digital government research addresses questions of inclusion, participation, and shared value, the conference itself embodied these principles by bringing together scholars and practitioners from diverse regions, traditions, and perspectives. Hosting DG.O in Brazil, a country with extraordinary social, cultural, and ethnic diversity, reinforced the importance of connecting academic studies with real-world challenges in societies where inequalities are acute but opportunities for innovation and collaboration are equally significant.

Organizing DG.O 2025 was a collective effort made possible by the energy, generosity, and commitment of many individuals and institutions. We are deeply grateful to the authors, reviewers, track chairs, and program committee members, whose contributions ensured the quality of these proceedings. We thank the keynote speakers, panelists, PhD students attending the Ph.D. Colloquium, poster, and workshops participants, and paper sessions attendees, whose engagement enriched the debates and fostered new opportunities for collaboration.

We expect that the papers collected in these proceedings will not only document the contributions of DG.O 2025 but also inspire further inquiry and collaboration. May they provide fruitful reading and generate insights that advance research and create impact in practice, contributing to our shared endeavor of fostering digital government that promotes social cohesion and reduces inequalities worldwide.

Edimara M. Luciano, Pontifical Catholic University of Rio Grande do Sul, Brazil

DG.O 2025 Conference Chairs

Program Chairs Welcome Letter

Dear Colleagues,

Welcome to the 26th Annual International Conference on Digital Government Research!

This year, our conference theme is "Digital Government Fostering Social Cohesion for Reducing Inequalities". We have received a diverse and high-quality range of submissions, totaling 268 papers. From these submissions, we have accepted 119 papers, 5 panels, 6 workshops, and 28 posters for presentation at the conference.

None of this would have been possible without the dedication of our program committee members. A total of 240 committee members contributed with more than 550 comprehensive reviews to assess the quality of the submissions. The papers were selected through a rigorous and competitive process guided by 74 track chairs of 24 tracks, all of whom worked diligently to ensure a successful conference. We extend our sincere thanks to everyone who has been part of this effort: the organizing committee, program committee members, Ph.D. volunteers, and Digital Government Society members who contributed to managing the conference, including Mila Gasco and Paula Hauser, as well as Loni Hagen for the website support. We also sincerely thank Frederique Belliard, Monique IJzinga, and Rixt Tuinstra from the TU Delft library, who were responsible for publishing the proceedings, Érica Menezes for supporting the work of the Program Chairs, and José Viterbo Filho for all the support in pioneering this new proceedings process.

We are confident that you will find the DG.O 2025 conference to be a source of stimulating content, ideas, discussions, and research avenues that will contribute to your professional development. We are delighted to have played a role in the success of this year's conference and hope it serves as a stepping stone for future endeavors.

Track 1: Application of Artificial Intelligence, Data Science, and Computational Methods for Data-driven governance

Track Description

The aim of the track is to focus on papers discussing the harnessing of computational methods to transform digital government. Its focus includes: a) Technical and behavioral studies using computational approaches to analyze, model, and simulate social phenomena; b) Data-driven decision-making and citizen service enhancement; c) Empirical studies leveraging computational methods and big data to co-create public services; d) Innovative models and tools for improved government service delivery; e) Design science research developing and evaluating technical artifacts; f) Best practices in applying AI and machine learning to government operations. The track chairs also invited authors to submit papers aligned with the conference theme of "digital government fostering social cohesion for reducing inequalities" by applying AI, data science, computational methods, and big data.

Abstract. Government agencies possess large quantities of valuable data, which have to be leveraged to the highest possible extent, using the most advanced processing methods, in order to extract as much as possible the valuable knowledge they contain, in order to support future decisions, policies and programs. In this paper we develop a methodology for sophisticated advanced leveraging of data that government agencies possess concerning firms' behaviour during recessionary economic crises as well as firms' vulnerability to them, which is based on a combination of artificial intelligence (AI) techniques, both unsupervised and supervised ones. Economic crises are one of the most important significant challenges that market-based economies face, which has detrimental effects on businesses of most sectors. Governments employ diverse interventions, including extensive programs in order to mitigate the adverse effects of economic crises, which may include employment reduction, famine, public disturbance, and political instability. These government interventions, particularly the extensive economic stimulus programs during crises, can be rendered more efficacious by concentrating on the firms that are more vulnerable to economic crisis. In this direction the proposed methodology includes initially the use of unsupervised learning AI techniques (clustering) in order to identify based on the abovementioned government data the main typologies of firms with respect to the impacts of economic crisis they experience. Then it includes supervised learning AI techniques (classification) in order to predict based on these data the susceptibility/vulnerability of individual firms to future economic crises. Additionally, the authors present an initial implementation and substantiation (application) of the proposed methodology utilizing a dataset from the Greek Statistical Authority made available upon request, pertaining to 363 companies, data acquired during the Greek economic crises that occurred from 2009 to 2014. Satisfactory results were obtained from this first application.

Keywords. Artificial Intelligence, Government data, Machine Learning, Clustering, Economic Crises

1. Introduction

Government agencies possess large quantities of valuable data, which have to be leveraged to the highest possible extent, using the most advanced processing methods, in order to extract as much as possible the valuable knowledge they contain, in order to supporting future decisions, policies and programs. In this paper we make a

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

contribution towards this direction: we develop a methodology for sophisticated advanced leveraging of data government agencies possess concerning firms' behaviour during recessionary economic crises, as well as firms' vulnerability to them, using a combination of artificial intelligence techniques, both unsupervised and supervised ones. However, the proposed methodology has a wider applicability to a wide range of social and economic problems, for supporting the corresponding government decisions, policies and programs.

Economic crises are one of the most important significant challenges faced by market-based economies; they are caused by various events leading to instability of economic activities, which may cause recessions and result in economic crises of varying durations, geographical scopes, and intensities, (Allen, 2016; Keeley & Love, 2010; Knoop, 2010; Kottika et al., 2020; OECD, 2009a; Saifi & Horowitz, 2023). Economic crises that happened over the span of the previous century are succinctly outlined in (Knoop, 2010), along with their causes and detrimental effects on social and economic scales. In the beginning of the twenty-first century, there was an initial outbreak of the severe Global Financial Crisis in 2007 (Loukis et al., 2021; OECD, 2009a). Subsequently, the COVID-19 pandemic emerged, sparking an additional economic crisis (Baldwin & di Mauro, 2020). Most recently, the Ukraine conflict has led to substantial price increases for commodities including oil, gas, wheat, and others, which has led to another economic crisis. We generally observe that economic crises have become more frequent in this century and tend to propagate to wider geographic areas due to the internationalization of the economy, so periods of "normal" economic activity tend to become shorter, while periods of recessionary economic crisis tend to increase.

The society and the economy are profoundly impacted negatively by these economic crises (Dagoumas & Kitsios, 2014; Das, 2022; Keeley & Love, 2010; OECD, 2009a; Oliveras et al., 2021; Stylidis & Terzidou, 2014). As a consequence of economic crises, which are characterized by a decline in aggregate economic activity and incomes, the majority of firms encounter significant hindrances to their economic standing. These include a reduction in sales, which subsequently affects revenue and liquidity; an escalation in debts; a decrease in investments and personnel employment; and in certain cases, an inability to sustain operations and insolvency. Nevertheless, there is considerable variation in the adverse effects of economic crises among firms (Allen, 2016; Arvanitis & Loukis, 2023; Knoop, 2010; OECD, 2009a); certain firms demonstrate greater capacity to manage such crises and, consequently, are more susceptible/vulnerable to them; conversely, others lack the capability to do so effectively and are thus more susceptible/vulnerable.

These economic crises pose challenges to the governments, such as public disturbance, political instability, poverty and famine, and the governments struggle to minimize all these challenges and their destructive effects on the economy and the society. In order to achieve this objective, governments implement extensive interventions, including massive economic stimulus programs that provide firms with financial aid, tax rebates, subsidies, investment financial support, minor interest rate (or even interest less) loans, and so forth (Coenen et al., 2012; Kalinowski, 2015; Khatiwada, 2009; Taylor, 2018). For optimal efficiency and effectiveness of these interventions, particularly the extensive economic stimulus programs, it is important that they are accurately aimed and prioritized towards the most susceptible/vulnerable firms to the economic crisis.

In order to effectively allocate government support during an economic crisis, it is beneficial on one hand to understand the existing typologies of firms with respect to the impacts of economic crisis they experience, and on the other hand to be able to anticipate the multi-dimensional vulnerability to crisis of individual firms. The latter involves predicting their susceptibility/vulnerability to a recessionary economic crisis across various key aspects of their financial situation. By doing so, the government can concentrate its interventions, particularly the large-scale economic stimulus programs, on the firms that are most in need of this support: those that are most vulnerable to economic crises. The capacity to predict the susceptibility/ vulnerability of various firms to economic crises across multiple dimensions is additionally exceedingly beneficial for investment firms and institutions as well. This enables them to invest in and extend loans and other benefits to firms that will be more susceptible/vulnerable to subsequent crises, so that they endure and rebound once the crisis subsides. Further, this type of prediction will be beneficial for banks and investment firms (aiding them to avoid granting loans and investing in firms that might be quite vulnerable to future economic crises); and also to firms of all industries that rely heavily on extensive supply chains: it will aid them in selecting supply chain partners (including subcontractors, suppliers, wholesale and retail merchants, and others) that will exhibit a lower susceptibility/vulnerability to forthcoming economic downturns (supply chain partners that are more susceptible/vulnerable to such crises will consequently increase the vulnerability of a firm).

In this direction we propose a methodology for leveraging to the highest possible extent data that government agencies possess concerning firms' behaviour during recessionary economic crises, as well as firms' vulnerability to them; which is based on Artificial Intelligence (AI), and includes two main components: a) initially use of unsupervised artificial intelligence techniques (clustering) in order to identify, using the abovementioned government data, the main typologies of firms with respect to the impacts that economic crisis have on them; and b) a second component that includes use of supervised learning techniques (classification) in order to predict, based on the above data, the susceptibility/vulnerability of individual firms to future economic crises. This second component enables the prediction of the multi-dimensional "impact pattern" of a firm, which includes predicted

impacts of economic crisis on several important aspects of the firm. For this purpose, using the above data a series of prediction models of various aspects of the vulnerability of an individual firm to economic crisis are constructed; as independent variables are used the characteristics of the firm, such as personnel, ICT infrastructure, innovation activities, exports, strategic standings, and economic performances as compared to competitors. To validate the proposed methodology a first application of it has been made, using open government data provided by the "Greek Statistical Authority" upon request, comprising of 363 firms' information that was collected during the Greek economic decline and crises from 2009 to 2014. The results of this validation/application were deemed satisfactory.

The rest of this research paper is structured as follows: the second section provides an overview of the background containing notions of economic crisis, open government data and AI utilization in government. Section 3 describes the proposed methodology, and then section 4 contains the validation application of the proposed methodology and the results; finally, the 5th section summarizes the conclusions.

2. Background

2.1 Economic crises

Many countries experience diverse economic crises over time, and considering the global economic landscape, all nations are vulnerable to encountering an economic crisis at some juncture in their history; in the present century we had several significant economic crises, as due to the internationalization of the economy crises appearing in one country can rapidly propagate to other countries (Allen, 2016; Baldwin & di Mauro, 2020; Keeley & Love, 2010; Knoop, 2010; Kottika et al., 2020; Loukis et al., 2021; OECD, 2009a; Saifi & Horowitz, 2023). Economic crises lead to recessions, which are significant downturns in economic activity, and can be triggered by various factors, such as: a) unstable and inconsistent long-term macroeconomic policies; b) emergence of unsustainable budgetary imbalance; c) significant inflationary pressures resulting in substantial price hikes for essential commodities such as oil and gas; d) misalignment of currency rates; e) retraction of foreign capital; f) crisis in the banking and financial institutions (Acemoglu et al., 2003). Firms are negatively affected by economic crises, as the latter result in economic recessions, leading to a decrease in the demand for most goods and services, as well as in their prices, decrease in liquidity provision by banks, etc.; so, firms react to the decrease of the demand for their products and services, and therefore of their sales revenue and liquidity, by reducing production and procurement, as well as personnel employment, with the latter leading to higher rates of unemployment, poverty, and social exclusion; furthermore, due to the reduced availability of financial resources, for the reasons mentioned above, resulting to an increase of their debts, and also higher difficulty to borrow from banks, firms decrease their capital expenditures for investments, including those in machinery, ICT, research and development, new products, etc. Possible negative consequences of this in the medium- to long-term include falling behind the technological trend, missing out on key growth opportunities, and slowing the rate of competitiveness progress. (Allen, 2016; Baldwin & di Mauro, 2020; Keeley & Love, 2010; Knoop, 2010; Kottika et al., 2020; Loukis et al., 2021; OECD, 2009a; Saifi & Horowitz, 2023).

Nevertheless, the adverse effects of economic crises vary considerably among firms (Allen, 2016; Arvanitis & Loukis, 2023; Knoop, 2010; OECD, 2009a). Certain firms have personnel with advanced educational backgrounds, with extensive expertise and experience, as well as more efficient production equipment and processes, and better digital infrastructures, so they can offer more attractive products/services of higher value-for money during the crisis, and in general adapt better to the tough crisis conditions, so they finally exhibit lower vulnerability to the crisis than other firms that are more vulnerable.

The frequent occurrence of economic crises, particularly in recent times, poses a significant and pressing challenge for governments. On one hand, they must strive to prevent these crises from happening, and on the other hand, they must take measures to mitigate their severity and the adverse outcomes they bring, such as widespread business closures, a sharp rise in unemployment, poverty, and social exclusion. These consequences can potentially lead to social unrest and political extremism. In regard to the latter, governments devise and execute enormous and expensive interventions, such as the expansive economic stimulus programs, which consume enormous quantities of financial resources (and can lead to substantial increases in public debt); they comprise (among others) a variety of financial support actions for firms, including rebates on taxes, monetary assistance, subsidies (aid), investment financial support, low-interest (or even no-interest) financing, and financial support for investments (Coenen et al., 2012; Kalinowski, 2015; Khatiwada, 2009; Taylor, 2018).

Significant governmental interventions, particularly expansive boost to the economy (stimulus) programs, are more economically viable when they are focused on the most susceptible/vulnerable businesses to the economic crisis rather than being "horizontal" (i.e., providing assistance to all firms), which can waste enormous financial resources. As stated in the Introduction, it would be extremely helpful if it was possible: a) to understand the main typologies of firms with respect to the impacts of economic crises on them; b) to predict the susceptibility/vulnerability of individual firms to future economic crises in light of their financial circumstances.

Especially with respect to the latter, it would be exceedingly practical to forecast the comprehensive "pattern" of a specific firm's susceptibility/vulnerability to economic crises. For these purposes pre-existing government data from economic crisis periods, processed through sophisticated AI, might be quite useful. In this direction our paper makes a contribution.

In the past, there has been some research that employs AI-based techniques in order to provide an early prediction and warning for economic crises. For instance (Wang & Zong, 2023), use AI/ML and currency data in order to assist private sector firms in China in early detection of crises. In (Samitas et al., 2020) is developed a method of using AI/ML and net-work analysis for creating an early-warning system for predicting financial crises, focusing on contagion risks. The benefits of using ML tools to assess the risk of fiscal crises are investigated in (Hellwig, 2021) , and a comparison is made with the standard econometric approaches that are usually employed for this purpose, concluding that the former outperform the latter. However, there is a lack of research concerning the use of AI for understanding and predicting the impacts of financial crises on firms, which constitute the primary actors of modern economies. The current investigation serves towards bridging this research gap.

2.2 Open Government Data

As mentioned in the Introduction government agencies possess large amounts of valuable data, usually developed through their operations of direct data collection from citizens and firms; for some of these data they decide to open them to the society, so that various actors (e.g. universities and research centres, firms, citizens communities, etc.) can process them, and extract additional useful insights from them as well as develop useful services; this has made a substantial contribution to the growth of the "data economy (Ali et al., 2022; Charalabidis et al., 2018; Gao et al., 2023; Van Loenen et al., 2021; Wirtz et al., 2022; Zuiderwijk et al., 2019). According to (Gao et al., 2023) “Open Government Data (OGD) refers to publishing public sector information in open and reusable formats, without restriction or monetary charge for use by society”. Most of these data are provided freely in government websites, but some sensitive data can be provided only upon request and subject to specific conditions. An increasing number of nations are formulating OGD policies and implementing targeted OGD initiatives with the following goals in mind: a) to promote economic activity that capitalizes on OGD (e.g., pioneering value-added e-services derived from the combination of diverse forms of OGD and potentially private data, and overall OG); and b) to advance social objectives (in-creased the government accountability and transparency, as well as citizen engagement and trust) (Official Journal of the European Union, 2019; Open, Useful and Re-Usable Data (OURdata) Index, 2020).

Despite the fact that these OGD initiatives have made available substantial quantities of public sector data, neither their use nor the social-political and economic value produced from them have met the initial expectations (Gao et al., 2023; Van Loenen et al., 2021; Zuiderwijk et al., 2019). This is quite negative given the large investments that have been made by governments for these OGD initiatives, as well as the loss of great opportunities that the utilization OGD could provide. As possible solutions of this problem have been proposed: a) on one hand the alignment of OGD supply with demand (i.e., the provision of the kinds of OGD that the public (citizens, firms, journalists, etc.) is really interested in), and the development of appropriate collaborations and ecosystems for the exploitation of OGD and the creation of significant societal and economical goals through these stakeholders (Van Loenen et al., 2021; Zuiderwijk et al., 2019); b) the more ‘intensive’ exploitation of the large quantities of public sector data that have been opened through the use of highly sophisticated processing techniques, such as AI techniques, in order to maximize the knowledge extraction and in general the value generation from them (Charalabidis et al., 2018; Gao et al., 2023). However limited is the research that has been conducted concerning the use of AI for increasing the generation of value from OGD. A good example of this research direction is the study described in (Tsagkis et al., 2023), which uses ML trained with OGD for the forecast of urban growth in order to improve city planning; in particular, an artificial neural network is constructed, which is used for five major Greek cities in order to make an urban growth prediction for each city for the following 12-years. Also, (Gao & Janssen, 2020) examines three instances of AI implementation for OGD, and concludes that it can lead to the generation of substantial innovation and efficiency related benefits. So, much more research is required concerning the more sophisticated and intensive utilization of the OGD using AI techniques for enhancing knowledge extraction and, in general, value generation from OGD; the current work provides a valuable addition to this particular area.

2.3 AI in Government

Over the course of the previous decade, AI has experienced significant growth in its implementation and exploitation beyond academic research centres; initially, private sector organizations and, more recently, government agencies have begun to utilize AI in their operations and decisions (European Commission. Joint Research Centre., 2022; Gomes de Sousa et al., 2019; Madan & Ashok, 2023; Medaglia et al., 2023; van Noordt & Misuraca, 2022; Zuiderwijk et al., 2021). The current automation in the government's processes and operations based on the utilization of traditional information systems methods can be extended and enhanced towards cognitive processes, through the exploitation of vast amounts of data available fed into AI algorithms, such as machine learning and deep learning ones.

Several highly beneficial applications of AI in government operations and decision making have been developed (European Commission. Joint Research Centre., 2022). For instance, the government in the fight against the tax evasion developed an automated ways to recognize citizens and businesses with a high risk of tax dodging. This application helps the governments to develop tax audits more precisely. Healthcare also utilizes AI to tackle several issues in the disease diagnosis-identification, prevention, as well as treatment of the patients. Healthcare also uses AI for clinical-related decision support systems and decision-making processes. In the social policy and crime prevention field, some of the AI uses, such as fraud identification, youth monitoring for prevention of any future risk and preventing any unwanted situation, identification of spatial crimes and patterns, face recognition from videos and images, and improving interaction with citizens through chatbots, are a few of the uses of AI, among others. In this direction the European Union initiative called "AI Watch" aims at recognizing the possible applications and goals of the AI utilization in the government's process, and disseminating them, aiming to increase the use of AI in governments (European Commission. Joint Research Centre., 2022). AI Watch highlights some specific uses of AI in the public sector; the first one is that the government uses it for the improvement in the public services provision by providing tailored and citizen-oriented services, information, and data; the second is that, governments use AI for improving the internal processes and administrative efficiencies by managing the available public resources as well as improving the quality of the process/service and reducing the overall cost of them. Moreover, there is high research interest in the AI's possible role in the government, which distinguished two possible roles:
a) Administration tasks automation through the utilization of AI, which can help in reducing the costs and increasing the efficiencies of these tasks.
b) Administration process enhancement through the use of AI augmentation, particularly duties related to top-level decision-making and policy devising, by providing AI with high-quality data to improve decision effectiveness and overall quality and performance.
There have been several studies discuss AI utilization and exploitation in the governments and their assessment methods (Gomes de Sousa et al., 2019; Madan & Ashok, 2023; Medaglia et al., 2023; van Noordt & Misuraca, 2022).

Nonetheless, it is widely acknowledged that the utilization of AI in government has only scratched the surface of its immense potential in automating, supporting, and enhancing various government functions. Furthermore, the majority of AI applications in government pertain to activities of low or medium administrative importance and financial significance (Gomes de Sousa et al., 2019), (Medaglia et al., 2023), and (van Noordt & Misuraca, 2022). As a result, substantial additional research is necessary to further exploit this enormous potential by developing new approaches and methodologies for utilizing AI in government, particularly in its most critical and expensive operations, with the aim of enhancing their efficacy and efficiency. This paper contributes in this direction towards increasing our knowledge about advanced utilization of AI in government in order to manage better one of the most important challenges it faces: the economic crises that frequently appear in this century in our economies and societies. In this direction we propose a methodology which combines the use of supervised machine learning (estimation of a prediction model of the value of a 'dependent variable' – outcome for a specific 'unit' (e.g. individual, firm, etc.) from the values of a number of 'independent variables' for the same unit, based on existing historic data for a number of units concerning both the value of the dependent variable and the values of the independent variables); with the use of unsupervised machine learning (use of existing historic data for a number of units concerning a number of variables, for the identification of possible clusters of 'similar' units, having similar values in these variables) (Russel and Norvig, 2020).

3. Proposed Methodology

The proposed methodology leverages existing data in government agencies about the behaviour of individual firms during economic crises and their vulnerability to them; these data include various aspects of impact of the economic crisis on these individual firms as main variables (e.g. impacts of various important economic aspects of the firms). Its structure is shown in Fig.1.

Initially it is important to use these data in order to understand the main typologies of firms with respect to the impact of economic crisis on them; if we find quite different typologies then we can design for each of them a different appropriate support policy and corresponding programs (mainly for the impact typologies that really require such support). For this purpose, we can use unsupervised learning techniques, such as clustering ones (e.g. k-means clustering) (Russel and Norvig, 2020), based on the above variables; the number of clusters can be identified through dendrogram or/and elbow techniques, and then in order to understand each cluster (typology) its centroid is calculated (=average values of all variables across all firms of the cluster).

Then we can proceed to the use of supervised learning techniques, such as classification ones (Russel and Norvig, 2020), based on the same data, in order to construct prediction models of the "vulnerability pattern" of an individual firm in the event of a future economic crisis. This pattern is represented as a vector, which has components the impacts of the crisis on various economic aspects of the firm (e.g. impacts on the decrease of domestic demand from other private sector firms and individual consumers, impact on the decrease of domestic demand from public sector, impact of the decrease of foreign demand, etc.):

$$IMP = [IMP_1, IMP_{2, \ldots\ldots,} IMP_N]$$

These N components can be measures in Likert scale with three or five levels of impact measurement (e.g. "not at all," "small impact", "moderate impact", "large impact" and "very large impact"); for each component a different prediction model is constructed using the available historic data.

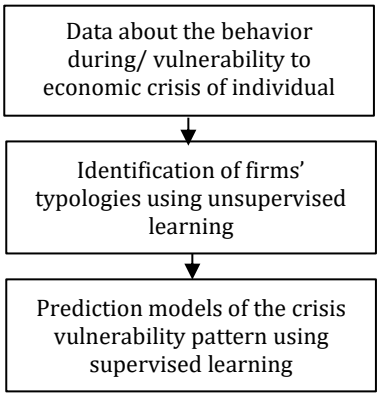

Fig.1. Structure of the proposed methodology

In particular, for each of the components of the "vulnerability pattern" IMPi we develop a predictive model that has this element as dependent variable. In order to define the independent variables of this model we have been based on theoretical foundations from economic and management science.

According to economic science, the main factors influencing a firm's output and overall performance are its labor force, which is made up of people with a variety of specializations and educational backgrounds, and its capital, which includes all types of equipment used for production and administrative tasks; the renowned production function of Cobb-Douglas is often used to quantify this connection (Douglas, 1976; Mahaboob et al., 2019; Pilat, 2004). Additionally, a variety of frameworks have been developed in the discipline of management science to outline the key elements of a firm that impact its performance. With five fundamental components—strategy, processes, people, technology, and organizational structure—the 'Leavitt's Diamond' framework is the most prominent among them (Leavitt, 1962; Scott Morton, 1991, p. 19). We can see that the 'people' and 'technology' components correspond broadly to the 'capital' and 'labour' ones of the Cobb-Douglas production function, so the other three 'strategy', 'processes' and 'structure' elements are additional (in comparison with the Cobb-Douglas production function). Therefore, the 'Leavitt's Diamond' framework is more comprehensive, so we have used it as basis and theoretical foundation for determining the independent variables of our prediction models, since it includes both the main production factors determined by the economic science and also the above three additional highly important management-oriented elements. It is reasonable to anticipate that these five pivotal components within the 'Leavitt's Diamond' framework will serve as primary determinants of a firm's performance in both typical economic conditions and during economic crises.

Therefore, each of these N prediction models (of IMPi, i=1…N) comprises five categories of independent variables:
a) Strategy: the first category of the independent variables comes from the strategy component of the 'Leavitt's Diamond' framework, and includes elements related to firm's adoption of key competitive strategies listed in strategic management literature studies, such as cost leadership, innovation, differentiation, and focus.
b) Process: the second category of independent variables covers process-related features of a firm's operations, such as complexity and flexibilities in operations.
c) People: it includes independent variables concerning the workforce of the firm in terms of education levels, particulars skills, certifications, and related attributes etc.
d) Technology: it refers to the utilization of various technologies for firm's manufacturing and administrative functions.
e) Structure: it refers to the fundamental elements of the company's organizational structure, such as the use of "organic" work organization techniques like cooperation, etc.
Additionally, a sixth category of independent variables is necessary concerning basic information about the firm, including its size, industry, and performance in comparison to rivals. Figure 2 shows the structure of these prediction models (dependent and independent variables).

For constructing each of these prediction models we can use several alternative widely used AI/ML algorithms, such as the decision tree (DT), random forest (RF), logistic regression (LR) and support vector machines (SVM) ones (Russel and Norvig, 2020), and determine the top performing one; they will be trained using available OGD (that might be freely available, or due to the sensitivity of these data available on request and under specific conditions) about individual firm's behaviour during and vulnerability to economic crisis, as well as main characteristics of them (including the ones of the main categories a) to e) mentioned above), from Statistical

Authorities or other government agencies collecting such data.

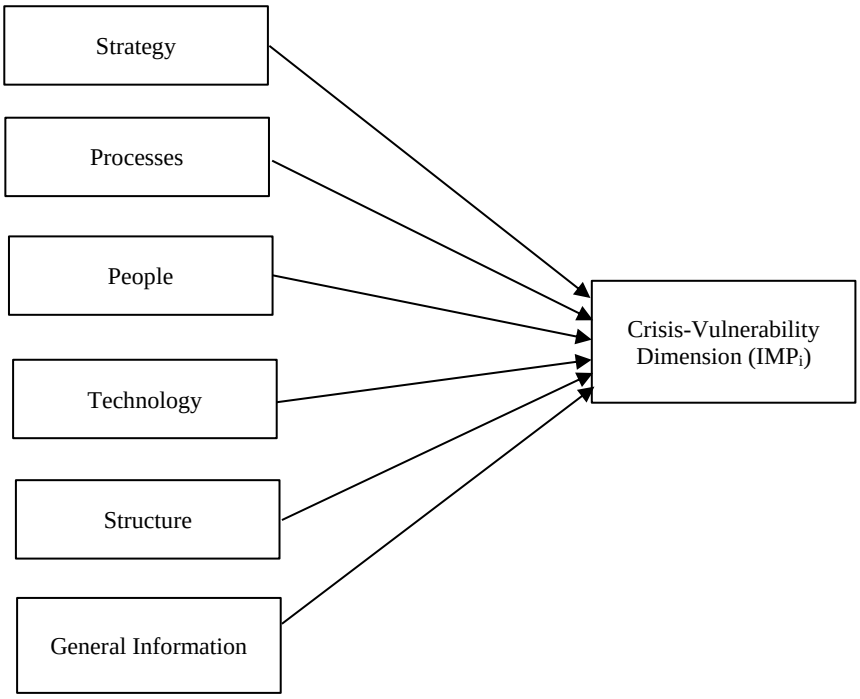

Fig. 2 - The structure for the prediction models of each of the elements of a firm's vulnerability pattern to economic crisis

Nonetheless, such datasets often exhibit several issues:
i) they tend to be noisy due to missing values;
ii) their size may not be sufficiently large to train robust and accurate machine learning models;
iii) and also, these datasets are frequently imbalanced, with some classes having a limited number of observations compared to others (this imbalance can lead to prediction models with reduced performance and potential bias).
In order to address problems ii) and ii), we include a preprocessing phase using the Synthetic Minority Over-sampling Technique (SMOTE) (Dudjak & Martinović, 2020). By filling in missing values, balancing the distribution of classes, and oversampling the dataset's existing samples, SMOTE allays these worries. This can improve the prediction model's performance and accounts for any possible bias.

Furthermore, our method starts with an exploratory data analysis (EDA) that incorporates data visualization to get a fundamental understanding of the dataset. This EDA step facilitates the necessary adjustments and informs the subsequent operations. Following the EDA, a Principal Component Analysis (PCA) is used to choose or exclude features according to their relative value (Mishra et al., 2017). This feature selection process reduces training time and enhances model performance.

4. Application

The proposed method was applied and validated using a OGD dataset obtained from the Greek Statistical Authority; it was provided to the authors upon request and with written authorization, in order to be used for research purposes, under a non-disclosure agreement. The dataset had 363 instances, each of which represented a distinct firm. It included a comprehensive list of traits and assessments for each firm, organized as follows:
- Vulnerability variables: Each firm's vulnerability to the economic crisis for the period 2009 to 2014, assessed through five variables: decrease of domestic demand from other private sector firms and individual consumers (IMP_DPRD), decrease of domestic demand from public sector (IMP_DPUD), decrease of foreign demand (IMP_DFOD), decrease of products/services prices (IMP_DPRI) and decrease of liquidity provision by banks (IMP_DLIQ). They were initially measured in a five levels Lickert scale ("not at all", "small", "moderate", "large" and "very large")
- Firm Characteristics: This part had forty variables that addressed various firm's characteristics: strategy, personnel, technology (especially digital technology), structure (including the use of "organic" forms of work organization, such collaboration), and general company information were some of these elements; this general information comprised the firm's size, as indicated by the number of employees, its industry (services or manufacturing), and a comparison of its financial performance over the last three years with that of its competitors.

All the processing of the above data described below was performed using Python language, specifically Python

3.11.7. For the machine learning tasks, we have used the open-source package within the Python environment — scikit-learn. This package contains the machine learning models and other data processing and splitting functions which are readily available to perform the supervised and unsupervised machine learning tasks, as we performed in our experimentation. Furthermore, scikit-learn supports parametric tuning; however, we used default parameters in all these experiments

The dataset's initial cause of noise was missing values; however, this was re-solved by replacing the missing values with the best values based on the variable type; for instance, the value with the highest relative frequency value was used to fill in the missing values for ordinal variables. The necessary visualizations and transformations were then used in an exploratory data analysis (EDA) to enhance data understanding. The size of the dataset—which, as previously said, included data for 363 firms—made it difficult to build a supervised ML prediction model of high prediction performance; so, as mentioned in the previous section 3, we used the oversampling and class-balancing method SMOTE to overcome this constraint.

After the above preprocessing we proceeded to the application of unsupervised learning to the above data; we conducted clustering, using the abovementioned five vulnerability variables (IMP_DPRD, IMP_DPUD, IMP_DFOD, IMP_DPRI, IMP_DLIQ), in order to examine if we can distinguish some distinct clusters – typologies of firms with respect to the above five kinds of impact of the economic crisis on them. Using both the dendrogram and the elbow techniques we identified the number of clusters; both techniques indicated the existence of three clusters. Then using this identified number of three clusters we performed k-means clustering. The results concerning the centroids of the three clusters are shown in Fig. 3 (we can see for each of the above five vulnerability variables (features) its average value over all firms of each class). We can distinguish one cluster (cluster 3 – it includes 78 firms) that experienced on average a negligible to small negative impact of the decrease of domestic public sector demand and foreign demand due to the crisis, and also a small to moderate negative impact of the decrease of domestic private sector and individual consumers' demand, as well as the decrease of products/services prices caused by the crisis; furthermore they experienced a small negative impact of the decrease of liquidity provision by banks during the crisis. We can characterize this cluster as 'low crisis-vulnerability firms' (the average value over all five vulnerability variables equals to 1,87). Also, we can distinguish another cluster (cluster 1 – it includes 118 firms) that experienced on average a moderate to large negative impact of the decrease of domestic private sector demand and the products/services prices caused by the crisis, a small to moderate negative impact of the decrease of the foreign demand, and a small negative impact of the decrease of domestic public sector demand; furthermore, they experienced a large negative impact of the decrease of liquidity provision by banks during the crisis. We can characterize this cluster as 'moderate crisis-vulnerability firms' (the average value over all five vulnerability variables equals to 2,9). Finally, we can distinguish another cluster experiencing even higher negative impacts (cluster 2 – it includes 167 firms): a high negative impact of the decrease of the domestic private sector and individual consumers' demand, as well as the domestic public sector demand, caused by the crisis; also a moderate to large negative impact of the decrease of products/services prices and the decrease of liquidity provision by banks during the crisis; and finally a small to moderate impact of the decrease of foreign demand. We can characterize this cluster as 'moderate to large crisis-vulnerability firms' (the average value over all five vulnerability variables equals to 3,45). The above clustering results indicate the existence of a large heterogeneity among the firms regarding the effects of the crisis, which necessitates the design and implementation of different policies and programs for each cluster-typology of crisis negative impacts, especially for clusters 1 and 2 (placing emphasis on supporting them to cope with the decrease of liquidity provision by banks during the crisis).

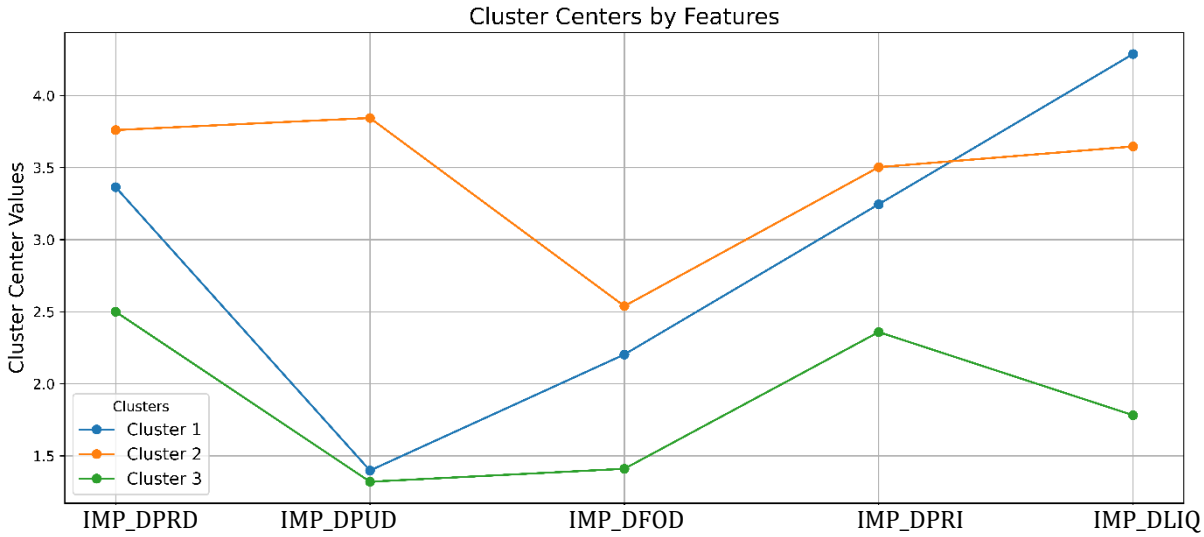

Fig.3. The centroids of the three clusters

Then we proceeded to the application of supervised machine learning to the above data: we used AI/ML algorithms in order to predict the 'vulnerability pattern' of an individual firm: we constructed for each of the five vulnerability variables one prediction models, having as independent variables the forty firm's characteristics mentioned in the beginning of this section (concerning firm's strategy, personnel, use of digital technologies, structure and general firm information). Due to the small size of our dataset (data for 363 firms) we focused on a less-detailed prediction of these five vulnerability variables, and for this purpose they were converted into binary form, with the first three values (not at all, small, moderate) being marked as "non-vulnerable" and the other two (large, very large) as "vulnerable". The dataset was divided into two subsets: a training dataset containing 70% of the samples and a testing dataset containing the remaining 30% of the samples; then another division of the dataset was made: a training dataset with 80% of the samples, and a test dataset with the remaining 20%. For both cases we used the training sets in order to construct AI/ML models, making use of four widely used algorithms: Decision Tree (DT), Random Forest (RF), Logistic Regression (LR) and Support Vector Machines (SVM). In each case the corresponding test set was used in order to evaluate the prediction performance of each of these AI/ML models. The results, including prediction accuracy, precision, recall, and F-score, are presented in Table 1, with bold highlights indicating the best-performing algorithm for each of the five crisis vulnerability variables. We have repeated the same for the prediction of firm's cluster membership (i.e. whether it will belong to cluster 1, 2 or 3 = whether in a future crisis it is going to exhibit low, moderate or moderate to large crisis-vulnerability) using the same firm's characteristics as independent variables.

Tab. 1 – Evaluation of Prediction Performance of the AI/ML models for each of the five crisis vulnerability variables

Variable.e.	Algorithm	Split Ratio							
		Performance with 70-30 (weighted average precision, recall, and F-score)				Performance with 80-20 (weighted average precision, recall, and F-score)

Cluster	DT	0.6500	0.66	0.65	0.65	0.6400	0.65	0.64	0.63
	RF	**0.7600**	**0.76**	**0.76**	**0.75**	**0.7400**	**0.74**	**0.74**	**0.73**
	LR	0.5500	0.54	0.55	0.55	0.5500	0.54	0.55	0.54
	SVC	0.6900	0.70	0.69	0.69	0.6900	0.70	0.69	0.69

We can see that for all the crisis vulnerability variables the highest prediction performance is achieved through the Random Forest (RF) algorithm; these prediction performances are high (especially if we take into account the small

size of the available dataset), ranging (for the 70-30 training-test set case) from an accuracy of 0.9266 for IMP_DPRD and 0.9216 for IMP_DLIQ, to 0.8616 for IMP_DFOD. For the cluster membership again the RF algorithm achieves the highest prediction performance, which is however lower, with an accuracy equal to 0.76 (which was expected as now the prediction provided by this model is more detailed than in the previous ones: it has to predict one out of three possible values, while the previous models had to predict one out of two possible values); nevertheless it is satisfactory, taking into account the small size of the available dataset.

5. Conclusion

In the preceding sections of this paper, we have developed a methodology for sophisticated advanced leveraging of data that government agencies possess concerning firms' behaviour during and vulnerability to recessionary economic crises, using a combination of AI techniques, both unsupervised and supervised ones, the latter in conjunction with the Synthetic Minority Oversampling Technique (SMOTE) to optimize their performance. The primary goal of the proposed methodology is to provide valuable support and enhance the crucial and resource-intensive types of interventions undertaken by governments during economic crises, in order to mitigate their adverse consequences on firms (including large-scale economic stimulus programs). It quite important to bolster the effectiveness of such interventions and focus them on the most susceptible businesses affected severely by the economic crisis, thereby reducing the detrimental impact of economic crises.

From the two main roles that AI can play in government discussed in Section 2.3, namely automation and augmentation, our methodology aligns with the latter. Its primary objective is to augment and enhance the decision-making processes of competent government agencies when it comes to identifying firms to be supported through extensive and costly programs and interventions implemented during economic crises. This is particularly crucial in the context of large-scale economic stimulus programs. By offering an additional input, specifically the typologies of firms with respect to their behaviour in/vulnerability to economic crises, and the prediction of the vulnerability pattern of individual firms to economic crises, our methodology proves highly valuable for facilitating the critical decisions involved in designing and implementing policies and programs for mitigating the consequences of economic crises for firms, as well as in selecting firms to support, especially when numerous firms submit applications for such assistance.

The proposed methodology is useful not only to government agencies, but also to banks and investment firms as well, as it strengthens and improves their decision-making procedures when it comes to identifying firms eligible for loans or investments; our methodology enables them to identify firms that will be particularly vulnerable to future economic crises (which have become frequent in this century), which makes granting loans to or investing in them highly risky (this predicted vulnerability to future crises can be one of the criteria they use for selecting firms eligible for loans or investments). Our methodology also extends its utility to firms across various sectors that heavily rely on extensive supply chains: it improves and supplements the process of choosing supply chain partners, by enabling them to take into account their predicted vulnerability to future crises and avoid supply chain partners (e.g. suppliers, wholesalers, etc.) exhibiting high risk of vulnerability to future economic crises.

Furthermore, OGD provided on request from the Greek Statistical Authority, which includes data from 363 firms for the turbulent 2009–2014 period of the severe Greek economic crisis, has been used for a first application and validation of the suggested methodology, which gave satisfactory results.

The research presented in this paper carries substantial implications for both research and practice. In the realm of research, it offers significant contributions to two crucial research streams. Firstly, it enriches the ever-expanding research on the utilization of AI in government by introducing a novel approach that leverages AI/ML to bolster a vital government activity of high economic, social, and financial significance: government intervention for mitigating the impacts of crises on firms. Secondly, it extends the OGD research by presenting a methodology that enhances the economic and social value derived from OGD through advanced processing of them through AI-based processing techniques (unsupervised and supervised ML). In the context of practical applications, this research equips government agencies, and also banks, investment firms, and businesses across various sectors heavily reliant on extensive supply chains, with a valuable tool for augmenting and enhancing highly important decision-making.

Nonetheless, further research is warranted in several critical directions. Firstly, there is a need for expanded application of the proposed methodology, encompassing larger datasets from diverse national and sectoral contexts that have encountered varying types and intensities of economic crises. This will enhance the methodology's robustness and applicability. Secondly, exploration of alternative pre-processing algorithms, such as over-sampling and class-balancing algorithms, missing data treatment techniques, as well as more advanced AI/ML algorithms, including deep learning ones, is essential to broaden the methodology's capabilities. Lastly, investigating the integration of OGD with data from other sources, such as data from other government agencies and private firms, including private business information databases, is vital to enrich the information available about firms. This expanded data could potentially enhance the prediction performance of a firm's vulnerability

pattern to economic crises, as well as provide deeper insights concerning heterogeneities among firms with respect to their behaviour in/vulnerability to economic crises.

Abstract. This work investigates the application of Active Learning methodologies for data annotation in Named Entity Recognition (NER) tasks mainly when used in documents from the legal domain in Portuguese. Its aim is to determine an algorithm able to improve the efficiency of the annotation process and reduce the human cost involved, without compromising the quality of the classifiers trained in these corpora. Three sample selection methods were explored: (i) Multi-Criteria Active Learning, using informativeness, representativeness, and diversity as selection criteria, (ii) Dynamic Selection Guided by Entity Volume, and (iii) Random Sentence Selection (used as a baseline for evaluating the other two). The study was conducted using the BERT model for classification, employing different amounts of labeled data for each approach (annotation budgets). The results show that, although Multi-Criteria Active Learning performed better in some scenarios, Dynamic Selection Guided by Entity Volume consistently showed good performance, especially for low annotation budgets, in addition to being computationally more efficient. Thus, the analysis of the results suggests that the volume of named entities is a good predictor for selecting informative samples. This study contributes to the Active Learning field by applying these techniques to modern language models and providing efficient solutions for reducing costs in data annotation for Named Entity Recognition.

1. Introduction

The exponential growth of data generated daily poses a significant challenge for the efficient retrieval of information. The ever-growing magnitude of information collections has made subsequent querying increasingly

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

unfeasible for humans. This difficulty is particularly pronounced when the target of the query involves finding information not based on a formal label (such as a book title) but rather on some description of the desired information. One domain where this challenge is exacerbated is the legislative domain. The Brazilian Chamber of Deputies alone has analyzed over 144,000 projects, each generating documents detailing the process. Moreover, during the drafting of each project, it is necessary to consult related documents such as laws and bills, which are numerous and dispersed among a vast number of unstructured documents (Brandt, 2020).

To address this problem, investments have been made in developing tools that assist in the process of information retrieval from document collections using Natural Language Processing (NLP) techniques—a subfield of artificial intelligence aimed at solving problems related to the automatic understanding and generation of data in human natural languages (Albuquerque et al., 2022). One of the challenges in NLP is automating the process of Named Entity Recognition (NER), which involves detecting textual elements representing names of objects, concepts, etc., and potentially classifying them by entity type. The ability to perform this task automatically and reliably is highly desirable, as much of the subject matter in sentences can be identified solely by the named entities mentioned in the text. For this reason, NER is a widely used technique in various activities, including information retrieval. (Jehangir et al., 2023) However, there are no morphological elements that allow the creation of deterministic algorithms to reliably detect these entities (like the A* algorithm for determining optimal routes). This necessitates the application of sophisticated techniques to achieve the goal.

For this reason, the current state-of-the-art involves the use of Machine Learning techniques. Mitchell, 1998 defines Machine Learning by describing the concept of a "computer learning" as follows: "A computer program is said to learn from experience E with respect to some task T and performance measure P, if its performance on T, as measured by P, improves with E." Machine Learning algorithms are thus designed to improve over time without requiring humans to continuously provide explicit instructions for improvement, such as conditionals (which would require humans to have such information and enough time to account for all possible cases, which is often unreasonable). Machine Learning algorithms require experience (training) to improve their performance to an acceptable level, often surpassing deterministic algorithms or even human experts. The most commonly used machine learning paradigm for NER algorithms is supervised learning, where the algorithms are provided with a list of possible "inputs" along with the expected output for each input. After adapting the resolution algorithm (often achieved by updating the mathematical model used to represent the task at hand), the program should demonstrate improved performance (typically defined as "making fewer errors" when exposed to corresponding inputs). However, obtaining these input-output pairs (referred to as "labeled examples" or "annotated examples") is often a costly process, requiring various domain experts to ensure that the annotation is completed within an acceptable time frame and error rate. This process can be financially expensive or even unfeasible due to time and labor constraints. Such costs frequently become prohibitive, especially when considering that the state-of-the-art for various tasks, such as image processing and NLP, involves programs based on more sophisticated models. These models, while achieving higher performance, often require enormous labeled datasets. For example, during the training of the BERT (bi-directional encoding representations from transformers) model, which was once state-of-the-art for NER tasks, Devlin et al., 2018 used the CONLL-2003 dataset, which contains about 300,000 tokens.

Among the initiatives to address problems related to large-scale legislative domain data using NLP is the Ulysses project—a set of initiatives aimed at leveraging artificial intelligence to support legislative activities and improve the relationship between the Brazilian Chamber of Deputies and citizens. Various systems have been explored within the project, including systems that utilize NER models in their architecture to enhance information retrieval systems for use by the Legislative Consultancy of the Chamber of Deputies, as explored by Albuquerque et al., 2024. Therefore, achieving optimal performance for these systems requires highly performant NER models, which, as mentioned earlier, necessitate the availability of a large annotated domain-specific dataset. Although there are large relevant datasets, such as the recently introduced Ulysses Tesemõ by Siqueira et al., 2024 (an extensive corpus in the legal and governmental domain with over 3 million documents sourced from various origins), annotating corpora of this magnitude is unfeasible. Even if only a sample of it is annotated, the decision on which samples to annotate is often arbitrary and potentially inefficient for building a corpus that enhances the performance of classifiers trained with these samples (Albuquerque et al., 2022).

Solving this problem is the goal of the field of Active Learning (AL). The methodology employed by active learning involves generating a selection criterion based on a pre-trained model capable of automatically selecting the best inputs—that is, those whose respective outputs, if labeled and provided to a model, would

result in the greatest improvement in its performance, often using, in the NER domain, its uncertainty regarding the labels of the entities it classified. Ideally, this would produce the best possible model by providing the smallest number of labeled examples. This would reduce annotation effort (and, as a side effect, also reduce algorithm training times), making the use of Machine Learning algorithms via supervised learning more accessible (de Sá Vitório, 2020). This work aims to determine an effective active learning algorithm to be employed in the expansion of corpora in the legislative domain in Portuguese intended for training modern named entity recognition models, efficiently reducing the amount of data to be manually labeled for the creation of such models that have a vast array of applications in the streamlining of legislative-related government tasks. To achieve this goal, algorithms will be proposed and implemented that consider different sample selection criteria described in prior literature. These algorithms will be applied in the context of corpus expansion for NER in the legislative domain, with the aim of determining:

- The best algorithm for executing active learning aimed at corpus expansion for training named entity recognition models in the legislative domain;
- The effectiveness of using the proposed attributes for sample selection compared to the annotation of random samples (effectively the non-use of active learning);
- The best hyperparameters for the selected algorithm, given the proposed task.

2. Background and Related Work

In this chapter, a literature review is presented, highlighting previous approaches to reducing the annotation effort required for generating a dataset capable of creating an efficient NER classifier using active learning-based techniques. These serve as the foundation for the methodologies proposed and evaluated.

2.1. Less is More: Active Learning with Support Vector Machines

One of the pioneers in using active learning for text classification had it's main innovation being the use of a simpler metric for selecting annotation candidates: while previous studies employed complex statistical methods to determine the impact of including an example in the training corpus (often requiring retraining the model multiple times considering all annotation possibilities for each candidate), the author proposed that the informativeness of an example should be considered as simply inversely proportional to its margin relative to the hyperplane separating the classes in the current model, given that the model used was an SVM (Support Vector Machine) (Schohn & Cohn, 2000).

The proposed algorithm was tested on document classification tasks using the "20 Newsgroup" corpus, which contains various posts from different online discussion groups. The goal was to perform binary classification on data subsets drawn from any two of the twenty discussion groups. Additionally, the algorithm was tested on topic classification of documents using a dataset of news articles from the Reuters-21578 Distribution 1.0 corpus.

The results were promising, as the learning curves were consistently better for active learning than for the case in which training examples were randomly selected. In some cases, the model's performance with a small number of selected examples even surpassed the performance achieved when using the entire dataset. This suggests that, for certain models, a smaller set of meaningful examples may offer better generalization capability than simply using large random samples.

2.2. Multi-Criteria-based Active Learning for Named Entity Recognition

In the first work in the area of active learning for named entity recognition (NER), the authors aimed to propose an active learning approach based on three criteria and to apply it effectively to facilitate the training of NER models, with the goal of minimizing human annotation effort by selecting the most valuable examples for labeling (Shen et al., 2004).

To maximize the contribution of selected examples, the authors proposed, in addition to informativeness, to also consider representativeness and diversity. To incorporate these three selection criteria at the entity level, two algorithms were proposed. The first aims to ensure representativeness and diversity of the samples with

respect to the entire corpus through clustering techniques, based on a similarity metric between tokens. The second proposes a scoring system that weighs informativeness and representativeness using global metrics and then iteratively checks whether the diversity of the selected sample matches the established standard.

The algorithms were tested and compared against random selection and selection based solely on the most informative entities. These tests involved training several SVM models for NER using two corpora for comparison: GENIA (biomedical, containing protein-related names) and MUC-6 (news domain, containing names of people, places, and organizations). After initial training using only part of each corpus to create initial models to determine informativeness, the algorithms and number of selected entities were varied, and additional training and performance testing were conducted using the new examples.

The results were promising, showing that it is possible, using active learning, to select samples comprising only 20% of the corpus size and still achieve performance comparable to a classifier trained on the full dataset (F1-Score of 63.3, which is low by current standards). Moreover, it was concluded that the algorithm which checks for local diversity consistently outperformed the others, and that the active learning process more effectively reduced the required sample size for MUC-6. This suggests that the technique's performance may depend on the complexity of the target task.

However, this work did not explore the effect of varying the hyperparameters of the proposed algorithms. It is also noteworthy that the methods select at the entity level; therefore, in a real-world scenario, entities would be sent for annotation in isolation. Nonetheless, it is important to highlight that the lack of context can hinder the performance of human annotators.

2.3. Accelerating the Annotation of Sparse Named Entities by Dynamic Sentence Selection

In 2008, a paper presented an active learning-based technique that shares the same use case—reducing the number of manually labeled examples required through intelligent sample selection. To this end, it also utilizes feedback from a previously trained classifier for the target task (Tsuruoka et al., 2008).

However, the suggested method diverges from classical active learning by not using uncertainty-based selection criteria. Instead, it selects examples based on the number of named entities that the model predicts exist in the example. This technique is based on the premise that named entities are sparse in the domain where it is applied. Therefore, for better performance, examples containing the largest number of entities should be prioritized.

Thus, the method consists of iteratively selecting sentences with the highest number of predicted named entities and sending all these selected sentences for token-level annotation by a human annotator. The process is repeated until the estimated fraction of annotated named entities reaches a desired value.

Experiments were conducted using a CRF (Conditional Random Fields)-based probabilistic graphical model classifier and the NLPBA (biomedical, a variant of GENIA containing protein names) and CoNLL-2003 (general domain) corpora. It was found that a reduction of approximately 52.4% in annotated sentences was possible to annotate 99% of the named entities. However, the impact of the remaining 1% of unannotated entities, or the effect of these samples on classifier performance, was not explored.

2.4. Active Learning with Pre-trained Language Models for Named Entity Recognition in Requirements Engineering

In 2024, it was published an article about an experiment evaluating active learning techniques for NER using a BERT classifier (a modern model based on transformers, the technology behind state-of-the-art models for various NLP tasks). These techniques were based on informativeness criteria, all derived from the probability distribution provided by the model when predicting the label of a candidate token for manual annotation (Riesener et al., 2024).

The criteria used for sample selection were "least confidence" (token with the lowest probability for the class it was assigned), "margin sampling" (token with the largest difference between the two most probable classes), and "entropy-based sampling." Since the selection for annotation occurred at the sentence level, while the

scores were at the token level, a ”weakest link” policy was used, where a sentence’s informativeness was defined by the informativeness of its most informative token.

Experiments were conducted on NER tasks using datasets with aerospace domain documents from various sources, where the performance of the different techniques across various sentence budgets was compared to that of random sampling.

The results indicated that ”margin sampling” was the most effective technique and confirmed that results similar to those obtained with the full corpus could be achieved using only a fraction of the data (36% in the experiments), even for tasks involving deep learning models.

3. Research Methods

This study aims to evaluate the use of specific criteria (informativeness, representativeness, diversity, and entity volume) for sentence selection to support manual annotation through two active learning algorithms, with the goal of improving named entity recognition (NER) models. The basic workflow of the study is illustrated in Figure 1.

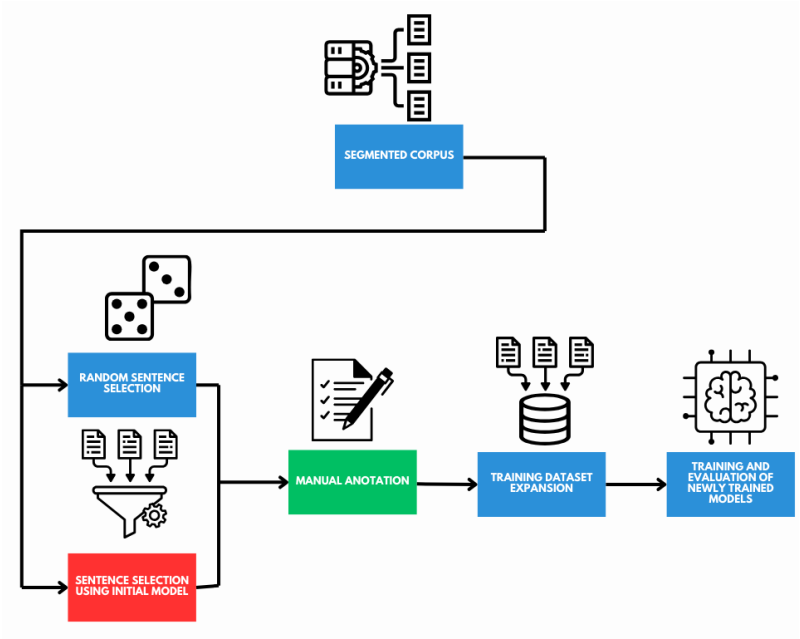

Fig. 1 – Research Flow Schematic

However, the selected dataset, UlyssesNER-Br, is pre-labeled. Thus, the study evaluates model improvement as it is progressively exposed to different samples of this corpus during training, using varying methodologies and sample sizes to define the training sets. The initial model, used to guide the selection criteria, is pretrained on a fixed sample, achieving low performance compared to the results obtained when trained on the entire corpus.

To achieve this, two algorithms (Multi-Criteria Active Learning and Dynamic Selection Guided by Entity Volume) will be implemented, as detailed in the following subsections. Using the initial model, all proposed algorithms will be executed multiple times, varying hyperparameters and sample sizes to generate diverse training datasets. After retraining the model by concatenating each selected sample with the initial one, the performances will be compared among the different approaches, against a baseline trained on randomly selected samples, and the potential performance gains will be assessed.

3.1. Corpus

The corpus used in these experiments, both for training the initial model used in the selection criteria and for providing sentences to be selected via active learning, is UlyssesNER-Br.

UlyssesNER-Br is a dataset developed for named entity recognition (NER) within the legal domain in Portuguese, as part of the Ulysses project, and is publicly available in an online repository. Entities in this dataset are annotated according to 18 entity types, organized into 7 categories, all of which are relevant for information retrieval efforts in legislative texts, as outlined in Table 1 (Albuquerque et al., 2022).

Initially, the dataset consisted of legislative bills retrieved from the Brazilian Chamber of Deputies' website and internal legislative consultation requests (these being the objects referenced by the entities "FUNDlei" and "FUNDprojetodelei," respectively). The dataset was subdivided into two corpora: the PL-corpus and the ST-corpus. However, the ST-corpus was deemed confidential and was not made publicly available; thus, it was excluded from this study.

Later, the corpus was expanded the dataset to include the "C-corpus", which comprises informal comments made by citizens on legislative bills, extracted from a web platform provided by the Chamber of Deputies. This expansion aimed to test the hypothesis that exposing the model to formal sentences from the other two corpora could enhance the predictive capacity of a model trained on a same-domain but informal corpus. This hypothesis was confirmed by the experiments published in the same article (Costa et al., 2022).

Finally, the issue of data leakage present in the PL-corpus was addressed and a higher-quality version of the corpus was provided (Nunes et al., 2024). This updated version was used in this study, along with an updated version of the C-corpus, containing more annotated documents (da Costa, 2023).

3.2. Classifier

The named entity recognition model used in this work was the HuggingFace implementation of the BERT architecture, specifically for token classification, called "AutoModelForTokenClassification" (Hugging Face, 2019). More specifically, the model employed was BERTikal, a checkpoint (pre-trained BERT model) created by training the "BERTimbau base cased model" on a corpus of Brazilian legal documents (Polo et al., 2021). BERTimbau, in turn, is a checkpoint developed by training a BERT model on the BrWaC corpus, short

for "Brazilian Web as Corpus," a large Portuguese-language dataset obtained via web scraping (Souza et al., 2020).

This model was repeatedly fine-tuned (training a classification layer using the BERT model embeddings generated for each token sequence as input) with the UlyssesNER-Br corpus so that it could recognize the named entities of interest. It was then employed in the active learning processes evaluated in this work, including both the selection of sentences for annotation and the evaluation of the quality of classifiers trained using such samples.

3.3. Multi-criteria Active Learning

The first three criteria to be explored are informativeness, representativeness, and diversity (the latter two obtained using similarity measures between tokens). These criteria are incorporated into a single algorithm, with the weight assigned to each controlled by hyperparameters.

This algorithm was adapted from previous ones to select not only entities for annotation but also textual elements containing them, with a granularity arbitrarily defined by the user of the active learning method (in this study, sentences are used) (Shen et al., 2004). Unlike the original work, where the metrics of each token in the entity are aggregated, this study considers the highest score among all tokens in a sentence as representative of the sentence's overall value. This approach aims to facilitate scalability for various granularities and avoid introducing arbitrariness into the metrics, similar to more recent methodologies (Riesener et al., 2024).

Informativeness is a criterion commonly used in classical active learning methods (Schohn & Cohn, 2000). An example is considered highly informative for training if the respective model exhibits high uncertainty in its classification. This information can be extracted directly from models that provide the probability distribution of possible classes for a given token. As such, informativeness is calculated as follows in the Equation 1:

$$\text{Informativeness}(u) = \text{Uncertainty}(u) = 1 - \mu\left(u, \left(\arg\max_{E} \mu(u, E)\right)\right) \tag{1}$$

Where μ is the token and $\mu(u, E)$ is the probability that the token μ belongs to class E. Since the token is classified into the class with the highest probability, the formula calculates the probability of the token belonging to any class other than the chosen one.

A min-max normalization is also applied to the scores to produce values more representative of the token's informativeness relative to others, as shown in the Equation 2:

$$\text{Informativeness}_{\text{normalized}}(u) = \frac{\text{Informativeness}(u) - \min}{\max - \min} \tag{2}$$

Where min and max are the smallest and largest informativeness values obtained in the corpus, respectively.

For the model used (BERT), the predicted probability distribution for each token's classes can be easily extracted. Hugging Face's implementation (Hugging Face, 2019), used in this study, provides logits (values from the final classification layer, one for each possible class, with the largest value indicating the predicted class). By applying the Softmax function, a corresponding probability distribution can be obtained.

To avoid annotating outliers—entities that, despite high informativeness, are very rare and thus provide little value for frequent model usage—representativeness is considered. An example is representative if it is, on average, highly similar to other tokens.

The similarity is calculated using the token representation provided by BERT (the final layer before the classification head), which incorporates semantic information. For a pair of tokens, similarity is calculated using cosine similarity as in Equation 3:

$$\text{Cosine Similarity}(A, B) = \frac{A \cdot B}{\|A\|\|B\|} \tag{3}$$

Where A and B are the two vectors (in this case, token embeddings) that will have their similarity evaluated, the numerator represents the dot product between them and the denominator represents the product of their respective euclidean lengths. Cosine similarity produces a value between -1 and 1, indicating the similarity between two vectors (Manning et al., 2008). The representativeness score is then defined as the average similarity of a token to all others in the corpus as in Equation 4:

$$\text{Representativeness}(u) = \frac{\sum_{v \in \text{dataset}} \text{sim}(u, v)}{|\text{dataset}|} \tag{4}$$

A min-max normalization is also applied to representativeness scores, similarly to informativeness.

To avoid annotating redundant entities—those that, despite being highly informative, are very similar to others already selected and thus do not add new information to the model—diversity is incorporated. An example is considered highly diverse when it has low similarity to other selected examples.

Diversity is ensured by discarding selected tokens that have a similarity above a certain threshold with any other selected tokens.

The algorithm itself involves calculating informativeness and representativeness scores for all tokens in the corpus, combining them using a weighting parameter λ (the weight assigned to representativeness) as shown in Equation 5:

$$\text{score}(u) = (1 - \lambda)\,\text{Informativeness}_{\text{normalized}}(u) + \lambda\,\text{Representativeness}_{\text{normalized}}(u) \tag{5}$$

Sentences (or other textual elements containing the token, depending on the chosen granularity) are then iteratively selected for annotation in descending order of their scores. Sentences are not repeated, and tokens are discarded if their similarity to any already selected token exceeds a threshold γ. The algorithm is illustrated in Figure 2.

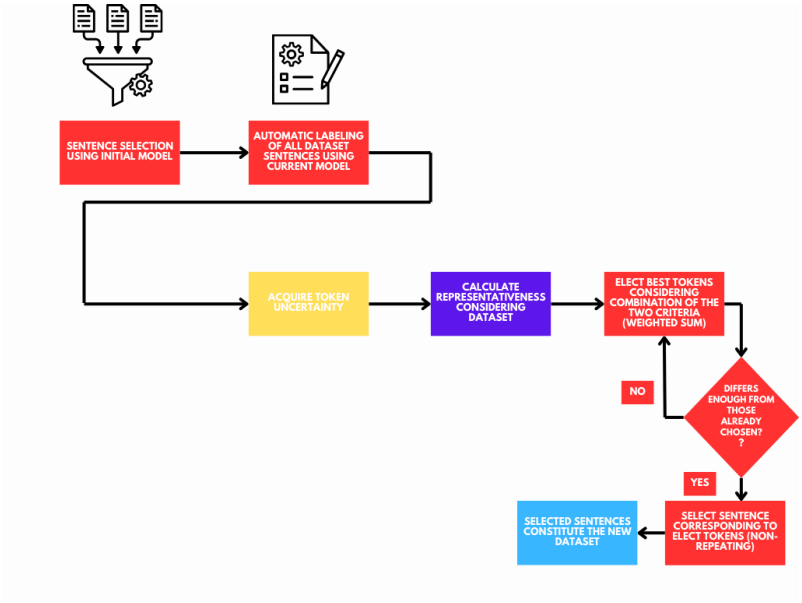

Fig. 2 – Multi-criteria Active Learning Pipeline Schematic

It's noteworthy that, by the definition given in Equation 4, the calculation of the informativeness value of a single token includes n cosine similarity calculations, in which n is the number of tokens in the dataset. This

makes the informativeness calculation complexity proportional to the size of the dataset as a whole, which is unique among all the criteria used in this study. Consequently, in order to calculate the representativeness of all n tokens in the dataset, in order to be able to start the process of selecting sentences, kn^2 cosine similarity operations are needed (where k is a constant to account for basic optimizations), leading to the representativeness calculation part of the algorithm being considered of quadratic time complexity with regards to the total number of tokens in the dataset of sentences to be forwarded to annotation. This could lead to poor scalability, because, as the pool of sentences one can choose for labeling grows (the use case of interest for active learning), the time taken to calculate representativity may become prohibitively large.

3.4. Dynamic Selection Guided by Entity Volume

The fourth criterion to be explored is solely the predicted quantity of named entities present in the analyzed sentence. This criterion is addressed using an algorithm adapted from Tsuruoka et al., 2008. This information can also be obtained directly from models that provide the probability distribution of possible classes for each processed token (such distribution is derived similarly to that used for informativeness calculation, as described earlier).

To calculate this, the expected value for each entity class is considered as fractional occurrences of the entity. The total number of entity occurrences across all tokens in the same sentence is then summed as in Equation 6:

$$\text{Entity Volume}(S) = \sum_{t \in S} (1 - \mu(t, O)) \tag{6}$$

Where S is the sentence, t is the token, and $\mu(t, E)$ is the probability of token t belonging to class E. The null class O corresponds to tokens that are not named entities.

Since all sentences are considered to have the same cost, the selection algorithm involves simply counting the number of entities using the method described above and selecting those sentences with the highest entity count.

The algorithm is illustrated in Figure 3.

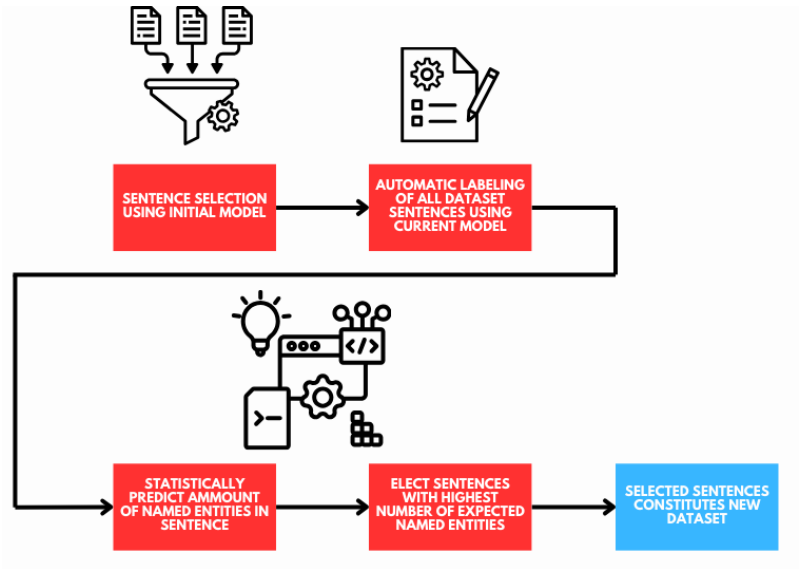

Fig. 3 – Dynamic Selection Guided by Entity Volume Pipeline Schematic

3.5. Experiment Structure

Initially, the classifier is trained to classify all 18 different types from UlyssesNER-Br except "FUNDsolicitacaotrabalho" (since no instance of it occurs in the specific corpora used). This initial process will be done using the C-corpus with an 80/20 train-validation split. Afterward, using the generated model, samples are

extracted from the PL-corpus for the three proposed methods: the two described in this chapter and random element selection. Specifically, for the Multi-Criteria Active Learning method, different variations are considered, adjusting the values of its hyperparameters λ and γ. The parameter λ (corresponding to the weight of the representativeness criterion) will be tested for values of 0 (no representativeness), 0.25, 0.5, and 0.75. λ (representing the diversity criterion) will be tested, due to computational and time constraints, only for the cases of 0 (no diversity) and one non-zero value determined through inspection during the experiment, based on the similarity values among tokens present in the dataset.

For each method or variation, four samples will be taken, consisting of 500, 1000, 1500, and 2000 elements for annotation. These elements correspond to the natural division of the dataset, typically segmented by sentences, which in this study are assumed to have equivalent annotation difficulty given the contextual requirements for entity annotation.

Afterward, several classifier training sessions will be conducted using all possible combinations between a generated sample and the C-corpus. Training follows a k-fold cross-validation approach, where the model is trained k times (in this case, 5 times), alternating the portion of the data used for testing, with the remaining portions used for training. This approach yields statistics on the classifier's average performance for the sample generated by each active learning algorithm, mitigating the effects of randomness during training (Scikit-learn, 2024).

The metrics used to compare the performance of the models trained during the experiments are the F1-score and the coefficient of variation. The F1-score is a widely used metric for evaluating classification models, especially in scenarios where class imbalance is present. It is defined as the harmonic mean of precision (the proportion of correctly predicted positive instances out of all predicted positives) and recall (also known as sensitivity, defined as the proportion of true positive instances identified out of all actual positives) (Scikit-learn, 2024).

The coefficient of variation, on the other hand, is the percentage that the variance represents relative to the mean value of the data. This metric is important because it allows us to favor the methods that consistently deliver good results, addressing the fact that focusing solely on average performance can obscure variability in outcomes.

Finally, to ensure greater robustness in the analysis of results, hypothesis tests are conducted using Welch's t-test. This test compares the location parameters (typically the means of normal distributions) of one or two samples. Unlike the more common Student's t-test, Welch's t-test does not assume that the samples have equal variances or sizes, making it more flexible and suitable for real-world data scenarios (Navarro, 2022).

4. Results and Discussion

4.1. Experimental Results

The experiments described earlier tested the three proposed algorithms (Multi-Criteria Active Learning with different weights for representativeness and with or without the diversity criterion, Entity Volume-Oriented Dynamic Selection, and random sentence selection). Samples were generated for training, and following the k-fold cross-validation methodology previously outlined, five fine-tuning processes of the BERT model were conducted, starting from the pre-trained BERTikal model introduced in the previous section. Figure 4, 5 and 6 shows the average F1-score metrics of each of the five models generated, corresponding to each training sample.

It should be noted that each trace represents a configuration of the active learning algorithm. Thus, they illustrate the model's performance evolution as larger training samples are allowed.

Visual analysis of the results reveals that, as expected, all algorithms provided an apparent improvement, albeit marginal, over random selection, except for the multi-criteria algorithm configuration that disregarded diversity and assigned the highest weight to representativeness. This result can be explained by the fact that this configuration favors the creation of a homogeneous sample, which therefore offers little new information to the model (justifying its inferior performance compared to random sampling, especially for larger data sample sizes).

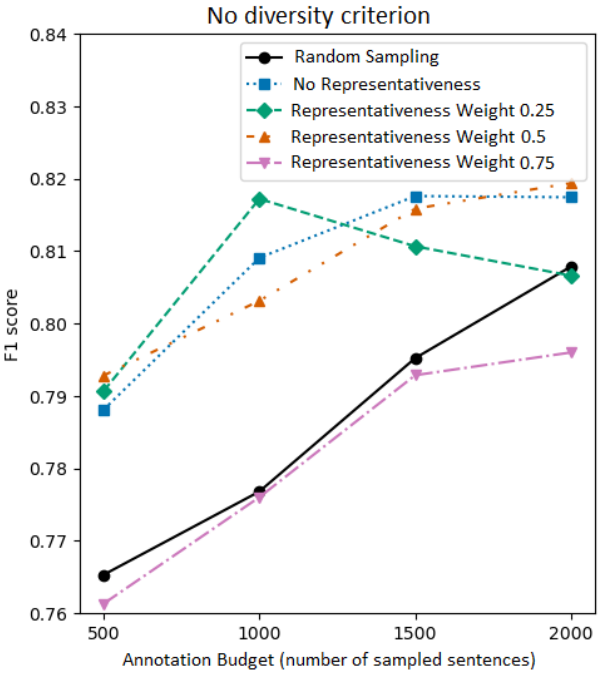

Fig. 4 – Graphs containing the performance of the multi-criteria method without diversity

Regarding the multi-criteria algorithm, although applying the diversity criterion seemingly corrected the issues mentioned above for cases with excessive weight given to representativeness—enabling the model to marginally outperform random sampling—it generally resulted in worse performance on average when diversity was considered. This difference was more pronounced for low-budget scenarios, diminishing as the budget increased. However, this reduction may be attributed to the exhaustion of options, leading the algorithms to select from the same examples (as the PL-Corpus contains only 2,527 data entries).

On the other hand, analyzing the entity volume-oriented algorithm reveals that it performed superiorly, achieving the best model with the smallest number of entries, with an average F1-score of approximately 0.795, about 0.03 higher than the average for random samples with the same budget. The other algorithms that performed better with low budgets only achieved an advantage of approximately 0.015 over random selection. Furthermore, despite the reduction in the advantage relative to random selection with increasing budgets, the difference consistently remained no less than 0.01.

Finally, the entity volume-oriented algorithm is considered superior not only due to its better performance with smaller budgets but also because of its greater simplicity and faster execution. It does not require computationally expensive steps, such as the representativeness calculations necessary for multi-criteria active learning, nor does it depend on optimizing hyperparameters specific to the corpus properties. Instead, it relies only on the assumption of named entities' sparsity being valid.

These results suggest that the predicted volume of named entities is a better predictor of good examples to include in the sample, although informativeness (alone) and representativeness (when properly weighted) can also serve as good predictors, despite the latter being computationally costly. Diversity, however, did not prove to be a good predictor. On the contrary, within the limited scope explored in this study, it was detrimental to the algorithm's performance.

However, it is important to note that this analysis is based on average performance across a series of experiments. Therefore, to confirm these results, hypothesis testing was conducted to exclude the influence of variance on the main outcomes of the analysis.

4.2. Hipotesis Testing

Four hypotheses were tested using Welch's t-test, as described in the Subsection 2.5 The hypotheses were formulated sequentially based on the results of previously tested hypotheses.

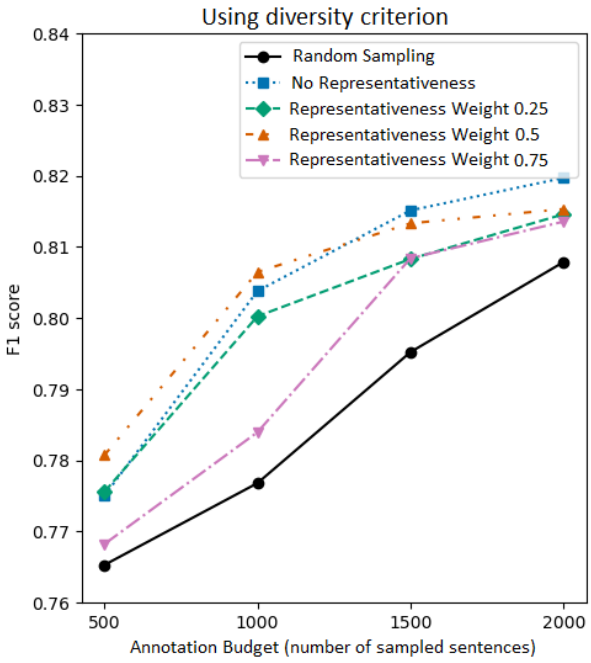

Fig. 5 – Graphs containing the performance of the multi-criteria method including diversity

The first hypothesis tested was whether any of the proposed methods resulted in an improvement compared to random sampling (used as the control in this experiment) in terms of F1-score for low budgets. Low budgets were prioritized in the evaluation since the primary goal of active learning is efficiency with small samples. Thus, the null hypothesis, which we wish to reject, consists of the proposed methods being worse or equivalent to random sampling, as explained below in Equation 7:

$$\begin{cases} H_0 : \mu_{\text{method}} <= \mu_{\text{random}} \\ H_a : \mu_{\text{method}} > \mu_{\text{random}} \end{cases} \tag{7}$$

After calculating the relevant values, Table 2 was generated:

Tab. 2 – Hypothesis Test 1 (Equation 7) - Whether, for a low budget, any method outperformed random sampling

Method	Average F1-Score	Standard Deviation	Var. Coef. %	t-statistic	P-value

volume	0.794829	0.007793	**0.980508**	3.954136	**0.00366**

For a significance level of $\alpha = 0.05$, only Multi-Criteria Active Learning with high representativeness weight or including the diversity factor failed to reject the null hypothesis. For all other methods, superiority over the random method was statistically confirmed.

Thus, as an initial conclusion, the Entity Volume-Oriented Dynamic Selection was chosen as the best method. This choice was not only due to its significant p-value but also because it demonstrated a considerably lower coefficient of variation than the other methods. Furthermore, its low computational complexity solidified its position as the preferred method, confirmed through subsequent tests.

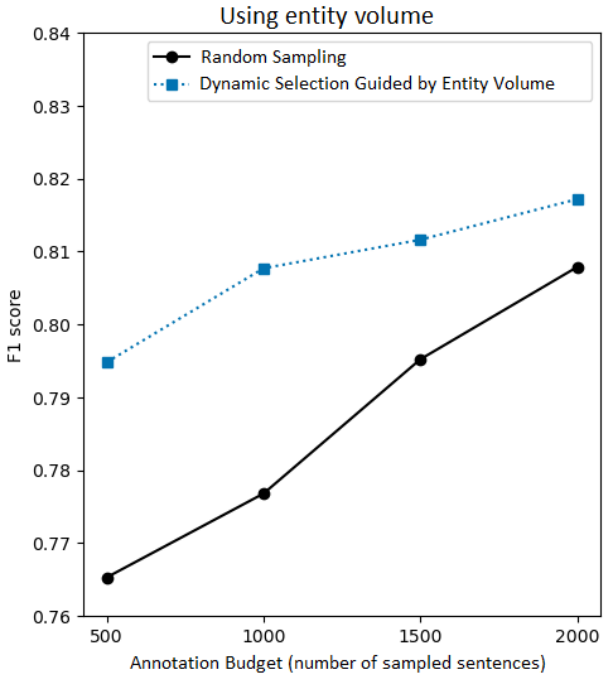

Fig. 6 – Graphs containing the performance of the entity volume method

Next, to confirm the choice of Dynamic Selection Guided by Entity Volume as the best method, the hypothesis that all methods superior to random sampling perform equivalently to this method was tested. If this hypothesis were rejected, it would then be necessary to test whether the other methods are superior to it. Thus, the null hypothesis is equality with respect to the performance of the volume-based method, as shown below in Equation 8:

$$\begin{cases} H_0 : \mu_{\text{volume}} = \mu_{\text{method}} \\ H_a : \mu_{\text{volume}} \neq \mu_{\text{method}} \end{cases} \tag{8}$$

After calculating the relevant values, Table 3 was generated.

info. + repres. (0.75) + diver.	0.768246	0.010041	1.307029	4.67642	**0.00186**
volume	0.794829	0.007793	0.980508	-	-

The analysis showed that distinction in performance could only be confirmed for some methods that were not superior to the control (random sampling). Thus, it was considered reasonable to assume that they are inferior to volume selection.

Consequently, it can be concluded that Dynamic Selection Guided by Entity Volume is not necessarily superior to Multi-Criteria Active Learning, as they demonstrated equivalent performance. However, since both are valid active learning methods for improving models with low budgets (as shown in Test 1), and the volume-

based method has lower computational complexity and a lower variation coefficient, it is considered the better method.

The first graph in Figure 4 exhibited an outlier, suggesting the superiority of Multi-Criteria Active Learning for the case without diversity and with a representativeness weight of 0.25. Therefore, the aim is to reject the hypothesis that this method is inferior or equivalent to others at that budget, as shown below in Equation 9:

$$\begin{cases} H_0 : \mu_{\text{info.+repres. }(0.25)} <= \mu_{\text{method}} \\ H_a : \mu_{\text{info.+repres. }(0.25)} > \mu_{\text{method}} \end{cases} \tag{9}$$

After calculating the relevant values, Table 4 was generated.

Tab. 4 – Hypothesis Test 3 (Equation 9) - Whether, for a budget of 1000 sentences, any method outperformed the multicriteria sampling info. + repres. (0.25)

info. + diver.	0.803814	0.011866	1.476264	1.438642	0.09636
info. + repres. (0.25) + diver.	0.800263	0.018085	2.259836	1.522326	0.08326
info. + repres. (0.5) + diver.	0.806487	0.006227	0.772124	1.316829	0.1223
info. + repres. (0.75) + diver.	0.783971	0.013619	1.737138	3.396902	**0.00506**
volume	0.807713	0.011623	1.439041	1.027128	0.16918

At the chosen significance level ($\alpha = 0.05$), it was not possible to reject the hypothesis that the method was inferior or equivalent to the other candidates for the best method.

Thus, it can be concluded that the observed outlier was merely a result of randomness in the experiment's execution and does not represent any significant phenomenon.

Finally, it was necessary to determine whether the result for low budgets (that the best method was Dynamic Selection Guided by Entity Volume) also held true for high budgets. Thus, we sought to reject the null hypothesis that the methods are inferior or equivalent to the volume method, as shown below in Equation 9:

$$\begin{cases} H_0 : \mu_{\text{method}} <= \mu_{\text{volume}} \\ H_a : \mu_{\text{method}} > \mu_{\text{volume}} \end{cases} \tag{10}$$

After calculating the relevant values, Table 5 was generated.

However, for the chosen significance level ($\alpha = 0.05$), the null hypotheses could not be rejected. Thus, for high budgets, other methods remained inferior or equivalent to the method initially deemed the best: Dynamic Selection Guided by Entity Volume.

5. Conclusion

Through the experiments conducted, it was possible to study the performance of algorithms based on relatively older literature in the field of active learning, which were adapted for use alongside modern large language model-based classifiers. Thus, it was concluded that these algorithms are capable of obtaining, as proposed, samples that are significantly more informative for classifiers than random samples, making them a valuable resource for reducing the cost of corpus annotation.

Additionally, this research's main contribution was the determination that, among the two proposed algorithms, the best one for active learning in legal domain corpora in Brazilian Portuguese, given the configurations studied in this work, is the Dynamic Selection Guided by Entity Volume, as it has lower computational and theoretical complexity and significantly better performance for lower annotation budget values.

Finally, from these results, it is concluded that the predicted volume of named entities is a better predictor of good examples for sample selection, although informativeness and representativeness can also be good predictors, despite the latter being computationally costly.

6. Future Work

To further this research, future work could involve testing the proposed methods with models other than BERT to assess the extent to which the results depend on the underlying model. Additionally, it would be valuable to conduct direct comparisons between these methods and other state-of-the-art approaches. Finally, the methodology identified as the most effective could be applied to develop additional annotated corpora of legal domain documents.

Abstract. The Brazilian judiciary has shown promising interest in applying Natural Language Processing (NLP) techniques to various legal tasks. One such application is classifying legal rulings by the topics of recurring appeals. This study investigates two key strategies for preprocessing legal documents, drawing on insights from legal domain experts: whether using specific sections of the document is more effective for legal ruling classification than analyzing the entire document, and which expressions can be normalized to standardize the document vocabulary. The experimental results indicate that combining normalization preprocessing with the extraction of the judge's manifestation section yields better performance, as measured by the F1 score. Additionally, we demonstrate how the Jaccard similarity index provides valuable insight into the impact of the preprocessing pipeline on the TF-IDF feature extraction method and, by extension, on document representation. This paper underscores the importance of leveraging domain expertise to guide an optimal set of preprocessing operations.

Keywords. Legal document classification, text preprocessing operations, document segmentation and legal terms normalization.
Research paper, DOI: https://doi.org/10.59490/dgo.2025.948

1. Introduction

The Brazilian judiciary has shown a promising interest in developing system and applications that involves Natural Language Processing (NLP) tasks (CNJ, 2024). These efforts aim to process the huge amount of textual data produced by the judiciary and to improve its efficiency and overcome the heavy workload of prosecutions faced by courts across the country.

One relevant problem is the automatic classification of legal rulings by recurring appeal themes - also known as themes of general repercussion (Castro Júnior et al., 2022). These themes are complex legal questions shared by a profuse number of lawsuits and their resolution has the potential to impact thousands or even millions of similar cases. The main goal of this mechanism is to standardize legal agreement on fundamental issues and expedite the analysis of similar legal proceedings.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

While the theme judgment is carried on (e.i. the underlying legal case), the higher courts may order special measures for all related cases in lower courts (e.g. the suspension or pause of all related cases). Hence, the importance of correctly identifying such lawsuits. Traditionally, the court staff must read lengthy documents to determine whether a lawsuit fits a specific theme, a time consuming task. If there is a suspension order for that theme, all the time spent on this task is misused.

This study examines how different preprocessing techniques affect the F1 score metric for the theme classification. The dataset comprises almost 30.000 legal rulings (e.i. Acórdãos) issued by the São Paulo State Court of Justice. We analyze groups of preprocessing operations, one that segment the original document in its constituents sections, and other that standardize common legal expressions to a unique pattern. Then, we compare the effectiveness of such operations by classifying the documents using common Machine Learning algorithms.

Despite the recognized importance of the preprocessing stage, the techniques and operations involved are not standardized or well established (AlMasaud et al., 2024). And the best choice of steps and operations rely heavily on empirical experimentation (HaCohen-Kerner et al., 2020). In others words, there are no common guidelines to aid in selecting the most suitable preprocessing steps.

The language commonly used in the legal domain also has its own uniqueness: a specific vocabulary with precise meanings that may differ from common usage; written documents adhere to a more standardized organizational structure; long and redundant citations of previous similar cases; and the tendency of repeating the same reasoning throughout different documents. Such characteristics should be taken into account during the preprocessing stage.

This paper investigates preprocessing strategies based on expert insights and intuitions: (1) whether using segments of the document can be more effective for its classification rather than the entire content, and (2) whether normalizing specific terms and expressions also could benefit this task. Additionally, this study highlights the importance of incorporating domain knowledge from experts to guide the choices in the preprocessing stage.

Experimental results indicate that expression normalization was the most influential factor in improving classification performance. The document segmentation did not bring the expected performance increasing that we would expected. Still, when combined expression normalization and the extraction of the judge's manifestation segment, these two preprocessing pipelines together tend to outperform the others.

Each preprocessing pipeline produces a modified version of the dataset by altering the content of the original documents. As a result, the Term Frequency–Inverse Document Frequency (TF-IDF) algorithm, which extracts a vocabulary of unique and frequent words from the data, may yield different feature sets depending on the preprocessing applied. To analyze the impact of these pipelines on the feature extraction step, we compute the Jaccard index between the vocabularies sets generated by each pair of TF-IDF models. These pairwise comparisons are then visualized in a heatmap, allowing us to assess whether different preprocessing strategies could lead to distinct textual representations of the same documents.

Therefore, the main contributions of this study are twofold: first, to highlight the importance of incorporating domain expertise in data preparation—specifically, in designing the document preprocessing pipeline; and second, to propose a deeper investigation into feature extraction models, such as TF-IDF, by analyzing their vocabulary sets and visualizing Jaccard index variations through a heatmap. Although still in its early stages, this approach suggests that examining the behavior of feature extraction algorithms may offer valuable insights into selecting the most effective preprocessing operations—potentially reducing the need to exhaustively test all combinations of individual operations directly within classification models.

2. Related works

The preprocessing stage includes operations to clean irrelevant and noisy information for a subsequent task such as text classification. Although it is recognized as a critical step, assessing the impact of different operations is often underestimated (HaCohen-Kerner et al., 2020). The lack of clear guidelines for selecting an optimal set of preprocessing operations, and the need for extensive empirical experimentation may contribute to the limited exploration of different preprocessing pipelines (AlMasaud et al., 2024).

Uysal and Gunal, 2014, HaCohen-Kerner et al., 2020 and Siino et al., 2024 agree that no single combination consistently outperforms the others, and the impact on classification effectiveness highly depends on the problem domain and datasets characteristics. They emphasize the importance of thoroughly testing all possible combinations of preprocessing operations to determine an optimal set for each specific scenario. However, the number of required experiments can increase dramatically as the number of available operations grows.

In the literature, there are no common guidelines to chose the best set of preprocessing operations. For instance, Gôlo et al., 2019 test all combinations of feature extraction techniques and hyperparameter configurations to classify documents from several domains. While Brandão et al., 2023 test a small set of preprocessing pipelines, and Silva et al., 2023 come up with an intricate rule system to find out an optimal set of preprocessing operations. None of them considers to incorporate domain expertise knowledge in the process to choose the best set of preprocessing operations.

Despite the improvement of modern Neural Network Architectures (e.g. Transformers based models) extracting numeric features using Term Frequency - Inverse Document Frequency (TF-IDF) is still a competitive option for lengthy documents, such as in the legal domain. Costa et al., 2023 employed six BERT-derived models for feature extraction in a legal document classification task, and found that the traditional TF-IDF approach produced superior results compared to the BERT-based encoding.

Araújo et al., 2021 compared several supervised machine learning techniques for classifying legal documents. The study used a simple TF-IDF approach for feature extraction. Among the models tested, SVM delivered the best performance with an F1-score of 96.4%. Other methods, including Random Forest, Adaboost, Multilayer Perceptron, and K-Nearest Neighbors, also performed well, each achieving an F1-score above 90%.

Luz de Araujo et al., 2020 proposed the VICTOR dataset for two related tasks: document type classification and theme assignment. Once the dataset originated from scanned documents, they applied regular expressions to infer the text quality and remove OCR tags and special characters. In addition, they applied preprocessing operations such as stemming, stop-word removal, lowercasing, and tokenization of emails, URLs, and legislation citations.

Noguti et al., 2020 compares traditional machine learning approaches with Neural Network Architectures. They conclude that preprocessing operations are more impactful for feature extraction when using the TF-IDF approach rather than the word embedding used by Deep Learning models.

Although Aumiller et al., 2021 explore a more advanced techniques for document segmentation, framing the problem as topical change detection, simpler approaches can be used to test an hypothesis, such as in Feijó and Moreira, 2018 where legal ruling were manually segmented for testing summarization techniques with different parts of the document.

3. Preprocessing pipelines

This section provides a concise overview of the preprocessing pipelines and their respective operations. Firstly, we describe the word-level operations that modify the text itself. Then, we present the structural organization of a legal ruling and briefly discuss how each section was extracted using simple regular expressions patterns. These pipelines are then combined to explore more possibilities of preprocessing pipelines.

3.1. Textual operation

Initially, two sets of operations are conceived: firstly, the cleaned preprocessing pipeline (C) simply removes the document header and footers, line breaks and replaces other white-spaces for a single space character. The normalization pipeline (N) converts text to lowercasing, removes word accentuation, sentence punctuation, and stopwords. The stopword list comprises 416 general Portuguese stopwords, sourced from the spaCy library, and 31 legal terms identified by domain experts. Besides, it removes all words with less than three characters.

And more importantly, it standardizes special words and expressions to a uniform representation employing 156 regular expressions, based on a vocabulary of expressions, abbreviations and acronyms from the Standard Writing Guide of the Superior Court of Justice (Brasil. Superior Tribunal de Justiça, 2016).

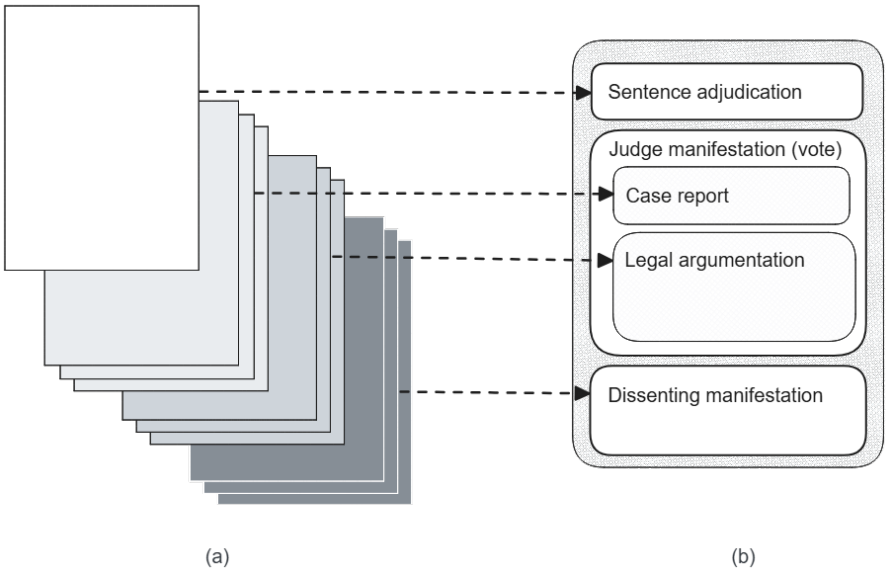

Fig. 1 – While a legal ruling can span several pages, such as illustrated in the left (a), the diagram in the right (b) shows how its internal sections are commonly organized.

For instance, both the name of the Brazilian Superior Court of Justice (e.i. Superior Tribunal de Justiça) and its abbreviation "STJ" are standardized to "`superior_tribunal_justica`." Citations of legislation and other regulatory orders (e.g. Laws, Decrees, Resolutions) are also standardized. In addition, prosecution codes, identification numbers, URLs, email addresses, monetary and percentage values, and other numeric patterns are also regularized.

Initial experiments showed that neither stemming nor lemmatization improved classification performance, so these operations were not included in the study. Furthermore, adapting these techniques to align with the regular expressions used in the normalization pipeline proved to be both complex and potentially counter-productive.

3.2. Document segmentation

In the Brazilian judiciary system, one of the primary roles of higher courts is to serve as appellate bodies, reviewing cases and rulings from lower court jurisdictions. Certain decisions are made by a panel of judges, and the ruling is referred to as an "Acórdão." Typically, the panel of judges is organized into chambers or sections, each composed of at least three members. Moreover, an authoring judge, known as the rapporteur, is appointed to analyze the case, decide on its admission, draft a formal opinion, and recommend the appropriate legal action.

For collegiate decisions, the panel of judges reviews the authoring judge's draft and decides whether to agree with it, aiming to form a majority. In cases of disagreement, the dissenting judge writes a separate opinion, presenting their reasons for disagreeing with the authoring judge's initial position . This dissenting opinion can significantly extend the document's length, as it provides counterarguments for each specific point of disagreement.

Although there is no entirely uniform structure, the legal ruling generally consists of three main parts, as illustrated in Figure 1: the adjudication of the sentence itself, the authoring judge's opinion and, eventually, a dissenting manifestation. The adjudication is found on the first page and contains the decision statement, the judges who participated in the judgment, and the authoring judge responsible for drafting the opinion. This is a more uniform section, which uses standard terms, making it ideal to extract information by applying regular expression.

The authoring judge's formal opinion, also known as vote, includes a summary of the case, references to relevant legislation, citations of previous ruling on similar issues, and suggests a legal action for the case. This

opinion is typically divided into at least two sections: the case report and the legal argumentation (see Figure 1). The case report summarizes information related to the specific case, while the argumentation section cites the legislation and precedent cases that support their decision. For similar cases, the judges tend to repeat the citations of legislation and the previous rulings, leading to documents that are alike to each other.

Legal domain experts suggest common terms and expressions that indicate the transition from one section to another. Hence, regular expressions are able to identify the beginning and the end of each section using this knowledge. Additionally, two strategies help in this process: a sequential section identification, using earlier information to aid the next section detection; and testing a wide list of regular expressions to spot each section.

For example, the authoring judge's name appears as a signature, in the last line of the decision adjudication part (first section) and also in the last line of his draft manifestation marking the beginning and the end of the judge manifestation. The first part of his manifestation is the case report, and common expressions mark the end of this section and the beginning of the legal argumentation. Notwithstanding, the authoring judge's name may differ along the signature lines, sometimes including an additional middle name or abbreviating it. In these circumstances it is necessary to programmatically adapt the regular expressions to accommodate possible variances.

It is worth mentioning the iterative refinement of each regular expression pattern. Whenever possible, two or more patterns are merged into a more powerful and efficient one. Although it shrinks the quantity of rules applied, it also increases its complexity for debugging purposes. Moreover, application of the rules goes from the more generically, that handle more expression variations, to the more restricting ones, aiming to speed up the verification procedure.

One may recognize that detecting one section depends on the success of the previous one. For instance, locating the argumentation section depends on successfully identifying the case report summary. If some segmentation is unsuccessful, we use the last identified section until we default to the entire document. For example, if we try to identify the argumentation section and it fails, we return the content of the judge's manifestation (summary case report plus the argumentation).

The segmentation strategy originates the datasets named Legal Argumentation (LA) corresponding only to the juridical argumentation, and Judge Manifestation (JM) that also includes the case report section. Both versions exclude the dissenting vote section. Furthermore, these two dataset went through the normalization preprocessing operations, obtaining its versions with expressions regularized, and indicated by signs $LA+N$ and $JM+N$, respectively.

The downside of this based-rule approach is that the regular expressions are specific to our collection of documents. Although some writing patterns are similar across judges and courts, adapting to other contexts might require additional effort. However, we use this procedure only to test the hypothesis whether using segments of the documents might be more efficient on legal ruling classification.

4. Experimental setup

In this study we evaluated at least seven machine learning algorithms across six versions of the dataset, each corresponding to a different preprocessing pipeline. The experiments were conducted in a Google Colab Pro environment. In the following we detail the dataset characteristics, the learning algorithms, and the experiment setup in detail.

4.1. The dataset

The dataset, developed under a broader research project funded by the São Paulo State Court of Justice, consists of 33,016 legal rulings considering Special Appeals in the Private and Consumer Law domains. Due to the project guidelines on sensitive information disclosure, we are not able to make the dataset publicly available.

A legal ruling might entail multiple themes, configuring a multiclass classification task. Table 1 shows the six themes of interest in this study, its definition and the number of positive instances for each class. Since we use algorithms that induce binary classification, we divided the original task into six binary classification tasks. This decision corresponds to the one-versus-all strategy, which is a feasible practice in such circumstances.

Tab. 1 – Positive class instances for each label in absolute values. Each theme is represented by a alphanumeric code. The letter S in some labels indicate whether the theme originates at STJ Brazilian Court, rather than the STF Court.

Label Code	Theme Definition	Positive Instances
S0929	Discussion on the conditions under which the double refund stipulated in Article 42 of the Consumer Defense Code (CDC) applies.	2479
S1101	Final date for the application of compensatory interest in collective and individual lawsuits seeking the restitution of inflationary purges in savings accounts.	2004
1011	Controversy regarding the legal interest of Caixa Econômica Federal in joining as a party or third-party intervenor in lawsuits involving housing loan insurance under the Housing Finance System, and, consequently, the jurisdiction of the Federal Court to process and adjudicate such cases.	1038
S1039	Establishment of the starting date for the prescription period of indemnity claims against insurers in contracts, whether active or terminated, within the Housing Finance System.	830
S1016	Validity of a contractual clause in a collective health plan that provides for adjustments based on age brackets; and burden of proof regarding the actuarial basis for the adjustment.	669
S0958	Validity of the charges in banking contracts for services provided by third parties, contract registration, and/or asset appraisal.	509

4.2. Feature extraction

Despite the improvement of modern Neural Network architectures and word embedding representation, Term Frequency - Inverse Document Frequency (TF-IDF) is still a competitive feature extraction option for lengthy document classification, as in the case of the legal domain. The scikit-learn implementation of the TF-IDF algorithms was employed. Previous experiments have shown a vocabulary size of 3,000 tokens and the use of unigrams and bigrams yields better results.

The TF-IDF algorithm selects the 3,000 tokens most frequent in corpus and computes the document frequency for each token, e.i. how many documents that token appear in the corpus. Then it calculates the term frequency of the token in each document and weighted this value by the inverse of the document frequency. Hence a document is encoded in a vector with dimension equal to the number of tokens in the vocabulary. These vector values can also be normalized by the sum of absolute values (l_1 normalization) or by the sum of squares of its elements (l_2 normalization) which was the selected option.

4.3. Classification algorithms

To evaluate the efficiency of the preprocessing pipelines, we use standard classification algorithms provided by the scikit-learn library Pedregosa et al., 2011: Decision Tree classifier (DT), Logistic Regression (LR), Support Vector Machine (SVM), Stochastic Gradient Descent (SGD), Random Forest (RF), and Extra Trees Classifier (ET). We also employed the Extreme Gradient Boosting (XGB) algorithm from the XGBoost library. We use the default parameters for all classifiers as recommended by the respective libraries.

We also employ cross-validation with five folds, using the stratified variation, and collect the precision, recall and F1-score for the test set. However, Tables 2 and 3 reports only the F1-score for conciseness. Therefore, seven machine learning algorithms were tested across six preprocessing versions of the same dataset of legal documents, for each of the six themes (or labels) considered in this study.

5. Results and discussion

Tables 2 and 3 show the average F1 scores obtained from the experiments. Table 2 contains the results solely from the document segmentation pipeline experiments, while Table 3 displays the results from the normalized

Tab. 2 – Average F1-score considering the document segmentation experiments. The preprocessing pipelines are: the cleaned text (C), legal argumentation only (LA), and all the judge manifestation (JM). The classification algorithms refer to Decision Trees (DT), Logistic Regression (LR), Support Vector Machine (SVM), Stochastic Gradient Descent (SGD), Random Forest Classifier (RF), Extra Trees Classifier (ET), and Extreme Gradient Boosting (XGB).

	LA	0.6662	0.7219	0.7828	0.7436	0.6176	0.6403	**0.7900**
	JM	0.6828	0.7293	0.7825	0.7415	0.6252	0.6386	**0.7946**

version of the datasets. The bold values indicate the highest value for each row, i.e. the highest value among the classifiers for a single pipeline. The shaded values indicate the highest value for a classifier across different pipelines (i.e. the highest value in the column) specifically for each label. Values are considered a tie if the first two decimal digits are equal–hence, all similar values are highlighted.

Table 2 suggests that there is no clear pattern indicating the best document segmentation pipeline for all classes. Nevertheless, the LA (Legal Argumentation) and JM (Judge Manifestation) preprocessing pipelines tend to perform better than the C (Cleaned) preprocessing, which considers the entire document.

The results in Table 3 indicate that the normalized version of the documents outperforms the non-normalized ones. Incorporating domain knowledge through standardized expressions is a promising approach for preprocessing legal documents. In this context, the JM (Judge Manifestation) preprocessing method performs better than the others, particularly for underrepresented classes such as 1011, S1039, S1016, and S0958.

For both cases (Table 2 and 3) the Extreme Gradient Boosting (XGB) achieved the best results in most scenarios (bolded values) followed by the SVM classifier. However, the variation between the best and worst results for the XGB algorithm is small, regardless of the preprocessing pipeline used. This suggests that XGB is not significantly affected by changes introduced through preprocessing.

The extraction of the legal argumentation segment (LA pipeline), although its high complexity, did not produce superior results than the JM pipeline. In other words, the judge's manifestation segment (i.e. removing the adjudication page and the dissenting vote declaration, when present) is preferable than the LA pipeline due to its lower complexity and cost. Additionally, associating the JM preprocessing with the expression normalization led to even better results, as shown in Table 3.

Essentially the results suggest that not all preprocessing pipeline produces significant differences on document representation. One way to visualize this situation is to plot a 2-dimension or 3-dimension scatter plot representing the embedding space, using a dimensionality reduction method such as Principal Component Analysis (PCA) or t-distributed Stochastic Neighbor Embedding (t-SNE)(Cao & Cui, 2016). However, this representation produces one plot for each dataset version that is difficult to compare them directly.

Tab. 3 – Average F1-score considering the same preprocessing before, plus the normalization preprocessing. Hence, the preprocessing pipelines are: cleaned content normalized (C+N), legal argumentation normalized (LA + N), and the judge manifestation normalzied (JM + N). The classification algorithms refer to Decision Trees (DT), Logistic Regression (LR), Support Vector Machine (SVM), Stochastic Gradient Descent (SGD), Random Forest (RF), Extra Trees Classifier (ET), and Extreme Gradient Boosting (XGB).

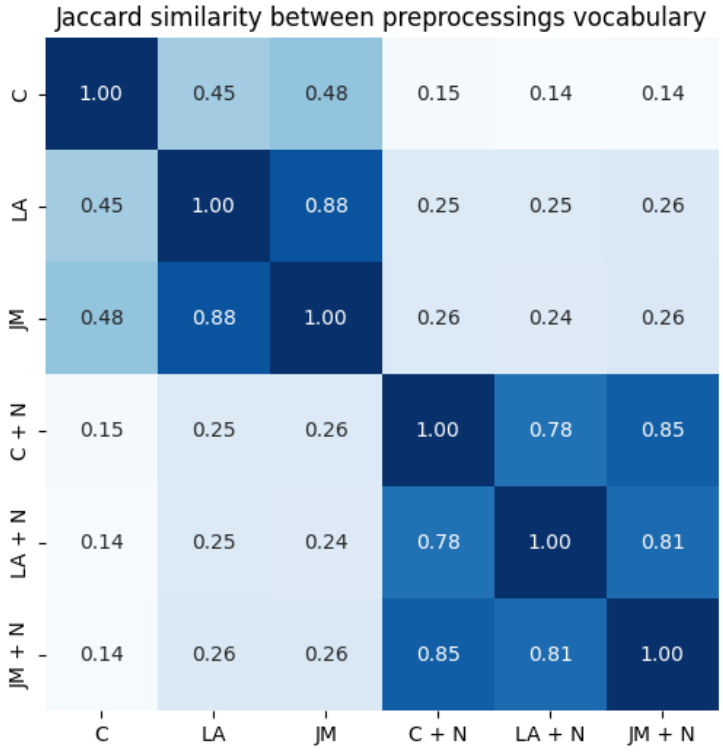

Fig. 2 – Jaccard index heatmap comparing vocabulary overlap across all pairs of preprocessing pipelines based on the TF-IDF algorithm.

Therefore, we propose analyzing the Jaccard similarity index between the vocabulary sets generated by the TF-IDF algorithm for each preprocessing pipeline. This index is calculated as the ratio of the number of elements in the intersection to the number of elements in the union of two distinct sets. Although the Jaccard index does not account for word frequency, it still offers valuable insights into how preprocessing operations influence the vocabulary computed by the TF-IDF algorithm and, consequently, the document representation.

The results are presented in Figure 2. The non-normalized preprocessing group (C, LA, and JM) and their

normalized counterparts (C+N, LA+N, and JM+N) exhibit high similarity within their respective groups but differ significantly from each other. This pattern aligns with the findings in Tables 2 and 3, where the F1-score does not vary as much within each table.

6. Conclusion

In this study, we examined the impact of various preprocessing pipelines on the classification of legal documents, focusing on judicial decisions in the Brazilian legal system. The normalization of legal expressions consistently enhanced classification performance, demonstrating the importance of tailored preprocessing in legal domain. Segmenting documents considering its constituent sections, particularly the judge's manifestation pipeline, enhance the classification performance, yielding better results than using the full text with only basic cleansing operations.

Moreover, we emphasize the importance of examining how preprocessing operations influence feature extraction models and the resulting feature sets. Although the literature provides no clear guidelines for selecting the most appropriate preprocessing strategies, analyzing their impact on feature extraction algorithms (e.g. TF-IDF) can offer valuable insights into this decision-making process. To illustrate this point, we propose investigating the vocabulary sets generated by each preprocessing pipeline by calculating the pairwise Jaccard index over the outputs of the feature extraction model. This type of analysis can be further extended through alternative visualizations and techniques, which we consider promising directions for future work.

Submitted: 31 January 2025, Revised: 26 March 2025, Accepted: 21 April 2025, Published: 23 May 2025

Abstract. An efficient test process can detect failures earlier in software development, contributing to the quality of software produced by governmental entities and bringing the potential to improve government service delivery. Due to the high cost and the reduced resources available, the automation of the test activities plays a strategic role in improving testing efficiency. Designing test cases from user stories is a common approach to assessing the quality of a system under testing. This paper reports on the research, implementation, and evaluation of a tool that automatically generates system test designs from user stories with the support of Generative Pre-trained Transformer 4 (GPT-4) in the context of a public sector organization. The tool has been conceived to match the needs and particularities of the organization's test process. Such a tool reads user stories from the Redmine tool, interacts with GPT-4 using a prompt that outputs test cases, and stores the automatically designed tests in the Squash TM test management tool. Organization test analysts stated that the tool produces good quality tests and reduces the effort to create tests. As a consequence, analysts can put more energy into other activities related to testing. Moreover, comparing the tests designed manually by test analysts with the tests designed by the tool shows that both have the same functional coverage. The paper discusses the impacts of the approach in the process, limitations, and related and future work.

Keywords. automated test design, LLM, user story, system test cases

1. Introduction

Software solutions are an essential part of the services provided by public sector organizations. In such a context, software testing (Myers & Sandler, 2004) is necessary to assess the quality of software products and reduce operational costs due to software failures. Failures detected later cost much more to be corrected than

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

those detected earlier (Kushwaha & Misra, 2008). Improving the quality of software produced by governmental entities has the potential to improve government service delivery. The cost of software testing may be higher than 50% of the total cost of software development (Myers & Sandler, 2004). Due to such high costs and reduced testing resources, the automation of test activities plays a strategic role in improving testing efficiency. Surveys (Garousi & Varma, 2010; Ng et al., 2004) conducted in the public sector show that automation of test activities is a demand to make the testing process more efficient. Moreover, testing methodologies (Nomura et al., 2013; Sivaji et al., 2011) and quality models (Kushwaha & Misra, 2008; S Al- Tarawneh & Al-Tarawneh, 2022) have been proposed to improve the effectiveness of testing in the public sector. Propositions recommend the use of automation as a tool to improve the test process.

Test cases are vital in testing (Myers & Sandler, 2004); each test is an experiment that defines the inputs provided during test execution and the expected outputs produced by the System Under Testing (SUT). The demand for tests increases proportionally to the size of the application. Test design is a critical activity in software testing that focuses on creating test cases; it is not trivial and demands specialized skills. It is present in almost all testing levels and testing types (Sommerville, 2007). A well-designed test case increases the chance of finding important issues in the system's behavior. The automation of test design is a relevant approach to improving test effectiveness. System testing is a testing level where the test cases mimic the final test analyst interaction with the SUT. At such a level, tests are created based on the system's specifications (black box approach). Thus, system testing design requires interpreting existing documentation that functions as the test basis. Notably, user stories (Sommerville, 2007) are a fundamental component of agile software development; they are lightweight for capturing and managing requirements. User stories are a standard test basis for test design in agile processes.

The context of the current research is the software development process of a public sector organization that works with auditing and accountability, namely Tribunal de Contas do Estado de Pernambuco (TCE-PE)[1]. Such an organization produces web systems that support its services to the population. In the TCE's software development process, test analysts receive user stories as the main input for the design of system-level test cases that are executed to validate the correct behavior of the produced software. Furthermore, the organization lacks sufficient resources to design and execute tests for its systems. The demand for testing is greater than the number of existing human resources (Lins et al., 2023). The partial automation of test design would reduce the effort in the design so that test analysts would put more effort into running the tests and detecting defects to be corrected as early as possible.

Previous works have explored test generation from user stories for producing system tests (Chinnaswamy et al., 2024; Granda et al., 2021; Mollah & van den Bos, 2023; Pallavi Pandit, 2015). However, the existing solutions differ in the format for the user stories, the format and the purpose of the produced tests, and the approach used for test generation. Moreover, related work has not been motivated or evaluated in the context of a public organization, as in the current work.

The current paper addresses three research questions.

R1 How to build a tool that reads user stories and automatically designs system test cases?
R2 How do the test cases designed by the tool compare to the tests designed by the test analysts?
R3 What are the test analysts' perceptions of the tool and the automatically designed test cases?

To answer the first question, we created a prototype for a tool that uses an LLM to automate the design of system tests for manual execution, considering the tools used for testing the software produced by the public organization of this study. The proposed prototype interacts with ("GPT-4", 2025) to obtain system tests by inputting user stories. The interaction uses a prompt following the few-shot technique crafted with examples of user stories and the respective test cases in the desired format; then, original test cases are yielded by the LLM based on user stories that have not been provided as examples. Such a tool has been implemented in Python and provides a command line interface that allows test analysts to generate system test designs from user stories that are read from the Redmine tool, and the automatically designed tests are stored in the Squash TM (*Squash TM*, 2025) test management tool. To answer the second question, we compared the tool-designed tests with the existing ones with respect to the number of tests, steps, and functional coverage. It could be verified that the functional coverage of the tests designed by the tool is similar to that designed by the analysts. Moreover, the number of tests and steps is very similar to those created by the analysts. To answer

[1] https://www.tcepe.tc.br/internet/

the third question, we created an anonymous questionnaire to collect the perceptions of the test analysts and also conducted a meeting to collect complementary feedback for the tool. After using the tool to support test design in their habitual process and environment for about a month, test analysts stated the tool reduced the overall effort for test design by 60% significantly improving efficiency. It also simplifies the use of Squash TM by automating mechanical tasks, which are often a significant obstacle for analysts, as noted in their feedback. The feedback also included points for improving the tool.

The remainder of this paper is organized as follows. The next section introduces the organizational context of this work and the main concepts that outline this work. Section 3 overviews the steps of the research method. It describes our eight-step process followed in this research. Subsequently, Section 4 details the tool's architecture and the tool workflow from the point of view of the test analyst. Afterward, Section 5 presents details on the evaluation and key findings supported by collected data. Then, Section 6 discusses the research questions in light of the evaluation results and their implications. Finally, Section 7 summarizes contributions, presents related work, and discusses future work.

2. Context and conceptual background

This section overviews the relevant portion of the testing process of the organization in the public sector that contextualizes this research. In such a process, the project is organized as sprints, as shown in (Augustine, 2005). On each sprint, requirement analysts create user stories and store them in Redmine. Then, developers and test analysts use the stories as the basis for coding the application and for designing test cases using Squash TM, respectively. Moreover, Squash TM is used by test analysts to create an execution plan with a list of tests to be executed. After the developers release a version for testing, the test analysts execute the tests following the execution plan and keep a record of the status of each individual test. Failed tests are reported to the developers to fix the software. Failing tests are re-executed after the fixes. After releasing a software version that passes the tests, the product owner validates the new version, which can lead to new bugs and fixes. After successive interactions, the software has all its features implemented and can be deployed for the end users of the public organization. In what follows, we show the format for user stories and test cases and the tools used to manipulate these artifacts.

This paper does not exhibit internal artifacts of the TCE-PE software development process for confidentiality reasons. The user story and test cases presented in this section follow the format of the real artifacts; however, they do not relate to a real system.

2.1. User stories and Redmine

A user story (US) facilitates communication between technical teams and end test analysts, ensuring that the development process remains user-centric and aligned with stakeholder needs. The Redmine tool (*Redmine*, 2006) is an open-source project management and issue-tracking tool that supports agile workflows and efficiently organizes sprints and user stories. Also in Redmine, it is possible to define user stories and link them to sprints, creating an organized flow.

Figure 1 shows a sample US, a simplified version of the format used in the public organization that contains the relevant fields for test case design. The US in Figure 1 specifies the behavior for the system login page. Each US is identified by a unique ID, in the sample, the ID equals 00001. This information is relevant for relating tests to the respective source US. The US title (displayed in the first line of the figure offers a quick reference to the purpose of the US, helping to identify the area of functionality the tests will cover. The title is preceded by the `PROJ` prefix, which is a sample acronym for the project that the US belongs to. The description provides context about the user's goal and the functionality's purpose. The scenarios field outlines the flows of the SUT behavior. In the sample US, there are two scenarios, the first scenario evaluates the system's ability to authenticate a registered user with valid credentials, ensuring successful login and redirection to the homepage. The second scenario tests the system's response to invalid credentials, verifying that an appropriate error message is displayed, preventing unauthorized access while providing clear user feedback. Acceptance criteria specify the expected outcomes and requirements that must be met; in the sample, there are four. A test analyst must design test cases to verify the condition described in each criterion of a US.

User Story #00001

PROJ - *As a registered user, I want to be able to log in to the platform to access my profile and exclusive content.*

Description
This feature enables registered users to securely log into the platform, providing access to personalized content and their profiles. If users enter incorrect credentials, a clear error message is displayed, and if they forget their password, a reset option is available.

Scenarios

1. **Successful login with valid credentials:**
   - Given a registered user with valid credentials, when the user enters their correct username and password and clicks the login button, then the user is successfully authenticated and redirected to the platform's homepage, where exclusive content is accessible.
2. **Login with invalid credentials:**
   - Given a registered user attempts to log into the platform, when the user enters an incorrect username or password and clicks the login button, then a clear error message is displayed, indicating that the login information is incorrect.

Acceptance Criteria
a) As a registered user, I want secure access to the platform to view my profile and personalized content.
b) I want to enter my username and password to log into my account.
c) After successfully logging in, I want to be redirected to the platform's homepage, where I can begin exploring the exclusive content available to me.
d) If I enter invalid credentials, I expect to receive a clear error message indicating that my login information is incorrect.

Fig. 1 – User Story

2.2. Test cases and Squash TM

A classical format for a test case design for system testing (Sommerville, 2007) specifies preconditions (pre-requisites) and execution steps. Preconditions specify the necessary conditions (setup actions) to start the test. Each step contains the inputs provided to the SUT and the expected outcomes. The execution of a test case is an experiment to verify that the SUT meets its specification. If some step fails during the execution, we say the test fails and the execution evidences a defect in the SUT. A defect is a deviation from the expected behavior described in the US. If no step fails, the SUT passes the test.

Key requisites for a good test case include clarity, repeatability, and traceability to user stories. A set of test cases covers the functionality of a set of user stories if there is at least one test case to verify the scenarios and criteria specified in the stories. Figures 2 display tests in the interface of Squash TM that cover the US shown in Figure 1.

Figure 2 presents the key fields of tests in Squash TM, with non-essential fields omitted. At the top of the figure, the title field is highlighted in green. The title should clearly identify a test. Each test has a unique ID that appears in the Figure 2 as `CT-PROJ-2`. This tag is the composition of the prefix `CT` with the project acronym (in the sample `PROJ`) and a number. The test status and prerequisites are displayed below the title; they are followed by the actions (inputs) and the expected results. The test analyst is responsible for verifying that these actions comprehensively cover the scenarios and meet the acceptance criteria established in the related US.

In Squash TM, test cases can be organized in folders. A helpful structure is to create a folder of test cases for each Sprint. There is also the Requirement field, which includes a reference to the user stories that are used as the basis for writing the test case. This field allows linking tests to user stories, ensuring traceability.

3. Overview of the research method

This research seeks to answer the three research questions listed in the introduction. For this purpose, it followed eight steps.

1. Selection of existing user stories and test cases to be used as references.

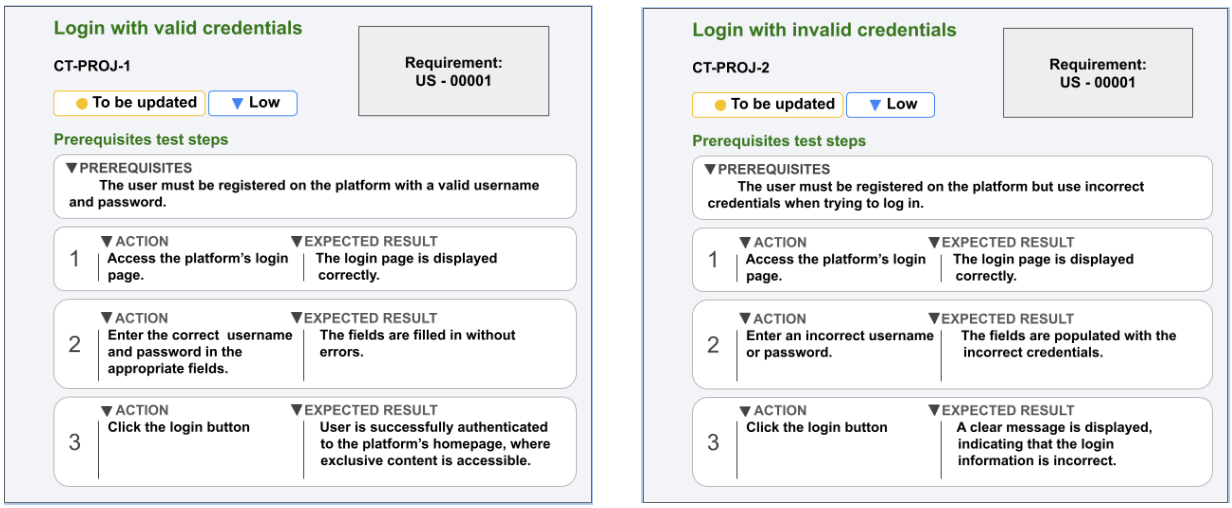

Fig. 2 – Tests created by the US2Test Tool for US 00001

2. Implementing the tool US2Test to automatically design tests from user stories using LLM.
3. Comparing the test cases designed by the tool to the existing test cases.
4. Sharing comparison results with test analysts to collect feedback about the automatically designed tests.
5. Distributing US2Test to the test analysts.
6. Collecting feedback from test analysts using an anonymous survey.
7. Scheduling a meeting with the test analysts to collect direct feedback.
8. Analysis of the results.

We explain the above step. First, the organization's quality assurance team provided reference artifacts consisting of well-designed test cases created to cover a predefined set of user stories. The reference artifacts follow the organization patterns and guidelines for having good-quality user stories and test cases. Such artifacts have been used in previous versions of software developed by the organization. The second step was to develop the US2Test tool that uses LLM to generate tests from the US. The implemented tool interacts with GPT-4 using OpenAI API to design test cases. The third step focused on using the tool to design tests automatically and compared this suite to the test suite designed by test analysts (provided in the first step).

The fourth step consisted of sharing the comparison results with analysts to gather their impressions before they start using the tool. Based on the feedback received, we could enhance the tool and distribute the binaries to the test analysts (fifth step) for their daily use. In this way, they could design tests using the tool by themselves. The sixth and seventh steps involved collecting further feedback after the analysts had actively used the tool. Initially, feedback was gathered anonymously, and the forms were distributed approximately one month after the test analysts gained access to the tool. About two months after accessing the tool, a meeting was scheduled to collect more direct and detailed insights. Finally, we analyzed all the data and started writing this paper.

4. Tool for automatic test design using LLM

The automatic test generation approach introduced in this section is tailored for use in the test process of TCE-PE (presented in Section 2). Therefore, the development follows the particularities of the organization's testing process. Figure 3 illustrates the proposed test generation approach implemented by a tool called US2Test. In the figure left-hand side (in cyan) are the primary inputs for test generation: examples of user stories stored in Redmine (`Example US (Redmine)`) with their respective test case (`Example US (Redmine)`) and the user stories that we want to generate new tests (`Input user stories (Redmine)`). Examples are retrieved from Redmine and Squash TM using the APIs for such tools. User stories and tests follow the format introduced in Section 2 (refer to Figures 1 and 2). The inputs are translated into JavaScript Object Notation (JSON) format (blue color) and processed by a Python script that creates a prompt that is the input for the GPT-4 API. The GPT-4 model processes the prompt and yields a set of test cases encoded in JSON format for the desired user stories. The set of test cases is then pushed to the appropriate location in the API of the Squash TM tool.

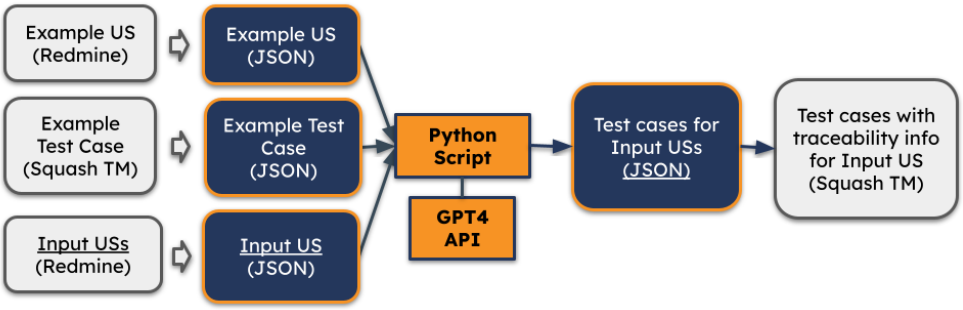

Fig. 3 – Workflow for the US2Test tool

The tool performs (Bahrami et al., 2023) to guarantee that the automatically designed test cases follow the classical test case format, which is one of the formats accepted by the Squash TM tool. Moreover, by providing examples of user stories and test cases, we help the model understand the match between the user stories and test cases so that tests designed for the input user stories follow a predefined style for the tests.

Listing 1 illustrates the prompt used in our approach to generate tests. This prompt follows the RTF (Role Task Format) format, which instructs the prompt on its role, the task it will perform, the rules it will follow, the format for the inputs, and the format for the expected response. The prompt specifies rules to maintain consistency, such as ensuring that each test step has a corresponding expected result. Additionally, each test case must have preconditions, and only the JSON with the test cases should be returned without extra information. The placeholders `<EXAMPLE USER STORIES>`, `<EXAMPLE TEST CASES>`, and `<USER STORIES>` represent, respectively, the sample user stories, test cases for the sample user stories, and the stories we want to generate new tests. Such placeholders are replaced by JSON objects representing content retrieved from Redmine and Squash TM. Likewise, the prompt instructs the model to use specific black-box testing techniques, such as Equivalence Class and Boundary Analysis (Myers & Sandler, 2004). These techniques are employed to design tests that verify significant cases and edge cases for the scenarios described in the input user stories.

Listing 1 – Few-shot Prompt

```
You will act as a test case creator. You will receive a user story in JSON format and should
    return enough test cases to cover the user story, considering the use of black-box techniques
     such as equivalence class and boundary values. The result must be returned in JSON format (
    RFC 8259). Some rules: For each test step, there must be an expected result; The number of
    steps and expected results must be the same, so that an expected result is linked to a step;
    Steps that consist of verifying something must be in the expected result field; Each test
    case must contain preconditions; You should return only the JSON with the Automatically
    designed test cases, without any additional information.
Here is an example of a user story: <EXAMPLE USER STORIES>
The test cases for this user story are: <EXAMPLE TEST CASES>
Generate test cases for the following use stories: <USER STORIES>
```

The code snippets in Listings 2 and 3 are JSON objects that represent the US and the test cases introduced in Section 2.1. The snippets are abbreviated for conciseness. The placeholders `OTHER CRITERIA`, `OTHER SCENARIO`, and `SECOND TEST HERE` indicate the points that have been omitted. The omitted criteria require successful login, redirection upon authentication, and access denial for incorrect credentials. The concealed scenario specifically examines failed login attempts, while the hidden test verifies that access is denied following this scenario.

     }, { ~SECOND TEST HERE~ } ] }
```

The tool stores generated tests in a particular folder of Squash TM as exhibited in Figure 4. The tests in this figure represent the tests depicted in Figure 2.

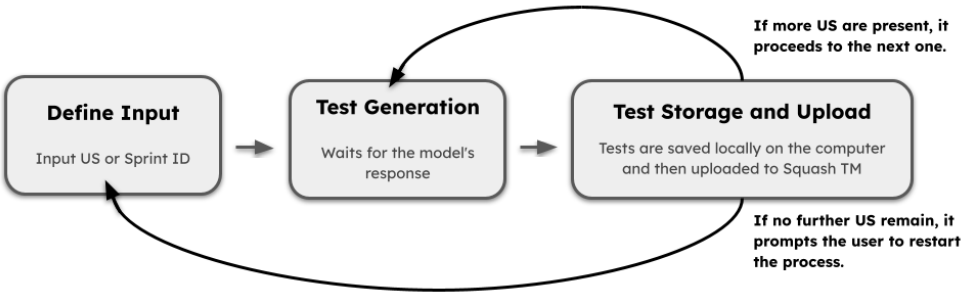

Fig. 4 – Test analyst workflow

We explain the steps to use the tool. The tool´s command line interface follows a structured process, as outlined in Figure 4. Before starting to use the tool, the test analyst needs to include the credentials for Redmine and Squash TM in a configuration file. As the first step, the test analyst needs to define the inputs for the test design. It can choose between generating tests from individual user stories or sprints. Using the first option, the test analyst can manually input one or more IDs for user stories. In the second option, the test analyst can provide a sprint ID, and the tool will yield tests for all user stories associated with the sprint.

After the test analyst defines the inputs, the tool initiates the test generation process for each US. This step is typically the most time-consuming, as it relies on the LLM. Errors can occur during the generation, even if the inputs respect all formatting rules. The model generates malformed outputs, so the tool needs to verify

whether the tests are syntactically valid. If errors are detected, the tool automatically initiates a new interaction with the model to redesign the tests, with up to five attempts.

Once the test generation has finished successfully, the test cases are locally stored on the computer and then uploaded to Squash TM. For the upload, the test analyst should provide the target folder in Squash TM (mandatory) and, optionally, the project acronym (default value is PROJ if not specified) and the test number (default value is one if not provided).

Finally, after processing one US, the tool checks if there are more user stories to process. If so, it proceeds to the next one and starts a new iteration for preparing new tests. Otherwise, it restarts the process by asking the test analyst to provide new inputs.

5. Evaluation

This section presents the execution of the evaluation as well as its results in the public sector organization, which is the context of this work. It further details the third to the seventh steps of the research method presented in Section 3.

5.1. Evaluating the tests designed by the tool

A very relevant part of the evaluation is to compare the test cases designed by the LLM to the existing test cases and to collect feedback for the automatically designed tests from the test analysts. This section reports on both parts.

The comparison used as a reference the set of seven US provided by the quality assurance team (see Section 3). Such a set was split into two disjoint subsets: a set with three user stories (and its respective test cases) to be used as examples for the prompt (see Section 4), and the second set containing four user stories used as input to create new tests using the tool US2Test. The tests designed by the tool have been compared to those designed by the test analysts.

For each reference US, we collected two measures and one metric to compare tests produced by the tool and those created by the analysts.

Number of Tests Records the total number of tests designed for a particular US. The number of tests indicates the number of separate test cases developed to verify the user stories. It reflects the test suite's depth to cover different scenarios through distinct tests. A very small number of tests would increase the risks of potential defects not being detected (Myers & Sandler, 2004). On the other hand, many tests are not welcome since they cannot be feasible for test execution due to resource availability.

Number of Steps This measure represents the sum of the number of steps of the tests designed for a particular US. The number of steps in each test case provides insight into the level of detail and granularity of the actions required to carry out each test. This measures the complexity and thoroughness of each test case, reflecting how procedural actions are broken down.

Test suite coverage Stands for the coverage of a test suite. Let TS be the sum of the number of scenarios and acceptance criteria for a particular US, and CS represent the number of test scenarios covered by a test suite created for the same US. This metric is obtained by the expression $CS/TS * 100$ that records the percentage of scenarios and criteria of a given US that are addressed by at least one test in the test suite. This metric is essential to evaluate the quality of a test suite. Complete (100%) or near-complete coverage ensures that the test cases address all functional paths and requirements, minimizing the risk of missed defects.

Table 1 shows the measures for the tests designed by the analysts (MDT — Manually Designed Tests) and for those designed using the tool (ADT — Automatically Designed Tests). The table consists of four columns: US, Manually designed tests, Automatically designed tests, and Difference. The US column represents the ID of each US used in the evaluation. The columns Manually designed tests and Automatically designed tests refer to tests created by analysts and the tool, and the Difference column refers to the difference in the metrics between MDT and ADT. The last three columns are further divided into two sub-columns: Test and Steps. These sub-columns refer to the total number of tests and steps.

US	Manually designed tests		Automatically designed test		Difference	
	Tests	Steps	Tests	Steps	Tests	Steps
1	2	4	2	6	0	2
2	2	4	4	16	2	12
3	2	2	2	7	0	5
4	2	2	2	6	0	4
Sum	8	12	10	35	2	23

Tab. 1 – Tests comparison table

Table 1 shows differences in the number of tests and steps in MDT and ADT. The difference shows that while the test quantity typically remains consistent between the two methods, the number of steps is often higher in the ADT. Despite this difference, all tests and steps in ADT are related to some tests and steps in MDT. We report the main differences noted between the number of test steps in ADT and MDT.

1. Tests in MDT benefit from the analyst's knowledge of the system's user interface (UI), enabling the definition of optimized sequences of actions to execute. In contrast, tests in ADT are solely based on the US content since the prompt is not fed with UI information; thus, designed tests occasionally include intermediate navigation steps the LLM deems necessary to reach the appropriate screen.
2. Tests in ADT systematically include a final step to confirm the save operation to persist changes. While save actions are left implicit in the analyst-created tests.

Similar observations can explain the difference in the number of tests in ADT and MDT for US 2. The first suite contains four tests, and the second two. Putting the tests of both suites side by side, we could observe that the four tests in the first suite, if merged, would yield the two tests in MDT. Such tests could be merged since they can be executed on the same application page. The model does not have information about the UI, and created independent tests that could form a unique test to be executed on the same application page.

These differences highlight how the LLM prioritizes a detailed and explicit description of each action, even at the cost of increasing the number of steps. This approach contrasts with the optimized methodology adopted by analysts, who leverage system knowledge to streamline the test execution process.

The coverage metric is not included in Table 1 since MDT and ADT achieved 100% coverage for each US listed in the table. The collection of coverage was conducted by one of the authors of this paper, who looked for each criterion and scenario in each US and looked for the tests in the suite to find if some steps were referring to the criterion and scenario. This leads to the calculation of 100% coverage of the user stories by ADT and MDT. This means both test suites have completely covered the input user stories used for designing the tests. Consequently, both test suites demonstrate adherence to the acceptance criteria and defined scenarios for each US.

In the meeting to collect feedback with the test analysts (refer to step four in Section 3), despite the differences noted in the number of tests and steps, the analysts considered the tests in ADT as "good tests", since they are coherent to user stories, are easy to follow and have a clear language. Test analysts reported being motivated to use the tool in their daily activities to better assess its functionality and the quality of the generated test cases.

Despite not interacting directly with the system's interface, the approach proved highly effective, accurately executing and validating actions, including screen interactions.

5.2. Collecting survey data

As part of our research method, an evaluation was conducted through an anonymous survey answered by analysts who used the tool US2Test. The survey included questions to assess the tool's usability, effectiveness, and impact on their workflow. Additionally, it has questions to collect the perception of the test cases designed by the tool. The questions in the survey are:

Q1 Does the US2Test tool have any impact on the efficiency of your daily work?

Q2 How much do you consider the tool facilitates the manual test creation process?
Q3 How much do you consider the tool facilitates the process of sending to Squash TM?
Q4 List points you liked and disliked about the tool.
Q5 Are the automatically designed tests clear and easy to understand?
Q6 The automatically designed tests adequately cover the user story scenarios?
Q7 The automatically designed tests can help identify potential errors or issues?
Q8 What aspects of the automatically designed tests could be improved to better meet your needs?

The first four questions assess the tool's effectiveness, while the last four questions evaluate the quality of the automatically designed tests. Two questions are open-ended (questions four and eight), and the others are multiple-choice. The multiple-choice questions were designed following the (*Likert scale*, 2006), a popular method for measuring attitudes or opinions. On this scale, respondents rate each statement on a scale from one to five, where one means they completely disagree or find it unhelpful, and five means they agree entirely or find it highly helpful. Number three means a neutral opinion.

The survey was distributed by email to a group of four test analysts: this is the total number of test analysts available to use US2Test. Represents the analysts of a particular project inside the public organization. Moreover, filling out the survey was not mandatory. The answers for the multiple-choice questions of a group of three test analysts are recorded in Table 2. The responses to the open-ended questions are exhibited in the Appendix.

Questions	Test analyst 1	Test analyst 2	Test analyst 3
Q1	4	3	5
Q2	4	3	5
Q3	5	3	5
Q5	4	4	5
Q6	4	4	5
Q7	4	4	5

Tab. 2 – Test analysts' opinion about the tool and its tests

Each column in the table represents the opinion of a different test analyst, with responses based on a Likert scale. Analyzing the responses to the first three questions, we observed that most of the feedback was positive or neutral. One test analyst was neutral and totally agreed that the tool offered significant assistance. Therefore, concerning the tool's effectiveness, we can observe that it is helpful but not a complete paradigm shift in daily routines. In the subsequent three questions, two-thirds of the respondents indicate that the tests are clear and beneficial, while one-third find them exceptionally clear.

Reading the responses to Q4 and Q8 in the Appendix, we identify different test analyst perspectives. Test analysts state the tool is useful, and at the same time, there is a consensus on the need for improvements, especially regarding fixing errors during the automatic creation of tests. For the eighth question, the feedback highlights that the effectiveness of test creation is closely tied to the quality of user stories. There is room for improvement in the tools' ability to cover all scenarios in more complex user stories.

Data in Table 2 indicates significant potential for improvement in the tool. The automatically designed tests are currently satisfactory, adhering to predefined scenarios, aiding in error identification, and being clear and comprehensible.

5.3. Feedback meeting

To complement the anonymous feedback, we conducted a meeting to gather additional feedback from the test analysts. This meeting was about one month after the responses to the survey had been collected. Thus, reflects a possible more mature opinion about the tool's impacts. During the meeting, it was clearly stated that the tool prototype had demonstrated productivity gains and is frequently used by at least two team members. After that, one analyst reported that the tool reduces up to 60% of the effort in creating tests. Although the tests designed by the tool require further adjustments to be ready for test execution, it was agreed that the tests are a quality starting point for creating tests with quality.

Addressing environmental issues that prevent some analysts from using the tool (for instance, an anti-virus that blocks the tool from working properly) and fixing defects was identified as a priority. Furthermore, during the meeting, the analysts emphasized the desire for the tool to create tests for all the sprints in a given project. Currently, the tool generates tests for all user stories in a sprint but does not generate tests for all sprints in a project.

Finally, implementing a simple graphical user interface was proposed to enhance the overall test analyst experience by reducing repetitive data entry. The meeting concluded with a consensus that the specific requirements for this interface will be discussed with the tool test analysts later.

6. Discussion

Considering the evaluation presented in Section 5, we can go back to discuss the research questions introduced in Section 1.

6.1. [R1] How to build a tool that reads user stories and automatically designs system test cases?

The response to this answer is detailed in Section 4. Thanks to the capabilities of LLMs in natural language processing, the automation of tasks that involve input and output of textual content is facilitated by the current LLMs, such as GPT-4, which has been used in this research. We made a relatively small effort to set a prompt and refine it until we got to the version presented in this study. A greater amount of time was dedicated to the automation of the approach presented in Figure 3, which requires integration with Redmine and Squash TM and the construction of a simple command-line tool. From this experience, we believe LLMs can facilitate the construction of different tools to support software testing activities.

6.2. [R2] How do the test cases designed by the tool compare to the tests designed by the test analysts?

The results exhibited in Section 5.1 bring interesting points for discussion. It could be observed that all ADT tests are related to some MDT tests and that ADT has complete coverage in the same way as MDT does. Despite that, there are differences in the number of tests and steps in both suites. The test cases automatically designed by the tool (ADT) produce a larger number of test cases and steps compared to the tests designed by the test analysts (MDT). As reported in Section 5.1, some tests in ADT, if merged, would bring similar tests in MDT. The increase in the number of steps is justified by the fact that the tests in ADT have detailed and explicit descriptions that add extra steps for the tests. While tests in MDT are more concise since they leave some points implicit. Even considering the differences, test analysts considered tests in ADT to be acceptable since they are coherent with user stories, easy to follow, and have a clear language.

A point for future investigation is to analyze the effect on the tests of ADT if UI information is provided as context information to the model. A hypothesis to be observed would be to observe whether the model would produce a smaller number of tests: possibly, individual tests would be put together because they can be executed on the same page of the SUT.

A positive aspect of the ADT tests that was not explored in the study is that the ADT tests do not contain grammatical or spelling errors. This is a positive aspect of the tests generated by the model that contributes to the quality of the tests. Moreover, due to the rules in the prompt and the format validation performed by the tool, designed tests consistently match the expected format for test cases, ensuring uniformity of tests.

6.3. [R3] What are the test analysts' perceptions of the tool and the automatically designed test cases?

Data presented in Sections 5.2 (survey answers) and 5.3 (feedback meeting) help in the discussion of the third research question. We have two dimensions to consider in this question: the perceptions about the impacts of adopting the tool and the perceptions about the tests produced by the tool.

Impacts of adopting the tool Looking at the survey answers, two-thirds of the test analysts agreed the tool has positive impacts on the efficiency of their activities, in the creation of tests, and in the process of publishing the tests into Squash TM. Considering there was a month between the initial contact with the tool and the

answers in the survey, it was a very short period for the respondents to formulate an opinion about the tool. An indication of this is the answer of Test Analyst 3 to the eighth question in the survey (refer to Appendix). This respondent explicitly states that he has just started using the tool. Conversely, by the time of the feedback meeting, the test analysts had been in contact with the tool for about two months. During the meeting, they expressed that the tool reduces up to 60% of the effort in creating tests. Also, they provide a rationale for this reduction: the tests designed by the tool are a very good starting point, but require further adjustments to be ready for test execution. This reinforces the feeling that LLMs are productivity tools rather than substitutes for human skills (Ross et al., 2023).

Perceptions about the produced tests In the last four questions on the survey, all respondents agreed that the tests designed by the tool were clear and easy to understand, they covered scenarios and acceptance criteria of the user stories, and they helped identify issues in the SUT. Regarding coverage of the tests, the respondents' perception matches with the complete coverage reached by the automatically designed test in the evaluation reported in Section 5.1. By the time test analysts answered the survey, they had the opportunity to use the tool to input user stories of different projects and reach adequate coverage for the tests. It gives a complementary indication that the tests generated by the tool have good coverage for a variety of user stories. The issue reported by test analysts when attempting to generate test cases occurred in user stories that present a specific character. Following test analyst feedback, the root cause was identified and fixed in the new version of the tool.

7. Conclusion

The paper introduces US2Test, a tool designed to automate the generation of system test cases from user stories using Large Language Models. It integrates with existing systems to suit the test process of a particular public organization. The empirical evaluation of the tool involving the organization's test analysts demonstrated that the tool effectively helps the design of test cases. A more effective test process can contribute to the quality of software produced by governmental entities and has the potential to improve government service delivery.

7.1. Related work

Previous works have considered user stories for the derivation of tests. For instance, the authors in (Pallavi Pandit, 2015) propose a systematic approach to manually design acceptance tests from the user stories. Additionally, the work (Granda et al., 2021) introduces a model-driven framework that inputs user stories, such that the acceptance criteria are described using the GWT (Given-When-That) structure, and produces automatic test scripts for desktop applications. The authors in (Mollah & van den Bos, 2023) present a step-by-step method to manually transform user stories into automatic test cases. The format for the user stories and the tests that are produced for these related works differs from ours, which accepts a less structured story and produces system tests in the format of a test management tool.

Domain-specific textual formats have also been used to produce tests. The works (Carvalho et al., 2015) and (Nogueira et al., 2019) follow a model-based testing approach (Dias Neto et al., 2007). The authors in (Carvalho et al., 2015) proposed a strategy to automatically generate test cases from Natural Language requirements (NAT2TEST - NATural language requirements to TEST cases). This approach inputs requirements in a Controlled Natural Language (CNL) that follows a well-defined grammar and vocabulary to allow the extraction of a formal model for automatic verification of requirements and the extraction of test cases. A test case is a sequence of test vectors that is the input for some external tool that formats the test for a particular context. The work (Nogueira et al., 2019) proposes a model-based approach to generate test cases for manual execution from well-structured use-case models with well-defined semantics. Use case flows are defined using a tabular format and specified as a mix of natural language and a special CNL. The produced test cases are suitable for manual execution and follow a format very similar to the format proposed by this work.

Natural language processing (NLP) Raharjana et al., 2021 has been extensively used to analyse user stories. One of the applications of NLP is to produce tests (Chinnaswamy et al., 2024; Leotta et al., 2024). More recently, large language models (LLM) have been explored to generate tests from different textual formats (Ng et al., 2004). For instance, the work (Mathur et al., 2023) proposes an approach that uses machine learning models like T5 and GPT-3 to automate the test case generation process. The input for the approach is a statement in natural language. Such a statement is not structured as a US. Moreover, the output is an unstructured test.

7.2. Threats to validity

We discuss some of the threats to the validity of this research.

Construct Validity: The proposed approach for test generation (introduced in Section 4) feeds the GPT-4 model with a fixed prompt with a fixed set of examples of user stories. The prompt structure can influence the results. Moreover, this prompt contains examples that can potentially influence test generation and limit the generalization of the results.

Internal Validity: Since analysts frequently discussed the tool before and during the evaluation, there is the possibility of an unstructured knowledge transfer between them. This informal learning process may have biased how analysts used and evaluated the tool, as their understanding was shaped by prior interactions rather than independent exploration. Consequently, this could influence perceived usability and effectiveness, potentially limiting the objectivity of the evaluation.

Conclusion Validity: The absence of statistical tests directly resulted from the small and homogeneous set of user stories. Thus, no statistical analysis could be performed in the evaluation, as the dataset lacked sufficient samples and variation to support meaningful statistical analysis. Another threat to conclusion validity is that LLM produces varying outputs for the same input, and the evaluation in this study did not control the temperature parameter, nor collected several responses.

7.3. Future work

So far, the quality of the designed test has been evaluated solely on its static properties (clarity, coverage, etc). Validating the efficacy of the designed test suites in detecting bugs is a complementary and essential aspect of the evaluation. Furthermore, recording and comparing the differences in the effort while adopting the tool needs new investigations.

We chose the GPT-4 model because it was the one made available to us by the public service. Possibly using different models such as (*Gemini*, 2025) and (*Claude*, 2025) could lead to diverse results. This is left as a future investigation.

Another future direction is to identify and control the factors that influence the quality of the tests. A complementary effort is to plan a more robust evaluation with a significant number and variety of user stories. Such a larger amount of input would facilitate the application of comprehensive statistical analysis.

The tool was designed to operate solely in the Redmine and Squash TM tools settings, so it must be updated to operate in different settings. Despite the setting's particularity, the core methodology may be applied to other settings. Adaptations to different environments and reusing the core methodology are important for future work.

Acknowledgment

We thank the test and business analysts who supported our project, as well as TCE-PE for providing space for our research team and offering financial resources that enabled the research and supported the involvement of faculty and students.

Appendix A

Answers for Q4

- **Test analyst 1:** "I liked the integration it has with Squash TM and Redmine, the formatting of the test case (this helps a lot since it creates the steps and prerequisites). I liked how it generates multiple test cases for the same story, considering both positive and negative scenarios. What I didn't like is that sometimes the tool doesn't generate test cases for all the stories."
- **Test analyst 2:** "The tool manages to create some scenarios, but it presents many errors before doing so. I believe it requires some improvement in certain areas."
- **Test analyst 3:** "Very useful."

Answers for Q8

- **Test analyst 1:** "In my opinion, the tool effectively explores test creation based on what is written in the stories. This highlights the need to continuously improve the content of the stories themselves. Just as a suggestion, it could enhance the created prerequisites, perhaps by providing more information and training to better identify these conditions."
- **Test analyst 2:** "I'm not sure if it could be improved, but in some scenarios, only the basics are created, even when the story is very detailed."
- **Test analyst 3:** "I recently started using it, and I'm still testing it in my activities."

Submitted: 31 January 2025, Revised: 26 March 2025, Accepted: 21 April 2025, Published: 19 May 2025

Abstract. This study assesses the performance of machine learning models and a rule-based expert system in classifying legal documents, specifically in distinguishing relevant from irrelevant cases. The evaluated models include Random Forest, Naive Bayes, XGBoost, SVM, and Decision Tree, alongside an expert system developed by a State Attorney from PGE-PE. The datasets, representing *Alvará*, *Arrolamento*, and *Inventário* legal processes, contain labeled instances of legal cases. The models were assessed based on accuracy, precision, recall, and F1-score. The results suggest that while machine learning models—particularly Random Forest—achieve higher accuracy and precision, the expert system outperforms in recall and F1-score, ensuring that no relevant cases are overlooked. The choice between machine learning models and expert systems depends on the legal context, requiring a balance between efficiency (reducing false positives) and reliability (capturing all relevant cases).

1. Introduction

The Office of the State Attorney General of Pernambuco (in Portuguese, *Procuradoria Geral do Estado de Pernambuco* - PGE-PE) is the government agency responsible for representing the State of Pernambuco in both judicial and extrajudicial matters. Currently, it operates with a limited staff to manage over 600,000 cases, where the efficient handling of this workload aims to protect the rights and interests of the State. This large volume of cases, combined with a workforce that partially lacks legal training, makes the proper distribution of these cases a challenge. Additionally, not all cases that go through the judiciary and involve the Attorney General's Office hold significant financial or social relevance, which affects the extent of public administration efforts. Proper classification of these cases facilitates the appropriate transfer of assets within the Attorney General's Office and ensures the protection of public funds.

This context underscores the critical need for developing an automated system capable of managing the intricate and specialized nature of legal texts, thereby enhancing operational efficiency and directing limited

resources toward high-priority cases. One solution lies in implementing a system specifically designed for the classification of legal documents. The literature identifies two primary approaches to building such systems. The first approach involves rule-based expert systems (RBS), which rely on a knowledge base consisting of a set of rules written by experts(Masri et al., 2019). The second approach utilizes machine learning (ML) models, allowing the system to identify patterns that define each document category (Magalhães et al., 2022).

RBS present both advantages and limitations when applied to the classification of legal documents. On the positive side, these systems offer simplicity and transparency, as their deterministic "if-then" rules make the decision-making process straightforward to understand and validate (Sasikumar, 2007). This level of transparency is particularly advantageous in legal contexts, where explainability is essential to fostering user trust and ensuring compliance (Zhou et al., 2023). However, this approach also comes with significant challenges. As the rule base expands, maintaining the system becomes increasingly complex, leading to difficulties in managing rule interdependencies and preserving operational efficiency. Additionally, constructing the knowledge base is a resource-intensive process, requiring extensive input from legal experts to accurately codify rules. This dependency on expert knowledge can be a significant limitation during system development(Westermann et al., 2019).

Machine learning (ML) models offer a dynamic solution to the limitations of rule-based systems in legal document classification. Unlike static rule-based approaches, ML models learn patterns directly from data, enabling adaptation to evolving legal standards and new case types without extensive manual updates. They generalize across diverse document formats, identify nuanced patterns, and efficiently handle large datasets with minimal human intervention after training. This adaptability and scalability position ML models as an alternative or complement to traditional rule-based systems(Prentzas & Hatzilygeroudis, 2007; Westermann et al., 2019).

In this context, this research was conducted with the objective of answering two key questions: (1) Are the evaluated models capable of learning the patterns embedded in legal documents and performing accurate classifications? and (2) Can machine learning models outperform rule-based expert systems developed by domain specialists when evaluated on key classification performance metrics such as accuracy, precision, recall, and F1-score? By addressing these questions, the study conducts a comparative analysis of machine learning models commonly used in document classification, such as XGBoost (Chari et al., 2021), Support Vector Machines (SVM) (Al Hasan et al., 2022), Random Forest (Bento & Teive, 2023), Naive Bayes (Dias & Cavalcante, 2023), and Decision Tree (Gêda et al., 2021), in comparison to a rule-based system built using expert-defined rules.

The comparison evaluates the performance of these approaches in classifying the relevance of document cases related to the Tax on Inheritance and Donation of Goods or Rights, which is referred to in Brazil as ICD (in Portuguese, *Imposto sobre Transmissão Causa Mortis e Doação de quaisquer Bens ou Direitos* - ICD). This domain presents unique challenges due to the legal and procedural complexity of the documents, as well as their substantial volume. These challenges include varying page layouts within the same case, processes of different lengths, and the specialized vocabulary of legal documents. The objective is to identify the approach that provides the most reliable and efficient solution for optimizing resource allocation and supporting decision-making within legal institutions. The main contributions of this study can be summarized as follows:

- This study provides a comprehensive comparative analysis of various classification models and a rule-based expert system, evaluating their performance in classifying the relevance of processes within the context of ICD documents.
- It was verified that the use of machine learning models enhances accuracy and precision but struggles with recall, highlighting a trade-off that must be considered in legal document classification.
- To the best of our knowledge, this is the first work to compare the use of machine learning models with a rule-based expert system in the context of ICD.
- This work sheds light on the challenges machine learning models face in surpassing expert systems, highlighting their limitations in recall and generalization despite achieving higher accuracy and precision.

The remainder of this article is structured as follows: Section 2 reviews related work, providing context and background for our study. Section 3 introduces the proposed methodology and details the experimental protocol applied. Section 4 presents and discusses the results, offering insights into models performances. Finally,

Section 5 concludes the paper by addressing research limitations and outlining potential directions for future work.

2. Related Works

Several studies have addressed the challenge of applying machine learning to document classification in legal contexts, highlighting its potential for improving efficiency and accuracy. The classification of legal documents has greatly advanced with the development of machine learning and natural language processing (NLP) techniques. These technologies facilitate the efficient analysis and categorization of vast amounts of legal texts, streamlining processes and significantly reducing the manual workload for law firms and judicial institutions (Noguti et al., 2020).

For instance, (Magalhães et al., 2022) conducted an experimental analysis using machine learning techniques to group and classify judicial decisions. The study examined a dataset of 430,000 decisions from the Regional Labor Court, employing text representation models based on BERT alongside clustering algorithms such as K-Means. The findings demonstrated that these methods effectively capture the semantic nuances of legal texts, offering significant support for decision-making processes within Brazil's judicial system. This research highlights the potential of advanced ML techniques to enhance the organization and analysis of complex legal data.

The work of (Polo et al., 2021) evaluated the performance of several classifiers combined with different feature extraction approaches to classify Brazilian court cases into three status categories: archived, active, and suspended The study achieved an accuracy of over 93% in the classification tasks, highlighting the effectiveness of XGBoost, MLP, and LSTM models when integrated with feature extraction methods such as BERT and TF-IDF.

Serras and Finger, (Serras & Finger, 2022) conducted a study on the use of attention-based algorithms to automate the categorization of Brazilian legal documents. The authors highlighted several challenges in the classification of legal documents, including redundancy, the use of generic terms, inconsistencies in vocabulary, and poorly defined syntactic structures within and between terms. These challenges are also present in ICD legal documents, a context in which this study aims to evaluate machine learning models.

The works found in the literature corroborate the argument that machine learning approaches can enhance the analysis and classification of legal documents. To the best of our knowledge, this is the first study to investigate the use of machine learning models for classifying the relevance of legal documents in the ICD context within a governmental organization. Furthermore, it compares these models with an expert system based on rules developed by a State Attornes.

3. Methodology and Experimental Protocol

The methodology used to build machine learning models for legal document classification consists of two main steps: preprocessing and modeling training.

3.1. Preprocessing

In the preprocessing stage, data cleaning, normalization and standardization, outlier detection and treatment, and data transformation techniques were applied. This step is crucial for improving data quality, thereby contributing to the accuracy, efficiency, and reliability of the analyzed models. The goal is to prepare raw data for analysis, ensuring it is clean, consistent, and suitable for modeling algorithms or subsequent analyses. This is essential because raw data often contains issues such as missing values, inconsistencies, noise, or inappropriate formats, which can negatively impact the results.

As previously mentioned, during the data preparation stage, a conversion function was used to transform classifications into binary values, enabling the use of vectorization with term frequency-inverse document frequency (TF-IDF). TF-IDF is a measure that combines the local importance of a word in a specific document (TF) with the global importance of that word across a collection of documents (IDF)(Cahyani & Patasik,

2021). The interpretation of TF-IDF provides insights into the relative significance of words within a specific document compared to the entire corpus. The higher the TF-IDF value, the more important the word or term.

Words with higher TF-IDF values can serve as key terms that help distinguish different documents or define the primary topics or themes of a document. These words can be used to summarize document content and construct classification models. In the TF-IDF implementation, we included only tokens that appeared in at least five documents and excluded those with a frequency greater than 90% across the corpus. Another consideration in this technique was limiting the total vocabulary size to 25,000 tokens, which corresponds to the total number present in the analyzed dataset.

3.2. Model Training

For the classification of legal texts using Machine Learning, we studied the application of five models. The first was SVM (Support Vector Machine), a supervised learning algorithm that utilizes a decision boundary, known as a hyperplane, to segregate the analyzed data and define different classes (Al Hasan et al., 2022). A notable observation about this model is that it can become inefficient when dealing with large datasets.

Another model used was Naive Bayes, a probabilistic algorithm based on Bayes' theorem that assumes feature independence. This simplification facilitates classification by analyzing only the presence or absence of specific features, which can also lead to inaccuracies in its results (Dias & Cavalcante, 2023).

Moving on to tree-based models, we also employed Decision Tree, which generates an inverted tree to make predictions. At its nodes, questions about data features are asked, branching based on the answers (Gêda et al., 2021). A critical limitation of this algorithm is its tendency toward overfitting.

The fourth model used was Random Forest. This classifier combines multiple decision trees, each trained on a random sample of the data, and considers a random subset of features to predict classifications through majority voting (Bento & Teive, 2023). However, a drawback of this algorithm is its high computational cost.

Finally, we employed XGBoost (Extreme Gradient Boosting), a tree-based algorithm where multiple weak trees are combined sequentially to create a strong model (Chari et al., 2021). This method is also prone to overfitting and requires careful tuning of its numerous hyperparameters to achieve optimal performance.

Due to the limitation of computational resources, hyperparameter optimization was not performed. For this reason, we used the values reported in the literature. The hyperparameters for these models are detailed in Table 1.

Tab. 1 – Hyperparameters used in model configurations

Model	**Hyperparameter**	**Value**
XGBoost	max_depth	2
	learning_rate	0.1
	n_estimators	600
	random_state	42
	scale_pos_weight	11.5
SVM	C	0.01
	gamma	0.001
	kernel	'linear'
Random Forest	n_estimators	980
	max_depth	48
Naive Bayes	var_smoothing	1e-9
	priors	None
Decision Tree	max_depth	10

The rule-based system developed utilizes a dictionary created by State Attorneys from the Succession and Donation Division of PGE-PE, the department responsible for overseeing the collection of taxes on inheritances

and donations from individuals and legal entities. In this dictionary, weights were assigned to words and expressions such as legal terms, assets, and values, indicating the degree of relevance of these terms, thus contributing to the final classification of the processes.

3.3. Datasets

The processes utilized in this study originate from the Succession and Donation Division (NSD) of the Pernambuco State Attorney General's Office (PGE-PE), a department responsible for monitoring the collection of taxes on successions and donations from individuals and legal entities in the state of Pernambuco.

For this study, three distinct datasets were analyzed, each containing cases labeled as RELEVANT and IRRELEVANT. Each dataset corresponds to a judicial class: *Inventário*, characterized as the formal process of asset division among heirs; *Alvará*, representing a formal authorization issued by an authority for specific activities related to the inventory; and *Arrolamento*, a streamlined inventory process for low-value cases.

In the *Inventário* dataset, which includes 11,839 records, a total of 11,566 RELEVANT cases and 273 IRRELEVANT cases were identified. In the *Arrolamento* dataset, containing 647 records, 354 RELEVANT cases and 293 IRRELEVANT cases were detected. In the *Alvará* dataset, with 392 records, 58 RELEVANT cases and 334 IRRELEVANT cases were recorded.

For the *Alvará* cases, the average word count per case was 6,849.64, with a maximum of 11,251 words and a minimum of 920 words. For the *Arrolamento* cases, the average word count per case was 7,637.70, with a maximum of 11,710 words and a minimum of 1,051 words. For the *Inventário* cases, the average word count per case was 8,341.11, with a maximum of 22,714 words and a minimum of 1 (one) word.

To conduct the experiment, the datasets were divided into training and testing sets, with **80%** allocated for training and **20%** for testing.

3.4. Performance Metrics

The system evaluation uses metrics already applied in the literature for classification tasks, which include: Accuracy – used to determine the proportion of correct predictions relative to the total predictions made; Precision – measures the proportion of true positives among all positive predictions; Recall – identifies the proportion of true positives correctly identified among all actual positive samples; F1-Score – defines the harmonic mean between Precision and Recall. However, this metric does not account for the class proportions in the dataset; and Confusion Matrix – used to graphically visualize the model's performance in classifying each class, displaying true positives, true negatives, false positives, and false negatives.

In this study, we classify processes as RELEVANT for the positive class (P) and IRRELEVANT for the negative class (N). Thus, TP (True Positive) refers to the number of samples correctly classified as positive; TN (True Negative) is the number of samples correctly classified as negative; FP (False Positive) represents the number of samples incorrectly classified as positive, and FN (False Negative) is the number of samples incorrectly classified as negative.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \tag{1}$$

$$Precision = \frac{TP}{TP + FP} \tag{2}$$

$$Recall = \frac{TP}{TP + FN} \tag{3}$$

$$F1 - Score = 2 \cdot \frac{Precision \cdot Recall}{Precision + Recall} \tag{4}$$

4. Experiments and Results

To address the question, "Are the evaluated models capable of learning the patterns embedded in legal documents and performing accurate classifications?" the performance of the classifiers was assessed using both training and test samples for each dataset. This evaluation aimed to determine their ability to generalize beyond the data on which they were trained.

Table 2 show the performance of the models on the *Alvará* dataset. Regarding accuracy, most models, including XGBoost, Random Forest, and Naive Bayes, achieve comparable results on the test set (0.88). Accuracy measures the proportion of correctly classified instances across all classes and provides a general overview of the model's performance. However, the *Alvará* dataset exhibits an imbalanced class distribution, with only 18.47% of instances belonging to the relevant class. Therefore, metrics such as Precision and Recall are more critical for evaluating the models' effectiveness in identifying relevant instances.

The precision metric evaluates the proportion of correctly identified relevant instances among all instances retrieved by the model, with higher values indicating a lower rate of false positives. In this regard, the Random Forest and Naive Bayes models achieved the best performance, each with a precision of 94% on the test sample. On the other hand, the recall metric measures the proportion of relevant instances correctly identified by the model out of all relevant instances in the dataset, with higher values reflecting a lower rate of false negatives. For this metric, the Decision Tree model demonstrated the best performance, achieving a recall of 0.72.

When comparing the training and testing results, it is evident that most models achieved a perfect performance on the training sample. However, this performance dropped drastically on the test sample, indicating that the models were significantly affected by the overfitting problem.

To address the second question, "Can machine learning models outperform rule-based expert systems developed by domain specialists when evaluated on key classification performance metrics such as accuracy, precision, recall, and F1-score?", the performance of the classifiers was evaluated using test samples from each dataset and compared against the performance of an expert system developed by a State Attorney from the PGE-PE.

Model	**Training**				**Testing**			
	Accuracy	**Precision**	**Recall**	**F1-Score**	**Accuracy**	**Precision**	**Recall**	**F1-Score**
XGBoost	1.0000	1.0000	1.0000	1.0000	**0.8861**	0.8459	0.6592	0.7034

Decision Tree	0.9793	0.9821	0.9766	0.9789	0.7077	0.7050	0.6911	0.6935

Tab. 3 – Performance metrics of models on the *Arrolamento* dataset during training and testing, with the best results for each metric highlighted in bold.

For the *Arrolamento* dataset, Table 3 presents the performance metrics of the models during training and testing. In this case, the Random Forest model achieved the best results across all evaluated metrics. However, it is evident that overfitting also affected the models in this dataset. For example, the Naive Bayes model

achieved a performance above 0.99 on the training sample but dropped to approximately 0.60 on the testing sample.

Model	Training				Testing			
	Accuracy	**Precision**	**Recall**	**F1-Score**	**Accuracy**	**Precision**	**Recall**	**F1-Score**
XGBoost	0.9958	0.9978	0.9143	0.9520	0.9764	0.6553	0.5087	0.5113
SVM	0.9754	0.4877	0.5000	0.4938	0.9768	0.4884	0.5000	0.4941
Random Forest	0.9959	0.9979	0.9171	0.9538	**0.9772**	**0.9886**	0.5091	0.5121
Naive Bayes	0.9879	0.8352	0.9938	0.8983	0.9700	0.5725	**0.5320**	**0.5430**
Decision Tree	0.9835	0.9834	0.6685	0.7469	0.9709	0.5639	0.5236	0.5326

Tab. 4 – Performance metrics of models on the *Inventário* dataset during training and testing, with the best results for each metric highlighted in bold.

Table 4 show the performance of the models on the *Inventário* dataset. The Random Forest model demonstrated a superior performance with the highest accuracy (0.9772) and precision (0.9886), highlighting its ability to correctly identify relevant cases. For the Recall and F1-Score, the best results are achieved by the Naive Bayes, demonstrating its ability to effectively balance the trade-off between precision and recall, particularly in identifying relevant instances in the dataset. When comparing the training and testing results, it is possible to observe that the accuracy metric values are relatively close in both samples. However, when analyzing the Precision and Recall results, the impact of overfitting becomes evident in most of the models. This highlights the importance of evaluating models using multiple metrics to gain a comprehensive understanding of their performance.

Addressing the first research question that guided this study, the results suggest that while the evaluated models exhibit the capacity to learn patterns in legal documents, their practical utility is constrained by certain limitations. The high accuracy achieved across models highlights their potential for the task of legal document classification; however, the reliance on this metric alone can be misleading, particularly in imbalanced datasets where metrics such as precision and recall are more indicative of real-world performance. Furthermore, the significant drop in performance from training to testing data underscores the pervasive issue of overfitting, raising concerns about the models' ability to generalize beyond the training set.

Dataset	Model	Accuracy	Precision	Recall	F1-Score
Alvará	XGBoost	**0.8861**	0.8459	0.6592	0.7034
	SVM	0.8481	0.4241	0.5000	0.4589
	Random Forest	**0.8861**	**0.9408**	0.6250	0.6885
	Naive Bayes	**0.8861**	**0.9408**	0.6250	0.6685
	Decision Tree	0.8228	0.6791	0.7245	0.6962
	Expert System	0.7595	0.8557	**0.7595**	**0.7883**
Arrolamento	XGBoost	0.7154	0.7168	0.6957	0.6982
	SVM	0.5692	0.2846	0.5000	0.3627
	Random Forest	**0.7462**	**0.7438**	**0.7314**	**0.7347**
	Naive Bayes	0.5923	0.5778	0.5702	0.5677
	Decision Tree	0.7077	0.7050	0.6911	0.6935
	Expert System	0.7000	0.6977	0.7000	0.6985
Inventário	XGBoost	0.9764	0.6553	0.5087	0.5113
	SVM	0.9768	0.4884	0.5000	0.4941
	Random Forest	**0.9772**	**0.9886**	0.5091	0.5121
	Naive Bayes	0.9700	0.5725	0.5320	0.5430
	Decision Tree	0.9709	0.5639	0.5236	0.5326
	Expert System	0.9624	0.9658	**0.9624**	**0.9658**

Tab. 5 – Comparison of model performance with the Expert System on the test set for the datasets *Alvará*, *Arrolamento* and *Inventário*, with the best results for each metric highlighted in bold.

To address the second question, "Can machine learning models outperform rule-based expert systems devel-

oped by domain specialists when evaluated on key classification performance metrics such as accuracy, precision, recall, and F1-score?", the performance of the classifiers was evaluated using test samples from each dataset and compared against the performance of an expert system developed by a State Attorney from the PGE-PE.

For the *Alvará* dataset, Random Forest, Naive Bayes, and XGBoost achieve the highest accuracy (88.61%), outperforming the Expert System (75.95%). This suggests that the ML models are generally better at correctly classifying cases across all classes. However, the Expert System achieves the highest recall (0.7595) and F1-score (0.7883), indicating that it is more effective in identifying relevant legal cases (i.e., those that should be classified as positive). This could be due to the rule-based nature of the Expert System, which is likely designed with legal expertise to minimize false negatives—ensuring that important cases are not overlooked. In contrast, while ML models have higher precision (Random Forest and Naive Bayes: 0.9408), their lower recall (0.6250) means they may fail to capture some relevant cases. This trade-off is critical, higher precision reduces false positives but may lead to missed relevant cases, whereas higher recall ensures that fewer important cases are ignored.

For the *Arrolamento* dataset, Random Forest outperforms the Expert System across all metrics, achieving the highest accuracy (0.7462), precision (0.7438), recall (0.7314), and F1-score (0.7347). This suggests that, for this dataset, the ML model is not only more consistent in correctly classifying cases overall, but it also maintains a better balance between precision and recall. The Expert System achieves slightly lower but comparable performance across all metrics (accuracy: 0.7000, precision: 0.6977, recall: 0.7000, and F1-score: 0.6985). This indicates that for *Arrolamento* cases, the ML model is more effective than the rule-based system, likely because legal patterns in this dataset are more learnable from the data than from fixed rules. The fact that ML models can optimize both precision and recall in this case suggests they may be better suited for handling the complexities of classification in this specific legal context.

For the *Inventário* dataset, Random Forest achieves the highest accuracy (0.9772) and precision (0.9886), meaning it is highly effective at reducing false positives, which is crucial when the goal is to ensure that only highly relevant cases are classified as such. However, the Expert System achieves the highest recall (0.9624) and F1-score (0.9658), meaning it is more effective at capturing all relevant cases—even at the cost of slightly lower precision. However, the Expert System achieves the highest recall (0.9624) and F1-score (0.9658), meaning it is more effective at capturing all relevant cases—even at the cost of slightly lower precision. This suggests that, for the *Inventário* dataset, the Expert System ensuring that relevant cases are not ignoreted, which is particularly important in legal contexts where missing a critical instance could have significant consequences.

Addressing the second research question, the results indicate that ML models generally achieve higher accuracy and precision, making them valuable for reducing false positives—an essential factor if the legal system aims to streamline case classification and avoid unnecessary workload on legal professionals. However, the Expert System often performs better in recall and F1-score, suggesting it is more cautious and prioritizes the inclusion of all potentially relevant cases. This is particularly important in legal contexts where missing a relevant case (false negatives) could have serious consequences, such as delays in legal proceedings or overlooked claims.

Ultimately,it can be inferred that the choice between ML models and the Expert System depends on the legal priorities for classification. If efficiency and reducing false positives are the primary goals, ML models—particularly Random Forest—are superior. However, if ensuring that no relevant case is missed is more critical, the Expert System remains highly competitive, particularly in recall-focused applications.

Furthermore, in this study, the models were evaluated using a baseline pipeline, applying TF-IDF for text embedding and implementing classical classifiers with hyperparameters derived from the literature. However, the results indicate that, despite achieving higher performance in metrics such as accuracy and precision across most datasets, the models were significantly affected by overfitting and failed to attain high performance in recall and F1-score, which are crucial for identifying relevant cases.

Thus, to enhance the performance of these models in legal document classification, future research should prioritize mitigating overfitting through advanced regularization techniques (Moradi et al., 2020), the use of contextual document embeddings (Morris & Rush, 2024), under-sampling or over-sampling strategies (Taha

et al., 2021), use of hybrid approach Villena Román et al., 2011, and hyperparameter fine-tuning (Bischl et al., 2023). Effectively addressing these challenges would improve the models' generalization to unseen data, ultimately making them more practical, reliable, and well-suited for real-world legal applications.

5. Conclusion

This study evaluated the performance of machine learning models and a rule-based expert system in classifying legal documents, specifically in categorizing relevant and irrelevant cases. The evaluated models included Random Forest, Naive Bayes, XGBoost, SVM, and Decision Tree, alongside an expert system developed by a State Attorney from PGE-PE. The datasets, representing *Alvará*, *Arrolamento* and *Inventário* legal processes, contained labeled instances of legal cases. The models were assessed based on accuracy, precision, recall, and F1-score, providing a comprehensive assessment of their effectiveness.

The findings of this study reinforced the potential of machine learning models for legal document classification, particularly in terms of precision and accuracy. The Random Forest, Naive Bayes, and XGBoost models achieved promising performance, with accuracy rates ranging from 74.62% to 97.72% across different datasets. However, as observed in previous research on machine learning in the legal domain, these models exhibited susceptibility to overfitting, particularly in recall and F1-score, emphasizing the need for techniques that could address this issue.

In contrast, the rule-based expert system demonstrated superior recall and F1-score, ensuring the identification of most relevant cases, a crucial aspect in legal contexts where false negatives could be highly problematic. However, consistent with findings in the literature, this approach had limitations regarding flexibility and precision, particularly when applied to large-scale unstructured data.

Despite the advancements presented in this study, some limitations needed to be acknowledged. First, the models were trained and tested on a specific dataset, and their generalizability to other legal domains might have required additional fine-tuning. Additionally, the absence of advanced class-balancing techniques may have influenced the recall and F1-score of the machine learning models. Future research should focus on mitigating these challenges by exploring enhanced regularization, contextual embeddings, sampling methods, hybrid approaches, and hyperparameter tuning to improve performance and robustness.

By addressing these challenges, machine learning models could become even more efficient and reliable for practical applications in the legal sector, contributing to the automation and optimization of legal document classification.

Abstract. Data analytics can support evidence-based decision-making in public policies by enabling the identification of patterns, forecasting needs, and prioritizing actions. Consequently, data-driven analysis can aid policymakers in redesigning and enhancing educational policies, such as textbook distribution for public schools. However, there is no consensus on a structured approach for descriptive analytics in this context. This study presents a descriptive approach to textual data analysis aimed at improving policy implementation and monitoring, with a focus on effort, productivity, and quality of reviews produced by textbook evaluators. Through a case study, we apply natural language processing techniques to analyze thousands of answers to rubrics during the pedagogical evaluation of a public call for literary works under the Brazilian textbook program (Programa Nacional do Livro e do Material Didático - PNLD). The PNLD is one of the most extensive textbook policies, impacting millions of students. Our findings shed light on challenges related to the effort involved and the quality of written reports in the pedagogical evaluation process. Analyzing reports, which reflect some desired and undesired behaviors of evaluators, can offer policymakers insights for making informed decisions and improving textbook programs worldwide. Our descriptive approach to textual data analysis leverages insights to enhance transparency, inform improvements, and guide policy implementation through real-time monitoring.

1. Introduction

A data science process consists of descriptive, predictive, and prescriptive steps, supporting the entire cycle of data-driven analysis and decision-making (Delen, 2019; Sharda et al., 2018). Thus, data-driven analysis has been recognized as a significant approach for supporting governments and public organizations, for instance, in developing and improving educational policies (Badrul Hisham et al., 2024; Kulal et al., 2024). Data analytics enables governments and public organizations to make evidence-based decisions by leveraging large

volumes of data to identify patterns, predict future needs, and prioritize actions (Kulal et al., 2024). Analytical techniques, such as those driven by Artificial Intelligence (AI), can impact public resource allocation and tackle modern governance challenges (Santoso et al., 2024).

In education, data analytics can inform educational policies to reduce inequalities and improve access (Pencheva et al., 2020). Data-driven analysis can also assist policymakers in redesigning and developing educational policies (Badrul Hisham et al., 2024). The Brazilian textbook program (Programa Nacional do Livro e do Material Didático - PNLD) evaluates educational materials, including literary works, to ensure high-quality tools that support learning for millions of public school students. By maintaining a structured pedagogical and technical evaluation process, the PNLD plays an important role in aligning these materials with national educational objectives (Sobrinho et al., 2023). The PNLD is an example of an educational public policy that can benefit from data-driven analysis to enhance monitoring processes and support policy reformulations.

This paper emphasizes descriptive analytics, where we analyze past events to lay the foundation for future predictive and prescriptive steps. While data-driven analysis has proven to be a relevant approach in supporting educational public policies, such as the PNLD, there is no consensus on a structured approach for conducting descriptive analytics in this context. More standardized guidelines are needed for integrating data analysis into policies, resulting in heterogeneous and context-specific approaches (Pencheva et al., 2020). We contribute to the state-of-the-art by proposing a descriptive approach to textual data analysis that supports improving policies for distributing educational materials. Our case study focuses on the PNLD 2024 public call for literary works, analyzed from three key aspects: effort, productivity, and quality. We investigate the PNLD program by analyzing the evaluation process of educational materials.

Providing well-designed educational materials to every student is a significant need that may influence learning performance (Liu, 2023; UNESCO, 2016). Public policies related to educational materials such as textbooks and literary works must include robust evaluation processes to ensure content and editorial quality. The PNLD comprises steps for enrollment/validation, pedagogical evaluation, technical qualification, choice (by public school principals and teachers), negotiation, acquisition, and distribution of educational materials (Sobrinho et al., 2023). This paper depicts the pedagogical evaluation process of PNLD, which considers the quality of contents. We expect that the data analysis from evaluation reports can support policy-makers in making informed decisions to improve this type of program.

Despite a comprehensive and centralized process, which includes steps to evaluate the educational materials rigorously, the PNLD program's pedagogical evaluation process encounters challenges that could compromise the distribution time of educational materials to students and the process quality (Silva et al., 2024).These challenges include high evaluator effort, textual inconsistencies, and report quality issues, which can compromise the program's efficiency and delay the timely distribution of materials. This issue transcends the PNLD program and potentially has implications in the countries that conduct official evaluations with similar characteristics. In the context of the Brazilian textbook policy, the pedagogical evaluation process is started when a public call for educational materials is issued, outlining the evaluation criteria to ensure quality. The call guides a rigorous blind evaluation procedure, where a series of questions and justifications are considered, leading to a partial report. A pedagogical and technical committee then thoroughly reviews this report to ensure compliance with the evaluation criteria, culminating in a final report. The evaluation process teams include five key actors: Evaluator 1, Evaluator 2, Assistant Coordinator, Pedagogical Advisor, and Pedagogical Coordinator. The involvement of multiple materials and actors adds complexity, mainly due to the hierarchical evaluation structure extending from the evaluators to the pedagogical coordinator.

We examine the relationships among the documents generated by each participant to analyze issues related to effort, productivity, and quality. As a case study, we pre-process data and analyze reports from evaluators, assistant coordinators, pedagogical advisors, and pedagogical coordinators involved in the PNLD 2024 public call for literary works. We leverage natural language processing techniques, such as text similarity analysis (Wang & Dong, 2020), to handle thousands of answers to rubrics and gain deeper insights into the challenges encountered during the evaluation process of this particular public call. Few researchers have thoroughly analyzed these complexities before textbooks and literary works receive (or fail to receive) official approval (Clark et al., 2024). Among the potential causes for the lack of data on this process may be the unavailability of comprehensive government data since this process might not be digitalized or be restricted to internal stakeholders. As partners of the Brazilian Ministry of Education, the authors have the authorization to research and innovate in the platform (PNLD-Avaliação) that supports the official approval of the textbooks.

2. Methodology

2.1. Descriptive Approach to Textual Data Analysis

We structured our descriptive approach to textual data analysis by defining our goals, Research Questions (RQs), and metrics to support the answers to the RQs. Our initial goal (Table 1) focuses on comprehending the report writing efforts of the pedagogical and technical committee. The final report serves as a written explanation of the committee's decision regarding the literary works' approval (or rejection). We identified six metrics based on text similarity (Wang & Dong, 2020) and text length, aimed at answering three RQs.

Tab. 1 – Goal 1. Understand report writing efforts from analyzing previous works of the assistant coordinator, pedagogical advisor, and pedagogical coordinator.

Question Description	Metric
(RQ1.1) What is the effort level of the assistant coordinator when reusing and editing the peer revision?	**(M1.1)** Similarity between reports from double-blind revisions and assistant coordinator.
	(M2.1) Total length of reports from double-blind revisions and assistant coordinator.
(RQ2.1) What is the effort level of the pedagogical advisor when reusing and editing the report from the assistant coordinator?	**(M3.1)** Similarity between reports from the assistant coordinator and pedagogical advisor.
	(M4.1) Total length of reports from the assistant coordinator and pedagogical advisor.
(RQ3.1) What is the effort level of the pedagogical coordinator when reusing and editing the report from the pedagogical advisor?	**(M5.1)** Similarity between reports from the pedagogical advisor and coordinator.
	(M6.1) Total length of reports from the pedagogical advisor and coordinator.

Our second goal (Table 2) centers on assessing the productivity of the pedagogical and technical committee during the report writing process. We established three metrics based on the time taken to complete tasks to achieve this goal, aiming to address three specific RQs.

Tab. 2 – Goal 2. Understand the productivity in report writing from analyzing previous works of the assistant coordinator, pedagogical advisor, and pedagogical coordinator.

Question Description	Metric
(RQ1.2) What is the productivity level of the pedagogical coordinator?	**(M1.2)** The time the pedagogical coordinator completes tasks.
(RQ2.2) What is the productivity level of the pedagogical advisor?	**(M2.2)** The time the pedagogical advisor completes tasks.
(RQ3.2) What is the productivity level of the assistant coordinator?	**(M3.2)** The time the assistant coordinator completes tasks.

Our third goal (Table 3) concentrates on evaluating the quality of partial reports provided by evaluators regarding compliance, partial compliance, and non-compliance with evaluation criteria. These partial reports serve as textual explanations of the evaluator's decisions. Quality refers to how easy the text is to understand, providing grammatically correct evaluations. To address the four RQs related to this goal, we established seven metrics based on text readability[1], complexity[2], spelling quality, length, and similarity.

Tab. 3 – Goal 3. Understand the quality of partial reports from analyzing previous works of evaluators.

Question Description	Metric
(RQ1.3) What is the writing quality of partial reports?	**(M1.3)** Readability of partial reports.
	(M2.3) The spelling quality of partial reports.
(RQ2.3) What is the level of detail in partial reports?	**(M3.3)** The total length of partial reports.
	(M4.3) The level of complexity of partial reports.
(RQ3.3) What is the level of uniqueness of partial report contents?	**(M5.3)** Similarity of reports of the same evaluator across different documents.
(RQ4.3) What is the agreement level between evaluators?	**(M7.3)** Similarity between partial reports of two evaluators of the same document.

Our fourth and fifth goals (Table 4), respectively, concentrate on the efforts and productivity of evaluators when writing partial reports regarding compliance, partial compliance, and non-compliance with evaluation criteria. We consider four levels of effort, which refer to how laborious it is to produce a text based on previous reports. No effort occurs when no changes are required from the previous reports. For instance, the assistant coordinator reused all text produced by a specific evaluator (i.e., 100% similarity, the same total length, and zero difference between the strings). Minor effort occurs when some changes are required from the previous reports. For instance, the assistant coordinator changed the writing style from the text produced by a specific evaluator. Major effort occurs when significant changes are required from the previous reports. For instance, the assistant coordinator changed the report by mentioning specific external documents, such as laws. Full

[1] Text readability refers to how easily a reader can comprehend a reporting text.
[2] The complexity of the report text is influenced by external references (e.g., laws and national curriculum).

effort occurs when changes in decisions are required from the previous reports. For instance, the assistant coordinator changed the decision from conditionally approved to reproved. Conversely, productivity measures the value generated per hour worked. To address the two RQs associated with these goals, we established three metrics based on task completion time, text length, and text complexity.

Tab. 4 – Goals 4 and 5. Understand the efforts and productivity of writing partial reports from analyzing previous works of evaluators.

Question Description	Metric
(RQ1.4) What is the effort level when writing partial reports?	**(M1.4)** Total length of partial reports.
	(M2.4) The level of complexity of partial reports.
(RQ1.5) What is the productivity level of the evaluators?	**(M1.5)** The time the evaluator completes tasks.

Our sixth goal (Table 5) centers on assessing evaluators' quality of question responses regarding compliance, partial compliance, and non-compliance with evaluation criteria. This analysis is essential because evaluators objectively state one of these three fixed possibilities for each evaluation criterion. To address the two RQs related to this goal, we defined two metrics based on the Kappa index (Cohen, 1960; McHugh, 2012).

Tab. 5 – Goal 6. Understand the quality of questions responses from analyzing previous works of evaluators.

Question Description	Metric
(RQ1.6) What is the agreement level between evaluators?	**(M1.6)** Kappa concordance between two evaluators' answers to the same literary work questions.
(RQ2.6) What is the agreement level of each evaluator with the pedagogical coordinator?	**(M2.6)** Kappa concordance between the evaluator's answer to questions and the final report.

Our seventh and eighth goals (Table 6) concentrate on evaluating the quality of justifications (associated with questions from the sixth goal) and the efforts expended by evaluators in writing them, respectively. Each evaluator produces a textual justification for the responses to the questions. To address the three RQs associated with these goals, we established six metrics based on text readability, spelling quality, length, and complexity.

Tab. 6 – Goals 7 and 8. Understand the quality of justifications and efforts in writing them from analyzing previous works of evaluators.

Question Description	Metric
(RQ1.7) What is the writing quality of justifications?	**(M1.7)** Readability of justifications.
	(M2.7) The spelling quality of justifications.
(RQ2.7) What is the level of detail in justifications?	**(M3.7)** The total length of justifications.
	(M4.7) The level of complexity of justifications.
(RQ1.8) What is the effort level when writing justifications?	**(M1.8)** Total length of justifications.
	(M2.8) The level of complexity of justifications.

2.2. Datasets

To answer our RQs, we gathered data from reports submitted during the 2024 PNLD public call for literary works (focused on the final educational years). Thus, based on the data gathered from the Brazilian Ministry of Education database, we defined four datasets to conduct our analysis: **2024_3_functions_report dataset** (1450 instances, comprising 396 reports from assistant coordinators, 491 from pedagogical advisors, and 563 from pedagogical coordinators), **2024_3_evaluators_report dataset** (927 instances, comprising reports from 181 evaluators), **2024_3_functions_question dataset** (125465 instances, comprising 42226 responses from assistant coordinators, 34821 from pedagogical advisors, and 48418 from pedagogical coordinators), and **2024_3_evaluators_question dataset** (79838 instances, comprising responses from 181 evaluators).

The original datasets contained more than 30 data fields. However, we reduced this to 15 fields to better understand the efforts and capacities of evaluators, assistant coordinators, pedagogical advisors, and pedagogical coordinators. For each dataset, we used the following data fields to conduct our analyses: **CO_call** (identification of the public call), **DS_call** (description of the public call), **CO_object** (identification of the object related to the public call), **DS_object** (description of the object related to the public call), **CO_evaluation_team** (evaluation team alphanumeric code), **DS_function** (description of function - i.e., assistant coordinators, pedagogical advisors, or pedagogical coordinators), **CO_work** (identification of the literary work), **CO_form_block** (identification of a block of an evaluation form), **CO_form_eval** (identification of an evaluation form), **CO_question** (identification of an objective question of the evaluation form), **DS_question** (description of an objective question of the evaluation form), **CO_question_response** (identification of a response to an objective question of

the evaluation form), **DS_question_response** (description of a response to an objective question of the evaluation form), **DS_question_justification** (justification for responding to an objective question of the evaluation form), and **CO_evaluator** (identification of the education professional - i.e., evaluator).

2.3. Data Pre-processing and Analysis

Our data pre-processing procedure comprises seven steps (Figure 1): data verification, data adequacy, dimensionality reduction, encoding, content verification, justification adjustment, and creation of auxiliary data fields. These steps were crucial to enable our data analysis.

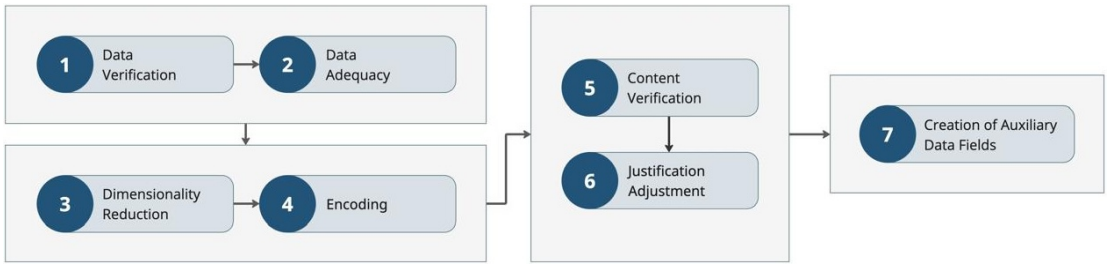

Fig. 1 – Data pre-processing steps.

We checked if the data conformed to the database structure (Step 1). A missing column label was almost always, which caused data inconsistency. We identified the issue and added two labels after the CREATED_AT and UPDATED_AT fields, ensuring the structure is correct (Step 2). Another important task was removing columns with zero or null data (Step 3). We conducted encoding tests to maintain the standard, which is almost always UTF-8. However, there were cases where the encoding only worked with Latin1, making it the extraction encoding used (Step 4). Even with the correct encoding, some columns contained terms with strange characters, which were corrected (Step 5). When a question was not justified (recorded a single space or a period), we included a default text: "Justification not recorded by evaluator" (Step 6). Additionally, when a question was unanswered, we marked it as "Not Answered". Finally, we included new columns to assist in subsequent data analyses (Step 7): **DS_JUST_CLEAN** (content without the tags in cases where the justification is in a mixed HTML + STRING format), **CHAR_COUNT** (number of characters in the justification), **WORD_COUNT** (number of words in the justification), **SENTENCE_COUNT** (number of sentences in the justification), **DS_DAYS_SPENT** (a delta between the "UPDATED_AT" and "CREATED_AT" fields, indicating the number of days worked), and **Q_EVALUATIONS_WORKED** (number of evaluations the stakeholder worked on in the public call).

Our textual transformation to numeric data relied on the Tfidfvectorizer function from the sci-kit-learn library. Additionally, we applied the Cosine, Jaccard, Spacy, and SBERT methods to analyze similarities. The Cosine similarity represents the degree of similarity between two documents (Kwangil Park & Kim, 2020). The Jaccard similarity represents the ratio of the size of the intersection over union (Verma & Aggarwal, 2020). We relied on the Cosine and Jaccard as syntactic similarity measures. Conversely, Spacy relies on word vectors to capture semantic relationships (Honnibal & Montani, 2017). Embedding is usually pre-trained on large corpora, and the Cosine calculates the similarity (Equation 2). Finally, SBERT similarity relies on sentence embeddings from a fine-tuned Bidirectional Encoder Representations from Transformers (BERT) model (Reimers & Gurevych, 2019). Similarly to Spacy, calculating similarity relies on the Cosine method. We relied on the Spacy and SBERT similarities as semantic similarity measures.

3. Results and Discussion

3.1. Effort Levels by Function

3.1.1. Assistant Coordinators

The assistant coordinators review the reports from the blind evaluations conducted by the evaluators. To understand the similarity between an assistant coordinator's report and each evaluator assigned to the same literary work, grouping by conditionally approved and reproved, we applied the Cosine, Jaccard, Spacy, and

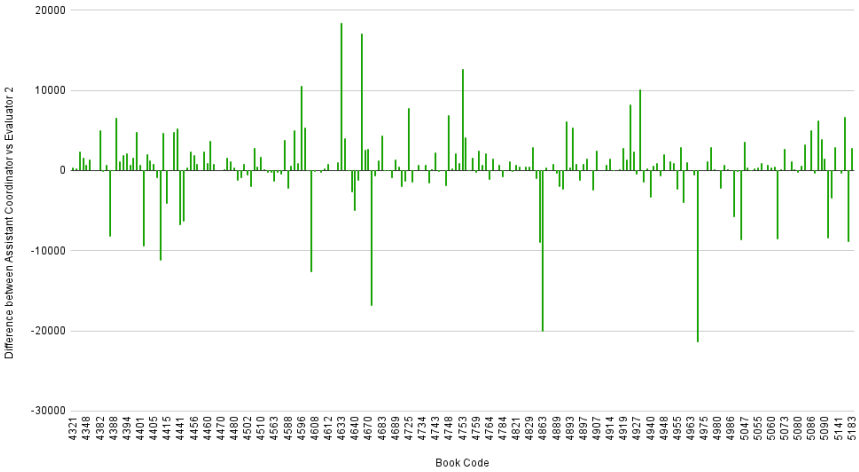
SBERT methods. We also calculated the mean, median, and Standard Deviation (SD) by grouping all assistant coordinators, considering the public call and evaluation results.

Based on Table 7, the text similarities between assistant coordinators and evaluators' reports for reproved and conditionally approved literary works were compared using four different methods. For the Cosine method, the conditionally approved literary works show a higher mean similarity (0.98) than the reproved literary works (0.66). The median is also higher for conditionally approved literary works (1.00 vs. 0.67). However, the SD is lower for the reproved literary works (0.26 compared to 0.13), indicating that, while the mean similarity is lower, there is greater variability in the conditionally approved group. For the Jaccard method, the conditionally approved literary works again show a higher mean similarity (0.99) compared to reproved literary works (0.83), and the median is significantly higher (1.00 vs. 0.86). The SD is also slightly lower for conditionally approved literary works (0.08 vs. 0.14), indicating more consistent results in the conditionally approved group. The Spacy method shows that conditionally approved literary works have higher similarity metrics, with a mean of 0.99 and a median of 1.00, compared to a mean of 0.94 and a median of 0.97 for the reproved literary works. Additionally, the SD is smaller for conditionally approved literary works (0.04 vs. 0.07), reflecting a higher consistency in the results. Finally, for the SBERT method, the conditionally approved literary works exhibit a higher mean (0.99) and median (1.00) compared to the reproved literary works (mean of 0.91 and median of 0.93). The SD is lower for the conditionally approved literary works (0.05 vs. 0.10), indicating that the similarities for conditionally approved literary works are not only higher but also more consistent. Across all methods, the conditionally approved literary works generally show higher and more consistent similarity scores compared to the reproved literary works.

Tab. 7 – Comparison of text similarities between assistant coordinators and evaluators reports for conditionally approved and rejected literary works.

	Reproved			Conditionally Approved		
Metric	**Mean**	**Median**	**SD**	**Mean**	**Median**	**SD**
Cosine	0.66	0.67	0.26	0.98	1.00	0.13
Jaccard	0.83	0.86	0.14	0.99	1.00	0.08
Spacy	0.94	0.97	0.07	0.99	1.00	0.04
SBERT	0.91	0.93	0.10	0.99	1.00	0.05

We applied the Student's t-test to determine whether there are statistically significant differences between the Cosine and Jaccard similarities of the reproved and conditionally approved literary works. For the reproved literary works, we obtained a p-value of 0 for both the Cosine vs. Jaccard and Spacy vs. BERT similarities at a significance level of 0.05. This indicates a significant difference between the means of the two samples, suggesting that the observed variations in similarity metrics are statistically significant. The difference in similarity between the Spacy and SBERT methods can be attributed to two factors. The first is the different approaches each method uses to calculate text similarity. While Spacy relies on basic syntactic and semantic features of words and sentences, SBERT uses pre-trained sentence representations in high-dimensional vector spaces, capturing more complex semantic nuances. These differences result in distinct assessments of how semantically close the texts are, with Spacy perceiving greater proximity and SBERT indicating a more considerable distance. The second factor is the writing style of the assistant coordinator and the evaluator.



For the conditionally approved literary works, we obtained a moderate p-value (0.4987) for the Cosine and Jaccard similarities based on the Student's t-test. This indicates no significant difference between the means of the two samples for these similarity metrics. Furthermore, the calculated t-statistic value of -0.0156 and the corresponding t-distribution value of 0.4938 support the conclusion that the observed differences are not statistically significant. Conversely, the Student's t-test results, when comparing the Spacy and BERT similarities, presented a high p-value (0.8031), indicating no significant difference between the means of the two samples. The calculated t-statistic value of -0.0151 and the corresponding t-distribution value of 0.4940 confirm that the observed differences are not statistically significant. In general, the high mean values of the semantic similarity metrics indicate relatively high agreement between the assistant coordinators' and evaluators' reasoning. We further explored the Cosine and Jaccard results.

We also analyzed the textual differences between the assistant coordinators' and evaluators' reports by comparing the contents of the reproved literary works. We filtered out literary works with only one evaluation and removed duplicated reports. Figure 2 illustrates the differences between the assistant coordinators' answers to rubrics (for specific literary work) and the evaluators' during the peer review process. For 65 literary

works (Figure 2a), the assistant coordinator either removed or modified some text produced by the evaluator.

(a) Assistant coordinator vs evaluator 1.

(b) Assistant coordinator vs evaluator 2.

Fig. 2 – Difference between the texts of assistant coordinators and the evaluators for reproved literary works.

The assistant coordinator added new text for 156 literary works by incorporating text from another evaluator or creating new content. There was no difference in the answers to rubrics for 12 literary works. In contrast, when considering the second evaluator (Figure 2b), the assistant coordinator removed or modified text from the evaluator for 76 literary works and added text for 147 literary works. For instance, for literary work 4415, the assistant coordinator reused part of Evaluator 1's text (resulting in a text similarity of almost 1.0 across all metrics) while removing or altering some text from Evaluator 2. The texts were also similar.

The previous discussion on text similarities and total length (word count) suggests varying levels of effort by assistant coordinators in adjusting the evaluators' answers to rubrics: no effort, minor effort, major effort, and full effort. However, to increase confidence in answering RQ1.1, it is necessary to investigate specific instances of literary works evaluations to understand better what typically leads to a major or full effort. Thus, we conducted an n-gram analysis to guide our investigation, with n up to 7.

Figure 3 combines a Kernel Density Estimate (KDE) plot (center) with a bivariate contour plot (top and side) for reproved literary works. It displays the joint distribution of two variables: n_gram (X-axis) and jaccard_sims_ngrams (Y-axis). In the central KDE plot, shades of blue indicate varying density levels, with darker areas representing higher data point density. The KDE plot reveals a higher density of points within the 0.0 to 0.2 range for Jaccard similarity, regardless of the n-gram.

This suggests a possible discrepancy in reports produced between the assistant coordinators and evaluators for disapproved works, as the Jaccard similarity is dense. Additionally, a minor density around 1.0 indicates

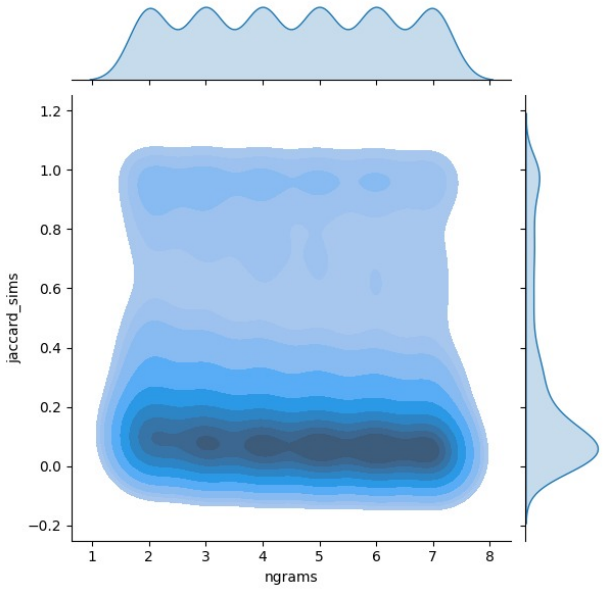


Fig. 3 – KDE plot (center) with a bivariate contour plot (top and side) for reproved literary works.

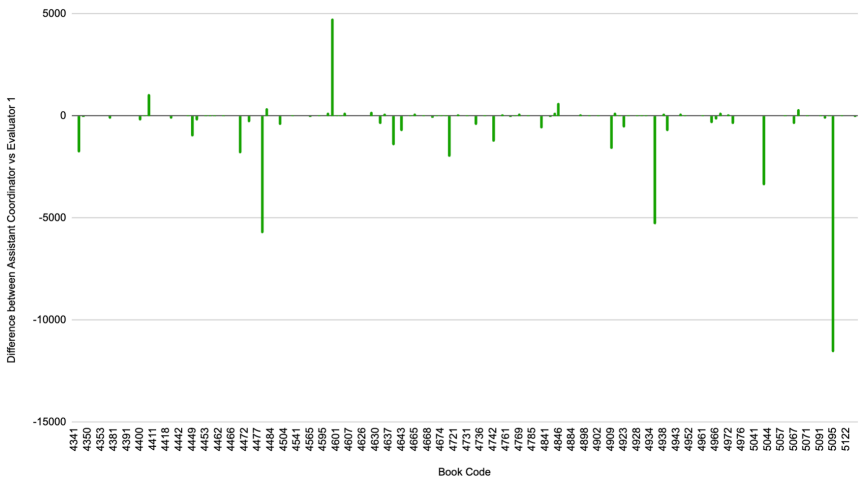
that some reports are similar, with some being literal copies. We used the visualizations presented in Figures 2 and 3 to focus our analysis on specific problematic cases, aiming to understand the evaluation issues better.

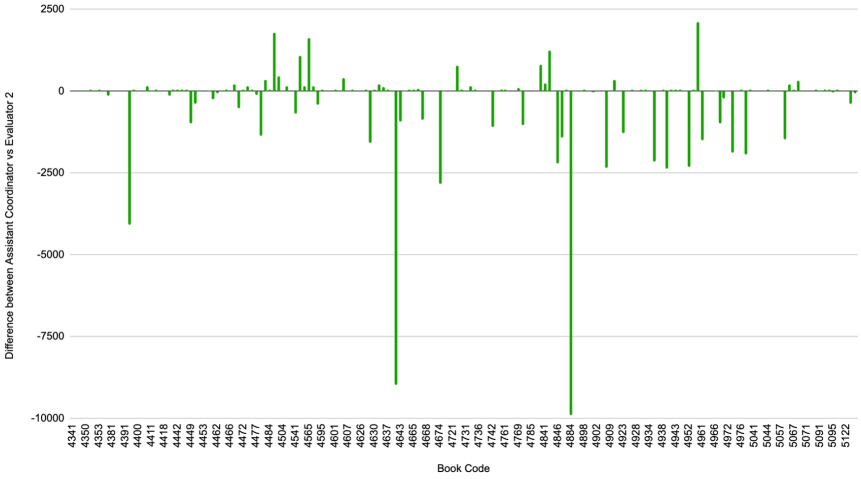
We used the same procedure to analyze the conditionally approved literary works. In the same sense as Figure 2, Figure 4 illustrates the differences between the assistant coordinators' answers to rubrics and the evaluators' during the peer review process, considering conditionally approved literary works. Some of the assistant coordinators' reports (49 in total) removed some text produced by Evaluator 1. Similarly, for Evaluator 2, 44 reports had such removals. Considering both evaluators, for 129 reports, there was no difference between the assistant coordinators' and evaluators' answers to rubrics, showing that, in many cases, assistant coordinators reuse all of the evaluators' produced text. Figure 5 also combines a KDE plot (center) with a bivariate contour plot (top and side) for conditionally approved literary works.

We used the visualizations in Figures 4 and 5 to focus our analysis on specific problematic cases from the conditionally approved. For instance, in literary works 4398 and 4449, the assistant coordinator removed the text from both evaluators and produced new text. The evaluators reproved or approved the literary work. However, the assistant coordinator reverted the decision, producing a different report (i.e., low text similarity).



Assistant coordinators' efforts tended to be significant (sometimes full effort) for the reproved literary works, involving removing or adding text from the evaluators' reports. Conversely, no effort or minor effort tends to be required when reusing at least one of the evaluators' reports for conditionally approved literary works.

3.1.2. Pedagogical Advisors and Coordinators



After the assistant coordinator finished analyzing the blind evaluations, 50 literary works were approved, 233 were reproved, and 180 were conditionally approved. Table 8 compares the similarities of the assistant coordinators' and pedagogical advisors' mean, median, and SD. Such results evidence that assistant coordinators and pedagogical advisors agree in their evaluations, with very few differences in the answers to rubrics.

Moreover, Table 9 compares the mean, median, and SD of similarities between the pedagogical advisors' and coordinators' reports. Similar to the previous case, the pedagogical coordinators usually reuse most of the text the pedagogical advisors produce, with only a few adjustments. However, the mean similarities of the reproved literary works slightly decreased for the pedagogical advisors' and coordinators' reports.

Thus, these two phases of the evaluation process typically require a minor effort to consolidate the final report

(a) Assistant coordinator vs evaluator 1.

(b) Assistant coordinator vs evaluator 2.

Fig. 4 – Difference of the answers of assistant coordinators and the evaluators for conditionally approved.

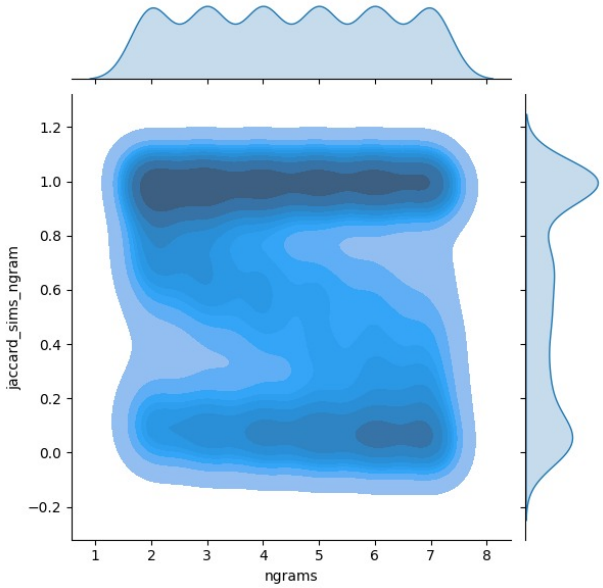


Fig. 5 – KDE plot (center) with a bivariate contour plot (top and side) for conditionally approved literary works.

Tab. 8 – Comparison of text similarities between assistant coordinators and pedagogical advisors' reports for conditionally approved and rejected literary works.

	Reproved			Conditionally Approved		
Metric	**Mean**	**Median**	**SD**	**Mean**	**Median**	**SD**
Cosine	0.90	1.00	0.18	0.93	1.00	0.20
Jaccard	0.95	1.00	0.08	0.97	1.00	0.10
Spacy	0.99	1.00	0.03	0.98	1.00	0.06
SBERT	0.97	1.00	0.05	0.98	1.00	0.06

Tab. 9 – Comparison of text similarities between pedagogical advisors and pedagogical coordinators' reports for conditionally approved and rejected literary works.

	Reproved			Conditionally Approved		
Metric	**Mean**	**Median**	**SD**	**Mean**	**Median**	**SD**
Cosine	0.83	0.90	0.18	0.93	1.00	0.18
Jaccard	0.92	0.95	0.09	0.96	1.00	0.11
Spacy	0.97	0.99	0.04	0.98	1.00	0.05
SBERT	0.95	0.98	0.07	0.98	1.00	0.07

(RQ2.1 and RQ3.1). Only a few specific cases demand a significant effort.

3.2. Productivity Levels by Function

We address RQ1.2, RQ2.2, and RQ3.2 (productivity in report writing) by analyzing the previous works of the assistant coordinator, pedagogical advisor, and pedagogical coordinators. Thus, we computed the value generated per hour worked as the ratio of the number of words of reports and the number of worked days. We analyzed the productivity of the assistant coordinators, pedagogical advisors, and pedagogical coordinators who worked in the 2024 PNLD public call for literary works. Our datasets contain software logs that record the coordinators' access from the first update to the last. The assistant coordinators' value generated per hour worked had a mean of 8.32, a median of 2.69, and an SD of 15.01. The pedagogical advisors' value generated per hour worked had a mean of 4.88, a median of 1.74, and an SD of 8.33. Finally, the pedagogical coordinators' value generated per hour worked had a mean of 3.84, a median of 1.43, and an SD of 6.11. We cannot affirm that such values evidence low productivity. This data does not accurately represent the daily work distribution. A low output value per hour worked may indicate that some evaluations are concentrated on answers to rubrics on specific days by a particular role, which is not the desired behavior (RQ1.2, RQ2.2, and RQ3.2). The Brazilian Ministry of Education staff oversees the pedagogical evaluation process team and requires frequent updates from the assistant coordinator, pedagogical advisor, and pedagogical coordinators. Higher-level functions can request the removal of lower-level functions. For instance, a pedagogical coordinator can ask for the assistant coordinator to be removed. Any function can request to be removed. During monitoring, the Ministry of Education staff or a specific function decides whether to maintain or remove personnel.

3.3. Writing Quality by Evaluators

3.3.1. Readability

We applied the Flesch and Gunning Fog indexes to understand better the readability levels of the evaluators' answers to rubrics. The Flesch index indicates reading levels as follows: 5th to 6th grade (scores 5-6), 7th to 8th grade (scores 7-8), 9th to 10th grade (scores 9-10), 11th to 12th grade (scores 11-12), college-level (scores 13-16), and graduate level (scores 17+). In contrast, the Gunning Fog index classifies texts as very easy (scores 90-100), easy (scores 80-89), fairly easy (scores 70-79), standard (scores 60-69), moderately difficult (scores 50-59), difficult (scores 30-49), and very difficult (scores 0-29).

Table 10 presents an overview of our readability analysis results using the above two measures. Values in parentheses represent the SD, and N is the number of partial reports. The readability of the partial reports varies significantly, with a difference in complexity levels. For instance, the reports for approved literary works are relatively less complex, as indicated by their lower Gunning Fog Index (mean = 19.53, SD = 3.43),

compared to the conditionally approved literary works (mean = 21.61, SD = 3.89). Reports for rejected literary works show a moderate level of complexity (mean = 16.07, SD = 5.49). This variation suggests that the less complex reports for approved and conditionally approved literary works tend to include more direct texts stating the approval, whereas the more complex ones, particularly for conditionally approved literary works, tend to be longer and include excessive detail that may not add substantial value to the decision-making process. Overall, the variation in readability indexes highlights that some texts are more challenging to read than others. This disparity arises from the inconsistent levels of detail in the reports, coupled with the evaluators' diverse writing styles. Consequently, this increases the risk of writing answers to rubrics that are less accessible and harder to interpret, which could hinder the evaluation process and decision-making.

Tab. 10 – Summary of the mean (and SD) readability measures using the Flesch and Gunning Fog indexes.

Result	N	Flesch Index	Gunning Fog Index
Rejected	66	39.6 (19.07)	16.07 (5.49)
Approved	176	34.63 (9.12)	19.53 (3.43)
Conditionally Approved	22	31.9 (19.5)	21.61 (3.89)

When analyzing spelling, the 17 answers to rubrics for approved literary works contained the fewest errors, with only three punctuation mistakes. The 115 answers to rubrics for conditionally approved literary works contained 16 errors, averaging approximately 0.14 errors per text: seven orthographic, six grammatical, and three punctuation errors. The 675 answers to rubrics for rejected literary works exhibited the highest number of errors, totaling 107 errors, averaging about 0.16 errors per text: 53 orthographic, 32 grammatical, and 22 punctuation errors. While the errors increased with the number of reports, the average errors per text remained low, indicating good writing quality in terms of orthographic, grammatical, and punctuation accuracy.

3.3.2. Level of Detail

To enhance our discussion regarding the quality, we used metrics for total length and complexity. Complexity refers to the number of citations of external documents, such as laws and the national curriculum. The total length of evaluation reports for approved literary works had a mean of 269.68, a median of 176.00, and an SD of 350.10. For conditionally approved literary works, the evaluation reports had a mean of 565.52, a median of 220.00, and an SD of 1253.28. The evaluation reports for rejected literary works had a mean of 2656.64, a median of 1219.00, and an SD of 4098.70. Thus, the evaluation reports for approved literary works are relatively short. The conditionally approved literary works show more detailed partial reports than the approved ones, while the rejected literary works partial reports are longer. This higher level of detail in rejection reports is expected, as it enhances confidence in evaluators' decisions and provides robust justification, especially considering that rejections may be subject to appeals. However, a high total length value may indicate redundant or less relevant text. We complement this analysis by using the complexity of reports, as the criteria for approvals and rejections rely on different external documents. We used regular expressions to identify mentions of external documents in the reports, relying on specific keywords (e.g., ABNT NBR) and regular expressions.

The partial reports for approving literary works had a mean of 0.42, with an SD of 0.50. Conversely, the partial reports for conditionally approving literary works had a mean of 0.50, with an SD of 0.50. The reports for rejecting works had a mean of 2.40, with an SD of 3.35. These results suggest that reports for rejecting works provide higher levels of detail due to their greater total length and number of mentions of external documents. Although the conditionally approved generally had longer partial reports than the approved literary works, they contained fewer mentions of external documents. The results suggest that evaluations could provide more details on the criteria used to approve, conditionally approve, or reject literary works (RQ2.3).

3.3.3. Level of Uniqueness

We examined the similarities in partial reports provided by the same evaluator across different literary works (RQ3.3). We organized the reports by grouping those from the same evaluator according to the classifications

of approval, conditional approval, and rejection. Grouping all reports related to approvals and the evaluators who wrote them, we observed that reports had a mean Jaccard similarity of 0.83, a median of 1, and a standard deviation (SD) of 0.29. For conditionally approved, the reports showed a mean similarity of 0.85, a median of 1, and an SD of 0.28. On the other hand, reports for rejected works presented a mean similarity of 0.48, a median of 0.45, and an SD of 0.19. Based on the results from the previous RQs, the high similarity in reports for approvals and conditional approvals was expected, as they typically consist of straightforward statements of approval or partial approval, with minimal details and nearly identical content. However, the moderate mean similarity observed in reports for rejections (approximately 50%) was unexpected, as these reports are generally the most detailed and should be unique, displaying low similarity (RQ3.3).

3.3.4. Agreement Level Between Two Evaluators

Table 11 presents the evaluators' answers to rubrics similarities for approved, conditionally approved, and reproved literary works during the peer review. The metrics indicate that the partial report texts for approved literary works have varying levels of similarity. The Cosine similarity metric shows moderate similarity, while Jaccard, Spacy, and SBERT metrics indicate higher similarities, with Spacy reaching the highest values. The SD is relatively low for the Cosine, Spacy, and SBERT metrics, suggesting a consistent pattern in the text similarities. This indicates that while the texts may differ in structure or specific terms (Cosine and Jaccard), they share semantic content (Spacy and SBERT). For conditionally approved literary works, the similarity levels are generally high, with Cosine, Jaccard, Spacy, and SBERT metrics showing comparable results. The SD values for Cosine suggest more variation in text structure and specific term usage, but the other metrics indicate consistent semantic overlap across the texts. Regarding reproved literary works, the similarity metrics also show high levels of agreement for Jaccard, Spacy, and SBERT. The SD values for the metrics suggest consistency among the reports. Overall, the level of agreement is high during the peer review process (RQ4.3).

Tab. 11 – Evaluators' answers to rubrics similarities for approved, conditionally approved, and reproved literary works during the peer review.

	Approved			Conditionally Approved			Reproved		
Metric	**Mean**	**Median**	**SD**	**Mean**	**Median**	**SD**	**Mean**	**Median**	**SD**
Cosine	0.65	0.85	0.32	0.67	0.85	0.30	0.48	0.48	0.15
Jaccard	0.82	0.95	0.21	0.82	0.95	0.20	0.75	0.77	0.13
Spacy	0.92	0.97	0.13	0.91	0.96	0.13	0.90	0.93	0.10
SBERT	0.84	0.91	0.15	0.88	0.91	0.14	0.86	0.88	0.11

3.4. Efforts and Productivity of Evaluators

By analyzing evaluators' previous works, we address RQ1.4 and RQ1.5 (efforts and productivity in writing partial reports). Thus, we reused the total length and complexity of the partial reports previously discussed to assess the effort involved in answers to rubrics. The partial reports tend to be brief and less complex for approved literary works. The partial reports for rejected literary works are generally longer. Their complexity is higher than that of approved and conditionally approved literary works. As the evaluation criteria become more stringent and the need for explanations increases, the partial reports' length and complexity rise significantly, indicating a greater effort required from the evaluators.

Moreover, we computed the value generated per hour worked as the ratio of the number of words of partial reports and the number of worked days. The evaluator 1 presented a mean of 8.30, a median of 2.55, and an SD of 19.69. The evaluator 2 presented a mean of 9.97, a median of 2.97, and an SD of 23.19. Again, this data may not accurately reflect the daily work distribution, as evaluators might concentrate tasks on specific days.

3.5. Quality of Questions Response by Evaluators

We address RQs 1.6 and 2.6 (quality in answering objective questions) by analyzing the previous work of evaluators. We calculated the Cohen's Kappa index to assess the level of agreement during the peer review

process. The average Kappa index (with SD) between the first and second evaluators was 0.61 (0.49). We also calculated the index to evaluate the agreement between the evaluators' opinions and the final decisions. The average Kappa index (with SD) between the first evaluators and the final results was 0.70 (0.46). Similarly, the average Kappa index (with SD) between the second evaluators and the final results for the same literary work was 0.68 (0.47). These results indicate a reduced level of agreement across the analyses of evaluators vs evaluators of the same literary work. There is an increase in concordance when considering the evaluators and the final decision. This finding is consistent with our earlier results, highlighting existing disagreements in evaluations, such as cases where a rejection was later changed to a conditional approval (or the contrary).

3.6. Quality of Justifications and Effort from Evaluators

We address RQ1.7, RQ2.7, and RQ1.8 by analyzing previous works of evaluators. We analyzed 79,838 questions across 467 literary works to assess the quality and effort in writing justifications. Among these, 12,363 questions lacked justifications. For approved literary works, the readability of the justifications showed a mean Flesch index of 42.48 (22.11) and a mean Gunning Fog index of 8.39 (4.59). For conditionally approved literary works, the readability scores had a mean Flesch index of 25.60 (21.18) and a mean Gunning Fog index of 9.71 (5.12). For rejected literary works, the justifications had a mean Flesch index of 33.61 (18.59) and a mean Gunning Fog index of 9.10 (5.15). The readability scores indicate that justifications for approved, conditionally approved, and rejected literary works are generally complex to read.

When analyzing spelling quality, the reproved literary works related to 2480 questions, with a mean total length of 283,28 words. The justifications presented 2165 mistakes, of which 1672 were orthographic, 411 were grammatical, and 82 were punctuation. The conditionally approved literary works were related to 307 questions (mean total length of 51,07 words), and the justifications presented 28 mistakes, of which 17 were orthographic, nine were grammatical, and two were punctuation. The approved literary works related to more than 63,845 questions, of which we analyzed 10% of them as a significant sample (mean total length of 109,6 words). The justifications presented 5712 mistakes, of which 4341 were orthographic, 1211 were grammatical, and 161 were punctuation. The number of errors increased with the number of questions. However, similar to our previous results, the number of errors was relatively low, indicating good writing quality regarding orthographic, grammatical, and punctuation accuracy.

Considering the level of detail and effort, we used total length and complexity. For approved literary works (48 and 2 outliers), the mean total length of the justifications was 152,77 words (419.02). These justifications generally exhibited low complexity, with an average of 0.40 (0.49) mentions. For conditionally approved works (181), the mean total length was 140.07 (264,81) words, and the justifications were slightly more complex than those for approved works, with an average of 0.44 (0,63) mentions. For rejected works (235), the mean total length of the justifications was 738,68 (1012,39) words. These justifications were more complex than those for approved and conditionally approved works, with an average of 1.47 (2.69) mentions. The level of detail and effort in justifications seems to increase as the decision is towards a rejection. However, the justifications present a few mentions of external documents, which may decrease clarity.

3.7. Threats to Validity

Evaluating the quality, productivity, and effort involved in writing responses to rubrics entails a degree of subjectivity. To address this problem, we provided clear definitions of these concepts. Productivity is the most challenging aspect to assess, as measuring value generated per hour—based on the number of words written—may not fully capture the complexity of evaluators' behavior. Future research may further refine these definitions to enhance objectivity. Moreover, generalizing these findings to other contexts requires a broader range of analyses, including different public calls for educational materials and textbook programs. As such, some results may not be directly applicable to educational material evaluation programs in other countries or cultural contexts without a more in-depth analysis that takes local specificities into account.

4. Conclusions

Our descriptive approach to textual data analysis enables valuable insights that can drive innovations in public policies and provide strategies to support policymakers in their decision-making processes for educational

material distribution programs. The insights fall within three key dimensions of analysis: effort, productivity, and quality of textual productions/evaluations. Answers to rubrics can reveal desirable or undesirable behaviors that directly influence the quality and efficiency of educational policies, either positively or negatively. Thus, the insights acquired from these answers to rubrics help identify critical points in evaluation processes, enhance transparency, and guide adjustments to improve policy implementation. Additionally, the approach supports monitoring, providing actionable data to inform improvements. The proposed metrics—focused on effort, productivity, and quality—support the principles of digital government by enabling real-time monitoring of the evaluation process through business intelligence tools. This contributes to increased transparency, data-driven decision-making, and greater efficiency in the management of public educational programs. When applied to actual policy implementation, our approach can help shape new processes, procedures, and rules that encourage desired behaviors while discouraging undesired ones.

The case study revealed that the peer review process for evaluating literary works during the 2024 public call was effective despite reduced agreement levels between evaluators. Assistant coordinators showed slightly higher alignment with evaluators' reasoning but played a significant role in refining reports for rejected works, often requiring substantial modifications. While productivity levels were challenging to interpret due to uneven daily work distribution, text readability emerged as a concern, particularly for rejected works, where diverse writing styles and detailed justifications increased complexity. Reports for rejections were more prolonged and more thorough, reflecting the need to enhance confidence in decisions subject to appeals. In contrast, less detailed reports for approvals and conditional approvals may risk reducing transparency, a critical aspect of public policy. Overall, collaboration between roles like assistant coordinators, pedagogical advisors, and coordinators exhibited high agreement, indicating fewer issues in this level of evaluation.

These findings present new research opportunities for process improvement, human resource training, and AI applications. For example, policymakers could leverage AI interventions to enhance the capabilities of evaluators and other roles while also reducing their workload. Generative AI-based chatbots could assist with various tasks, from fundamental analyses like spelling checks to providing text suggestions for report writing. Future research can explore the use of generative AI to improve the quality of evaluation reports.

Abstract. This study presents the development and deployment of a sentiment analysis model based on Natural Language Processing (NLP) techniques in the context of public service evaluation. The model was implemented to automate the classification of citizens' feedback on services provided by the EXPRESSO program in the State of Goiás, Brazil. Before implementation, the classification process was manual, which was time-consuming, and prone to inconsistencies. The dataset used included a wide range of citizen experiences, ensuring that the model captured a comprehensive and representative sample of comments. Preprocessing techniques such as noise removal, tokenization, stemming, and customized stopword adjustments were applied to refine the data for analysis. Among the algorithms tested, Multinomial Naïve Bayes (MNB) stood out for its slightly superior performance in identifying negative feedback — a critical class for monitoring service quality and addressing citizen concerns efficiently. The model was validated with managers to ensure its practical application and was subsequently integrated into the State's Data Warehouse (DW) to feed a real-time monitoring dashboard. Additionally, a visual interface was developed to allow managers to analyze feedback on demand. This interface includes features such as word clouds for positive and negative feedback, facilitating the quick identification of key themes, trends, and recurring issues. The integration of artificial intelligence into the EXPRESSO Program establishes a scalable and replicable framework to improve decision-making processes, enhance operational efficiency, and promote inclusivity. This methodology can be extended to other public service centers, emphasizing the vital role of AI in fostering responsive governance, improving service quality, and enhancing citizens' satisfaction.

Keywords. Sentiment analysis, Natural Language Processing, public service evaluation, machine learning, Naive Bayes.
Research paper, DOI: https://doi.org/10.59490/dgo.2025.944

1. Introduction

The use of advanced technologies has redesigned the way governments deal with challenges in the delivery of public services. In this scenario, Artificial Intelligence (AI) has proven to be fundamental for processing large volumes of data and identifying relevant patterns, becoming a strategic tool in decision-making. The application of AI in public administration has contributed to critical areas, such as health, urban mobility and with the analysis of sentiments, citizens' feedback and real demands can now be monitored, promoting greater accessibility and inclusion, as well as better services to the public.

This paper presents the development and deployment of a sentiment analysis model based on Natural Language Processing (NLP) in the EXPRESSO Program, of the Government of the State of Goiás. The initiative used a representative sample of feedback from service channels spread throughout the State, reflecting the diversity of citizens' demands. The implemented solution automates the classification of comments into three categories — positive, neutral, and negative — allowing managers to quickly identify critical points in the services offered and proactively meet the main demands.

The approach adopted sought to optimize processes and also promote more inclusive public management, by giving voice to citizens and ensuring that their experiences and opinions are taken into account in the improvement of services. Before the implementation of the model, the classification of these comments was carried out manually, being time-consuming and being subject to inconsistencies. Now, with AI, it is possible to process large volumes of data in seconds, increasing the accuracy and efficiency of the analysis. The methodology developed proved to be scalable and replicable, with the potential of expansion to other call centers, which is the most widely adopted public service model throughout Brazil.

This work reinforces the role of AI in promoting a more efficient public administration that is guided by the real demands of the population. It also evidences how technology can be a powerful tool to give visibility to citizens' voices, making public services more transparent, accessible, and inclusive.

2. Related Work

2.1 Artificial Intelligence

Artificial Intelligence (AI) is a field of computer science focused on developing systems capable of performing tasks that typically require human intelligence. These tasks include learning, pattern recognition, decision-making, and problem-solving. AI leverages advanced algorithms and large volumes of data to train models that simulate aspects of human reasoning (Russell & Norvig, 2021).

The integration of artificial intelligence (AI) into public services is increasingly recognized as a solution to enhance interactions between citizens and the government. O'Neill (2021) highlights that AI adoption in public administrations can optimize processes while improving the government's ability to meet the population's needs more effectively. AI-driven systems, such as chatbots and predictive data analysis, can streamline public service operations, enhancing the quality of services provided.

Chien and Chen (2020) demonstrate that digital transformation in the public sector, driven by AI, is not limited just to task automation, but it involves the creation of new governance models. AI-based approaches have emerged as crucial monitoring tools, enabling public managers to identify patterns and societal needs with greater precision. This transformation fosters greater transparency in public administration and enhances communication efficiency alongside the society.

These innovative approaches allow public managers to better understand societal perception, identify priority areas for improvement, and develop targeted strategies to enhance public service delivery. Such initiatives reinforce the importance of leveraging technological tools to create a public administration that is more responsive to citizens' needs and fosters a better government-society engagement.

Models that Inspired the Use of AI in Public Services:

- **United Kingdom – National Health Service (NHS):** The UK's National Health Service employs AI to improve medical diagnosis accuracy and forecast future hospital demands. The "Streams" system, developed in collaboration with DeepMind, analyzes patient data in real-time to identify signs of acute kidney failure, enabling quicker interventions. (Royal Free London NHS Foundation Trust & DeepMind. "Our work on Streams." 2021. Available at: https://www.nhs.uk)
- **United States – Internal Revenue Service (IRS):** In the United States, the IRS has adopted AI systems to detect tax fraud and enhance customer service. By employing advanced algorithms, the IRS identifies irregularities in tax returns more efficiently, saving millions of dollars in manual audits. (Internal Revenue Service. "IRS Artificial Intelligence in Tax Compliance." 2022. Available at: https://www.irs.gov)
- **Estonia – X-Road System:** Estonia, a leader in digital transformation, utilizes AI in its X-Road system to integrate public services. Through this platform, citizens can access a wide range of government services online, from business registration to medical consultations. AI analyses service usage to optimize access and identify areas for expansion. (E-Estonia. "X-Road: The Backbone of Digital Estonia." 2022. Available at: https://e-estonia.com)

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

- **India – Ayushman Bharat Health System:** In India, the Ayushman Bharat program, focused on healthcare, uses AI to monitor and predict disease outbreaks and optimize medical resource planning in underserved regions. This initiative has saved lives by anticipating public health crises. (National Health Authority of India. "Leveraging AI in Ayushman Bharat." 2022. Available at: https://www.pmjay.gov.in)
- **China – Urban Monitoring and Intelligent Mobility:** Several cities in China, such as Hangzhou, employ AI systems for intelligent mobility, including Alibaba's "City Brain" platform. This system analyses real-time traffic data to reduce congestion and improve emergency response. As a result, travel times in urban areas have significantly decreased. (Alibaba Cloud. "City Brain: Smart Cities Powered by AI." 2021. Available at: https://www.alibabacloud.com)

2.2 Machine Learning

Machine Learning is a subfield of artificial intelligence that enables computational systems to learn and improve their performance when exposed to data and past experiences (Alpaydin, E. (2020). Introduction to Machine Learning. MIT Press). This technology is widely used to solve complex problems, automate processes, and perform tasks involving the transformation or classification of large volumes of data.

Machine learning provides the foundation for systems to learn from data and enhance their performance as they process new information. When applied to the field of **Natural Language Processing (NLP)**, this capability is expanded, allowing computers to understand and analyze human text automatically. One of the possible applications of NLP in public administration is **Sentiment Analysis**, which can interpret emotions and sentiments expressed in the citizens' comments. This becomes a valuable tool for assisting public managers in understanding citizens' demands for improved public services.

2.3 Sentiment Analysis

Sentiment Analysis, according to Verma (2022), plays an important role in promoting innovation, transparency, greater citizen participation, and efficiency in public administration. This technology not only enhances communication between the government and society but also provides practical solutions to complex problems, such as traffic congestion, crime prediction, and disaster management. Applications in areas such as **smart governance, smart mobility, smart infrastructure, and smart living** serve as the foundation for the development of more connected cities.

Verma (2022) also highlights that by combining **supervised learning** techniques, sentiment analysis enables the transformation of large volumes of data into actionable insights. Additionally, it can assist in developing strategies to create smarter and more inclusive environments and services.

2.4 Multinomial Naïve Bayes Classifier

The Multinomial Naïve Bayes (MNB) model is based on Bayes' Theorem for classification tasks. Known for its simplicity and efficiency, it is referred to as "Naïve" due to its assumption of independence between features. The algorithm estimates the probability of assigning a given item to a specific class, particularly excelling in text classification based on the words contained in documents.

The multinomial approach stands out by considering the frequency of word occurrences in a document rather than treating words merely as present or absent. This characteristic makes it particularly effective in contexts where term repetition conveys meaningful information for categorization (ABBAS et al., 2019). In addition to this feature, MNB is easy to interpret and demonstrates good processing performance, making it a widely used tool in text classification applications (ARAR & AYAN, 2017). Notably, MNB achieved the highest accuracy in categorizing "negative" feedback, which was the target class for monitoring public services provided by the government of Goiás.

Tab. 1 - Comments and Occurrences by Polarity.

Polarity	Comments	Total Occurrences
Positive	"O atendente foi muito educado." (Attendant was very polite) / "O serviço foi rapido." (The service was fast)	2
Negative	"O sistema é lento e continua travando." (System is slow and keeps getting stuck) / "Terrível." (Terrible)	3
Neutral	"Queda de energia afetou computadores." (Power outage affected computers)	1

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Probabilities:

- Positive: P (pos) = 2/6 = 0,33P
- Negative: P(neg) = 3/6 = 0,50
- Neutral: P(neu) = 1/6 ≈0,17

MNB utilizes message frequencies to calculate the probabilities of each polarity. This method serves as the foundation for estimating conditional probabilities in text classification.

3. EXPRESSO: Citizen Service Program and Its Evaluation Methodology

In October 1999, the first **Vapt Vupt** unit was inaugurated at Buriti Shopping, located in Aparecida de Goiânia, Goiás, with the primary objective of consolidating and simplifying access to public services at different levels—federal, state, and municipal—while also including private companies that serve public interests. Since then, the integrated citizen service model developed in the State of Goiás has become a benchmark in the public services delivery. (https://vaptvupt.go.gov.br/sobre-vaptvupt)

In Brazil, integrated service center models have become a reference in public service delivery, with the State of Goiás being one of the pioneers in adopting this approach through **Vapt Vupt**. According to Lara and Gosling (2016), the management of the relationship between citizens and public administration should be structured based on strategies that promote greater citizen participation and satisfaction, aligning services with their expectations. The integrated service system created in Goiás has counterparts in other brazilian states, such as **Poupatempo** in São Paulo, the **Serviço de Atendimento ao Cidadão** (SAC) in Bahia, the **Organização de Centrais de Atendimento** (OCA) in Acre, the **Unidades de Atendimento Integrado** (UAI) in Minas Gerais, **Ganha Tempo** in Mato Grosso, **Ceará Cidadão** in Ceará, and **Na Hora** in the Federal District.

Goiás State Law No. 20.846, enacted on September 2, 2020 (Goiás, 2020), established the citizen service policy in the State of Goiás and created the **EXPRESSO Program**. This program introduced a new model of service delivery to citizens, integrating civil servants, services, and users in a fast, practical, and decentralized manner. Currently, six service channels are available: **Vapt Vupt, Balcão (Service Desks), Correios (Post Office), Web, APP**, and **Self-Service Totens**.

Each of these channels offers a different service approach, with some being in-person (**Vapt Vupt, Balcão, and Correios**) while others provide digital services (**Web, App, and Self-Service Totens**). Each channel serves a specific audience: in-person channels cater to citizens in the cities where they are located as well as in nearby regions, whereas digital channels are accessible to all residents of the State of Goiás.

At the end of the service, citizens are given the option to evaluate their experience and provide feedback. The requirements and evaluation criteria for EXPRESSO services were established by the **Secretariat of Administration (SEAD)**, in compliance with State Law's Article 59, which considers the following aspects:

- **User satisfaction**
- **Service quality**
- **Compliance with commitments and deadlines established for execution**
- **Number of user interactions**
- **Measures adopted by the public administration for service improvement and enhancement**

The evaluation methodology employs the **NPS (Net Promoter Score) scale**, developed by Reichheld (2003), a well-established tool for measuring user satisfaction. First, the user assigns a rating, followed by additional questions to understand the reasons behind the given score. The results classify users into three distinct groups:

- **Promoters (score of 9 or 10):** Users who positively evaluate the service and often provide constructive suggestions.
- **Neutrals (score of 7 or 8):** Users who evaluate the service but typically do not make recommendations or do so with reservations.
- **Detractors (score of 0 to 6):** Users who are dissatisfied with the service

According to **SEAD – State Secretariat of Administration (2024),** the evaluation form presented to citizens is structured as follows:

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

- **NPS question (0 to 10) to assess the premises physical infrastructure.** After selecting a score, follow-up questions are provided to justify the rating.
- **NPS question (0 to 10) to assess service delivery.** Additional questions follow to justify the given score.
- At this point, the citizen is invited to evaluate the service and/or leave a comment, both optional.
- If the citizen chooses to evaluate the service, an **NPS question (0 to 10)** is presented, followed by justification questions.
- At the end of the form, the citizen is once again invited to leave a comment, which is optional

Since most of the questions are quantitative, they are analyzed using statistical methods. Comments were manually reviewed by the technical team, which applied manual filters to remove noise, blank comments, or those containing irrelevant words. After filtering, the team individually analyzed each comment, classifying them into the following categories: **Praise, Inquiry, Complaint, Suggestion**, or a combination such as **Praise/Complaint** and **Suggestion/Complaint**. These last two classifications were used when a citizen addressed two issues simultaneously within the same comment.

From May 2022 to December 2023, a total of **71,785,073 services** were provided through the EXPRESSO channels. Since feedback is optional, **437,627 feedback responses** were received during this period, representing **0.61% of the total services provided**. Within this timeframe, **95,000 comments** were submitted, accounting for **0.13% of services and 21.70% of the total feedback responses**.

Although proportionally small, the sample is statistically significant. When considering only the feedback data **(437,627 out of 71,785,073 services)**, this citizen survey demonstrates a **95% confidence level** with a **margin of error of just 0.15%**. When analyzing only the data collected through comments, the margin of error increases to **0.32 percentage points**, but the confidence level remains at **95%**. Given that the feedback originates from both digital and in-person service channels across multiple locations in the State, it is reasonable to assert that the collected feedback is representative.

Monthly reports on user feedback regarding EXPRESSO services are published via https://www.go.gov.br/ and https://goias.gov.br/administracao/transformacao-da-gestao-publicos, from which the numbers used in this research were obtained.

Based on these findings, the **Subsecretariat for Innovation in Management and Public Services** (In portuguese Subsecretaria de Inovação da Gestão e dos Serviço Público) of SEAD identified an opportunity to automate the classification of citizen comments on EXPRESSO services, optimizing the manual process. Before implementing the new methodology, this process took an average of **two working days per week for each monthly batch of comments**. The manual approach was time-consuming and prone to inconsistencies due to human subjectivity, especially in ambiguous classifications such as sentiment combinations.

Given this scenario, the primary objective was to **apply AI techniques to automate comment classification**, reducing processing time and increasing result consistency. A project was then proposed to develop a sentiment **analysis model**, named **ANE – Análise Expresso** (EXPRESSO Analysis), leveraging **NLP** concepts. This approach enabled the reclassification of comments into three **more objective** categories: **Positive, Neutral, and Negative**.

4. Research Methodology

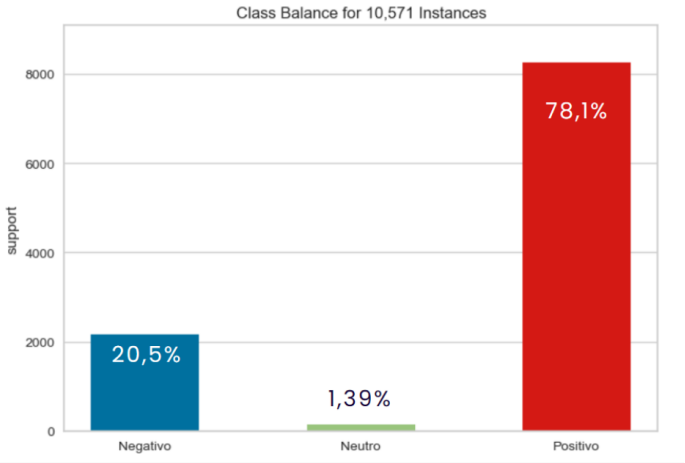
The actions carried out in this research can be summarized in the following processes: data selection, data preprocessing and cleaning, data transformation, training and evaluation of classification algorithms, classification validation with managers, and finally, script adaptation for production.

Understanding the problem and the dataset is essential for applying NLP techniques. An initial exploratory analysis was conducted to identify and address data inconsistencies, textual noise, and critical issues such as class imbalance.

The development of the sentiment analysis model was completed in approximately eight months and employed supervised learning, as it is widely used in sentiment classification problems and is highly efficient when working with labeled data (LIU, 2012). With supervised learning, manually classified examples are provided during training, allowing parameter adjustments to refine the mapping of textual features to the target classes. This approach also ensures scalability, enabling the application of the model to large volumes of future data.

4.1 Data selection

The analyzed comments were collected directly from the EXPRESSO feedback systems in .csv format, with our main



Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

focus on two columns: "Service Channel" and "Leave your comment here", the latter being our primary column containing citizen's feedback. For the initial study, a two-month sample of comments—June and July 2023—was used, totaling 10,571 comments.

Initially, a task force was organized to adjust the targets of the previous manual classification, which included six initial categories (PRAISE, QUESTION, COMPLAINT, SUGGESTION, or combinations such as PRAISE/COMPLAINT and SUGGESTION/COMPLAINT). This step was crucial for methodological approaches in Supervised Learning, allowing the model to be trained with greater accuracy. The comments were then reviewed and reclassified into three categories: POSITIVE, NEUTRAL, and NEGATIVE. This new classification became the updated target, defined as **Previsão_de_Sentimentos**, now containing only three classes.

During the initial analysis, we identified a significant imbalance in the dataset, as shown in Fig. 1. Most of the received comments had a positive tone, while the examples classified as negative—our primary focus for identifying opportunities to improve public services—were underrepresented.

Fig. 1 - Distribution of comments (June/July 2023).

This imbalance interfered with the model's training, leading to overfitting issues. In other words, the model performed well on training data but showed lower performance on new data, indicating poor generalization. This behavior often occurs in imbalanced or insufficiently representative datasets (GOODFELLOW et al., 2016).

To address this issue, we opted to strategically expand and refine the dataset. We requested additional feedback from the EXPRESSO system, incorporating comments from 03/2022 to 12/2023—totaling approximately 95,000 comments—with the goal of obtaining a higher number of negative examples. This strategy resulted in a more representative and balanced dataset.

4.2 Preprocessing

Textual databases often present challenges related to the quality and structure of texts. Issues such as grammatical errors, duplications, and the presence of irrelevant terms are common, especially in citizen comments that use informal language.

To address these issues, we applied a sequence of specific treatments in the preprocessing phase, which involved the following activities:

a) **Noise removal:** Irrelevant elements for analysis were removed, such as special characters, isolated numbers, excessive repetitions of letters or words (e.g. "sooo good!"), URLs, and other symbols that could introduce noise into the data. This step was essential to clean up the text and ensure greater consistency in the data (AGGARWAL & ZHAI, 2012).

b) **Text normalization:** The texts were converted to lowercase, unnecessary punctuation was removed, and linguistic standardizations were applied. This step helped to standardize the data format, reducing variability generated by different writing styles and typographical errors.

c) **Tokenization:** The texts were then divided into smaller units, called "tokens," which can represent words, phrases, or even characters, depending on the level of detail required. For this process, we used the Natural Language Toolkit library (NLTK), a specific module for tokenization, called tokenize. The NLTK library is widely used due to its broad application in NLP. Below is a demonstration of the tokenization process:

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Original text: Ótimo atendimento, foi tudo rápido e prático! (Great service, everything was fast and practical!)
Punctuation removal: Ótimo atendimento foi tudo rápido e prático
Tokenization into individual words: [Ótimo, atendimento, foi, tudo, rápido, e, prático]
Resulting tokens: ["Ótimo", "atendimento", "foi", "tudo", "rápido", "e", "prático"]

d) **Stopwords:** Stopwords are common words, such as articles, prepositions, and conjunctions, that generally have little informational value (Pang & Lee, 2008). When processing large volumes of text, removing stopwords helps with the analysis and also saves computational resources. However, this step needs to be carefully considered based on the objective, as some words, like "não" (not), can completely alter the meaning of a sentence in sentiment analysis. By removing the word 'não', phrases like 'não é bom' (it's not good) or 'não gostei do atendimento' (I did not like the service) would lose their negative context, hindering the model's ability to correctly identify the sentiment polarity. To solve this problem, we adjusted the default stopwords list. This approach improves the effectiveness of sentiment analysis, particularly in scenarios where nuances, such as negative statements, are relatively important for understanding the text (Aggarwal & Zhai, 2012).

e) **Stemming:** Stemming is an essential technique for NLP that reduces words to their roots or stems by removing suffixes and other endings. The goal is to standardize words that share the same semantic core, such as:

Original words: "atendido" (served), "atendimento" (service), "atender" (to serve)
Stemming to root form: "atend" (serve)
This standardization simplifies text analysis by reducing the dimensionality of the data and grouping similar terms together to improve the efficiency of analytical models (Manning, Raghavan & Schütze, 2008).

4.3 Data transformation

After preprocessing the data, we began the data transformation phase, which aims to adapt textual data into a more structured and suitable format for analysis. According to Manning, Raghavan, and Schütze (2008), machine learning and artificial intelligence models cannot directly process text in its original format, as they operate primarily with numbers and mathematical matrices. Therefore, it is necessary to transform texts into numerical representations so they can be used as input for classification and analysis algorithms. This process is known as vectorization.

Vectorization converts words, phrases, or documents into numerical formats that represent their features. Text-based machine learning models, such as sentiment classifiers, are better able to recognize mathematical patterns within vectors. As such, transforming textual data into vectors is essential to enable models to identify relationships, similarities, and semantic differences between words.

For the **ANE project**, we used the following approaches:

a) **Bag of Words (BoW):** Implemented using the CountVectorizer function from the scikit-learn library. This technique transforms texts into a word frequency matrix, where each row represents a sentence or document, and each column represents a unique word in the vocabulary. BoW is effective in identifying the presence or absence of specific words and works well in tasks that do not require complex semantic interpretation.

b) **Custom Tokenization:** This was performed using the TweetTokenizer from the nltk library, which was configured as a custom tokenizer in the CountVectorizer. This technique is especially useful for handling informal language found in comments or tweet-like texts, correctly processing hashtags, emojis, and abbreviations.

Simplified Example of Vectorization Used:

Corpus = ["Atendimento muito ruim" (Very bad service), "Atendimento excelente e rápido" (Excellent and fast service), "Péssimo atendimento" (Terrible service), "Atendimento muito bom" (Very good service)]

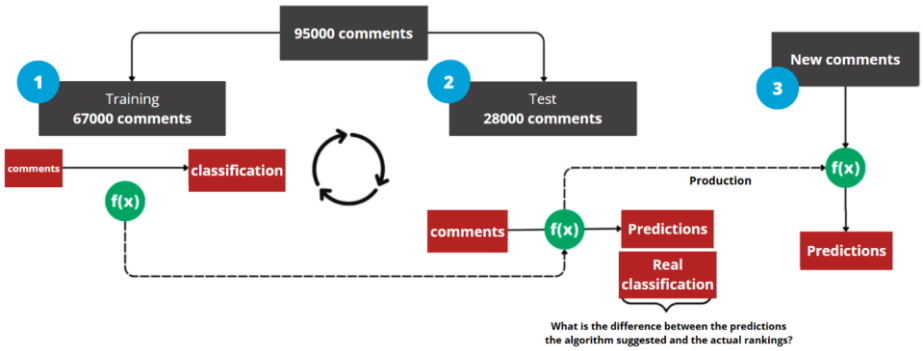
Expected Output – Generated Vocabulary:
{ 'atendimento': 0, 'muito': 4, 'ruim': 6, 'excelente': 2, 'rápido': 7, 'péssimo': 5, 'bom': 1}}

Each unique word in the corpus is assigned an index (its position in the vectorized form).

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

For example:

atendimento → 0
muito → 4
ruim → 6



Vectorization of the sentence: "Atendimento muito ruim" (Service very bad)
[1, 0, 0, 0, 1, 0, 1, 0] #Atendimento muito ruim
The word atendimento (index 0) appears once.
The word muito (index 4) appears once.
The word ruim (index 6) appears once.
All other words have a frequency of 0 in this sentence.

The chosen approaches aim to address the characteristics of the analyzed comments, seeking to balance simplicity and effectiveness in pattern extraction. The combination of Bag of Words with custom tokenization proved to be efficient in handling the informal and unstructured nature of the texts.

4.4 Training and evaluation of classification algorithms

We used the traditional split to train and test the model, dividing the data into two subsets as shown in Fig. 2: training set (70%) – used to adjust the model parameters, and test set (30%) – reserved for evaluating the model's performance on unseen data.

Fig. 2 - Training and Test Split.

For the ANE project, we tested four algorithms to select the one with the best performance in the negative class. The tested algorithms were Logistic Regression, Support Vector Machines, Multinomial Naïve Bayes, and Random Forest. These algorithms are traditionally recognized for their efficiency in classification tasks, especially in multi-class categorization problems (McCallum & Nigam, 1998).

The models were evaluated using widely recognized classification metrics, such as precision, recall, F1-score, and accuracy. These metrics were applied to analyze the performance of the different algorithms in identifying patterns and correctly classifying comments within the dataset.

Table 2 presents the accuracy of the models tested for the comment classification task.

Tab. 2 - Overall accuracy of tested algorithms.

Algorithms	Accuracy
Logistic Regression	0.955577
Support Vector Machines	0.951323
MNB	0.950378
Random Forest	0.858223

Although the Multinomial Naïve Bayes (MNB) model did not achieve the highest overall accuracy, it stood out in a crucial aspect of our problem. The MNB model exhibited the highest precision and recall for the negative class, whereas the other models achieved approximately 90% accuracy in this class, which is the primary focus of this project. Accurately classifying negative comments—often characterized by informal language, abbreviations, or more subtle sentiments—was essential for choosing MNB.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

We initially experimented with the Gaussian Naïve Bayes (GaussianNB) variant, which assumes continuous feature distributions. However, since our input features were derived from vectorized textual data using TF-IDF (Term Frequency-Inverse Document Frequency)—a more suitable representation for discrete data—we also evaluated the Multinomial Naïve Bayes (MultinomialNB) algorithm. The MultinomialNB model performed better, particularly in handling the frequency distribution of words commonly found in natural language data. Consequently, we selected MultinomialNB as the Naïve Bayes proxy in the final comparison. The model was trained using its default hyperparameters: alpha = 1.0 for Laplace smoothing, fit_prior = True, and class_prior = None.

As observed in Fig. 3, the recall evaluation shows that the performance of the Multinomial Naïve Bayes model is slightly superior to the other tested algorithms.

Fig. 3 - General evaluation of the Multinomial Naïve Bayes model.

	What proportion of identifications were actually correct? PRECISÃO	How good is the model at predicting the class? RECALL	Balance between precision and recall F1-SCORE	Sample quantity SUPPORT
NEGATIVE	0.91	0.92	0.91	4385
NEUTRAL	0.84	0.12	0.20	643
POSITIVE	0.96	0.99	0.97	23937
accuracy			0.96	28965
macro avg	0.91	0.67	0.70	28965
weighted avg	0.95	0.96	0.95	28965

This result highlights the strength of MNB in handling text data with class imbalances or sparse distributions. Its probabilistic approach and sensitivity to word frequencies made it slightly more effective in identifying and recognizing patterns associated with negative sentiment. On the other hand, models like Logistic Regression and Support Vector Machines, despite achieving higher overall accuracy, were not as efficient in classifying this target class.

These findings reinforce the importance of aligning the model selection with the specific objectives of the analysis. For the ANE project, prioritizing the classification of negative feedback was essential, justifying the choice of Multinomial Naïve Bayes.

4.5 Algorithm Validation

The algorithm validation phase aimed to ensure that the developed model met the project objectives and the practical needs of monitoring Expresso services. This process was carried out in collaboration with the managers responsible for these operations to ensure that the chosen model provided acceptable metrics and produced coherent and useful classifications for decision-making.

For the managers' validation, an executable visual interface was developed that allowed analysis from the .csv file. The application enabled data to be locally loaded for classification and validation by the managers, based on the extracted file with evaluations from any unit and period. The local ANE - Análise EXPRESSO model allowed the comment classification in just a few seconds, highlighting those ones that required immediate attention.

The interface also included a feature for visualizing word clouds separated by class ('positive' and 'negative'), providing an overview of the most frequent terms and helping managers identifying patterns in the comments. In the negative comments (Fig. 4), the word cloud highlights recurring issues such as 'delay' or 'line', which may indicate critical areas that need to be prioritized. In the positive comments (Fig. 5), signs of efficiency or good service are quickly identified. This macro-level visualization of comments facilitates the identification of critical points to be analyzed.

Fig. 4 - Word Cloud with the Negative Class.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Fig. 5 - Word Cloud with the Positive Class.

After the validation by managers and the approval of the model's efficiency in categorizing feedback, especially negative comments, fine-tuning adjustments were made to enhance alignment with the operational context. This included incorporating words and expressions commonly used by the team for service testing.

From that point, the script was adapted for integration with the Data Warehouse (DW) of the State of Goiás, enabling the classification of stored comments. To save and load the model, Python's **Pickle** module was used. However, since the model includes lambda functions, the additional **Dill** package was required (Izadi, 2019). Following these adaptations, the Pickle file was incorporated into a data processing routine, which now feeds a service monitoring dashboard. This dashboard, available exclusively to managers, utilizes the AI model developed to analyze citizen feedback, classifying their experiences with public services into predefined categories: positive, neutral, and negative. On average, 120 to 200 comments are processed and analyzed daily.

5. Discussion

This study highlighted the significance of applying NLP techniques to analyze comments related to the EXPRESSO services in the State of Goiás. The automated classification facilitated a deeper understanding of citizen feedback and enabled more efficient real-time monitoring, becoming an essential tool in overseeing the quality of public services.

A key point was the analysis of the neutral class. Although this class showed low accuracy due to the limited number of examples available in the training dataset, the model proved promising by effectively capturing neutral comments in new samples. This shows that, despite initial limitations, the model can recognize nuances in texts, indicating that the adopted approach is robust and has potential for refinement. A future improvement would involve expanding the dataset, especially by adding more examples of neutral comments, to reduce bias and improve performance in this class.

Another relevant aspect of the study was the geographical coverage of the database. The used data sample significantly represented the different regions of Goiás, which lends validity to the model in identifying the diverse contexts experienced by public service users. This representativeness is essential to ensure that the model's classifications take into consideration the needs of the entire population.

A graphical interface was developed to support the analysis of Excel and CSV files for local use by the management responsible for evaluations. However, it was also automated on the Goiás state server, being directly fed from the data warehouse, it is replicable. This opens up opportunities for the approach to be applied in other customer service models across Brazil, enabling a national expansion of the developed solution. The standardization of data

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

input processes and the automation of classification make the model to be a scalable tool, which can be adapted to different regional contexts and the specific demands of each locality.

To successfully implement an artificial intelligence program focused on sentiment analysis of comments, it is essential to start the process with clear and transparent communication with managers, ensuring their support and alignment with the initiative's goals. It is also crucial to inform the team that AI is not here to replace them, but rather to eliminate repetitive and monotonous tasks, allowing them to focus on more relevant and strategic activities. The goal is to significantly enhance management by transforming large volumes of data into clear and actionable insights. With tools like sentiment analysis and word cloud visualizations, it becomes possible to quickly identify patterns, emotions, and recurring themes in customer or employee feedback. This enables managers to understand, objectively and in real time, how people perceive products, services, or even the organizational climate. With this information in hand, decisions are no longer based on assumptions but grounded in concrete data, increasing assertiveness, anticipating problems, and creating space for continuous improvement.

Finally, the results obtained reinforce the impact of using sentiment classification algorithms in public management. By prioritizing negative comments as the model's main focus, it allowed for more precise identification of critical points in the services provided, serving as an important monitoring tool for managers to understand citizens' improvements demands in public services. In this way, the work contributed to the improvement of sentiment analysis techniques in the public services context and to the enhancement of the quality of services offered to the population.

Enhancing Open Data Findability: Fine-Tuning LLMs(T5) for Metadata Generation.

*Umair*Ahmed[a*], *Andrea*Polini[a]

[a]Dipartimento di Informatica, Universita di Camerino, Camerino, Italy, Emails: umair.ahmed@unicam.it, an-drea.polini@unicam.it, ORCIDs: 0000-0003-2260-2777, 0000-0002-2840-7561.

Submitted: 31 January 2025, Revised: 26 March 2025, Accepted: 21 April 2025, Published: 19 May 2025:

Abstract. Metadata is essential for improving the discoverability and findability of datasets. According to the European Data Portal (EDP), Europe's largest open data portal, keywords and categories alone contribute to 60 percent of a dataset's visibility. Given that datasets can have highly variable and complex contexts, we propose leveraging the power of Large Language Models (LLMs), specifically T5-small and T5-large, to generate these metadata. In our study, we used EDP as our case study. We obtained 60,000 datasets from EDP and undertook thorough data cleaning and transformation. This process yielded 3,131 datasets for keyword extraction and 2,790 datasets for category extraction, ready for model fine-tuning.

The base versions of T5-small and T5-large initially struggled to produce keywords that were representative of those generated by humans, resulting in F1 scores of only 0.0455 and 0.1051, respectively. However, fine-tuning significantly improved their performance, achieving an F1 score of 0.4538 for T5-small and 0.6085 for T5-large. A similar pattern was observed in category extraction. The base T5-small and T5-large models had F1 scores of only 0.1222 and 0.3326, respectively. In contrast, the fine-tuned models produced F1 scores of 0.6284 and 0.8322, respectively. Notably, T5-large produced keywords similar to those generated by humans in over 60% of cases, and its category predictions matched human-generated ones in over 80% of cases. This highlights the potential of using large language models (LLMs) for generating human-like metadata, thereby significantly enhancing data findability and usability across various applications.

1. Introduction

In the current data-driven world, there has been a significant increase in the volume and circulation of data. It has alerted stakeholders of its potential to be the new oil. Europe's data economy was estimated to be around €739 billion in 2020 (Van Loenen et al., 2021). Making this data open could lead to a more transparent and inclusive ecosystem. While its potential has already turned heads and a significant amount of data is open, its findability and discoverability across different portals still remain a challenge.

In this study we focus on the lack of quality metadata, that is one of the major causes of poor findability. Indeed, metadata definition is often overlooked by publishers when uploading a dataset. They are usually either unaware of the importance of metadata or more focused on the task of making the data open while ignoring the potential impact of having good metadata. It necessitates an alternate mechanism to fill in the metadata or recommend it to publishers, forming this study's basis. As the European Data Portal (EDP) (EU,

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

2025) is one of the largest open data portals, we use it as the case study for this research. There are several metadata attributes that enhance a dataset's visibility, including title, description, categories/themes, and keywords. However, according to the EDP, as shown in Table 1, keywords and categories/themes account for 60% of the overall findability score for datasets (EU, 2025). Apart from EDP, keywords and categories are considered to be the most essential elements in general findability. It motivates us to focus on the automated extraction of keywords and categories. By generating good-quality and relevant metadata, we can significantly improve the discoverability of these datasets.

Tab. 1 – European Data Portal Findability Score (EU, 2025)

Indicator	**Description**	**Metrics**	**Weight**
Keyword usage	Keywords directly support the search and thus increase the findability of the data dataset.	The system checks whether keywords are defined. The number of keywords has no impact on the score.	30
Categories	Categories help users to explore datasets thematically.	It is checked whether one or more categories are assigned to the dataset. The number of assigned categories has no impact on the score.	30
Geo search	Usage of spatial information would enable users in order to find the dataset with a geo-facetted search.	It is checked whether the property is set or not.	20
Time-based search	Usage of temporal information would enable users for a timely based facetted search.	It is checked whether the property is set or not.	20

Numerous AI methodologies exist to perform classification and concept extraction. However, this study focuses on leveraging Large Language Models (LLMs) to address the problem of missing/complete metadata, given their deep understanding of the context of texts. It mainly investigates the performance of T5-small and T5-large in generating keywords and categories for datasets within the EDP.

For this study, we extracted 60,000 datasets from EDP, each comprising metadata fields such as titles, descriptions, keywords, and categories. We filtered the data after a rigorous cleaning and transformation process to ensure consistency and relevance. The final dataset included 3,131 instances for keyword extraction and 2,790 instances for category extraction. We fine-tuned both T5 models on these datasets to generate high-quality, human-like metadata. For keywords, we evaluated model-generated outputs using ROUGE-1 and cosine similarity with a threshold of 0.5 to measure the semantic overlap with human-generated keywords. For categories, we performed a one-to-one matching between model-predicted and actual categories. We calculated precision, recall, and F1 scores to assess overall accuracy for both tasks.

The results of this study reflect the effectiveness of fine-tuning large language models (LLMs) for metadata generation. The fine-tuned Flan-T5-large model consistently outperformed T5-small and the base models in both keyword and category extraction tasks, achieving F1 scores of 0.6085 and 0.8322, respectively. These results highlight the significant potential of LLMs to improve metadata quality, address critical gaps in open data platforms, and enhance dataset findability and discoverability. While significant research is underway in the field of semantic search mechanisms due to the advent of large language models (LLMs), our proposal aims explicitly to enhance the searchability and discoverability of datasets that already exist in open data portals. The search mechanisms mostly rely on basic one-to-one matches.

In the subsequent sections, we present a detailed discussion of our study's related work, methodology, results, and implications of our study.

2. Related Works

The significance of metadata, particularly keywords and categories (tagging), in improving a resource's findability, discoverability, and accessibility is well documented. Although several studies have focused on meta-

data generation, minimal research specifically addresses AI's use for generating metadata of open datasets. Following studies have explored the problem of findability and metadata extraction in various domains and from different perspectives. Most of the explored studies employed traditional machine learning models for keyword extraction, while more recent studies also employed LLMs. One such study, RAKE, performs keyword extraction by identifying co-occurrence relationships between words in a document. Even if it is quite fast, it struggles with more semantic relations between texts (Rose et al., 2010). A more advanced method like YAKE!, an improvement on RAKE, employs additional local statistical features for unsupervised keyword extraction. It considers multiple features, including word frequency, co-occurrence, and position, to extract keywords more efficiently (Campos et al., 2020). Moreover, this particular method improves upon frequency-based methods by assigning a higher weight to words occurring often (Würsch et al., 2023). This study explores both machine learning (decision tree and kea) and deep learning (ANN and LSTM) models (Deng, 2024). Despite their effectiveness, traditional methods remain limited in extracting high-quality metadata, especially in cases where semantic understanding is essential.

While traditional methods have been quite robust, contemporary LLMs have paved the way for more semantically aware keyword extraction. For instance, LLM-TAKE utilizes theme-aware keyword extraction, leveraging LLMs to generate keywords that are contextually aware and capture contextual relations (Maragheh et al., 2023). Similarly, Lee et al. (2023) explored and employed a trained LLM, Galactica by Meta, to generate keywords for scientific literature. It showed significant improvements over traditional methods like RAKE and YAKE! (Lee et al., 2023). Purwar and Sundar (2023) use KeyBERT for keyword generation and GPT 3.5 for question answering about the context of the text (Purwar & Sundar, 2023). Ahmed et al. employed a hybrid of BERT, RAKE, TAKE, and TextRank (BRYT) to generate semantically aware keywords from dataset descriptions, which considered the best keywords from each model and reranked them to give the most optimal output (Ahmed et al., 2024)(Ahmed, 2023).

Beyond keyword extraction, category/theme tagging has also benefited from LLMs' ability to understand context, be semantically aware, and generalize across domains. Models like T5 (Raffel et al., 2020) and GPT-3 (Brown et al., 2020) have been fine-tuned for domain-specific metadata generation, including multi-label classification tasks for thematic tagging. For instance, li et al. explored hierarchical transformer models for multi-label text classification. It demonstrated their capability to understand semantic knowledge at different levels to classify the text into given categories (Li et al., 2022). Recent developments also emphasize the integration of multimodal data with LLMs for combined keyword extraction and annotation. Kathiriya et al. explored multimodal LLMs to enhance metadata tagging across datasets that include diverse information (Kathiriya et al., n.d.). Dai et al. also explored the potential of LLMs, particularly GPT-3.5, to replicate human-like behavior in various tasks (Dai et al., 2023). The integration of LLMs with multimodal data, as explored by Kathiriya et al. (2023), further demonstrates the potential of AI-driven approaches to enhance the discoverability of information across diverse platforms, such as e-commerce and data portals (Kathiriya et al., n.d.). Moreover, prompt-tuning and zero-shot capabilities of LLMs, such as OpenAI's GPT models, have made it possible to extract both keywords and thematic categories as multimodal efficiently. By combining supervised fine-tuning and techniques like few-shot learning, these models can address the dual challenge of keyword extraction and thematic tagging at the same time, making them invaluable for dataset-level metadata generation. However, they are significantly more expensive and might hallucinate answers (Ouyang et al., 2022).

3. Methodology

In today's information-driven world, open datasets can potentially solve real-world problems, whether they concern the economy, climate, governance, or health. However, for this to be realized, those datasets have to be findable, accessible, and usable. This notion shaped the basis of our research question: "How can we make vast amounts of data findable and discoverable?". Unfortunately, this vast amount of data, more often than not, hide in plain sight due to poor metadata, such as missing/misrepresentative keywords or missing/misclassified categories. Our goal in this study was to select a semantically capable AI agent, train it to thoroughly understand dataset descriptions, and generate accurate, representative metadata, much like an expert human curator might do.

To achieve this, we curated a methodology (reflected in Fig. 1 and Fig. 2) that involved gathering data, cleaning and refining it, selecting the AI model, designing clear instructions for AI (prompts), fine-tuning the model to

mimic an expert human curator, and evaluating it using the collected data. In the following sections, we provide insights into each step of the methodology.

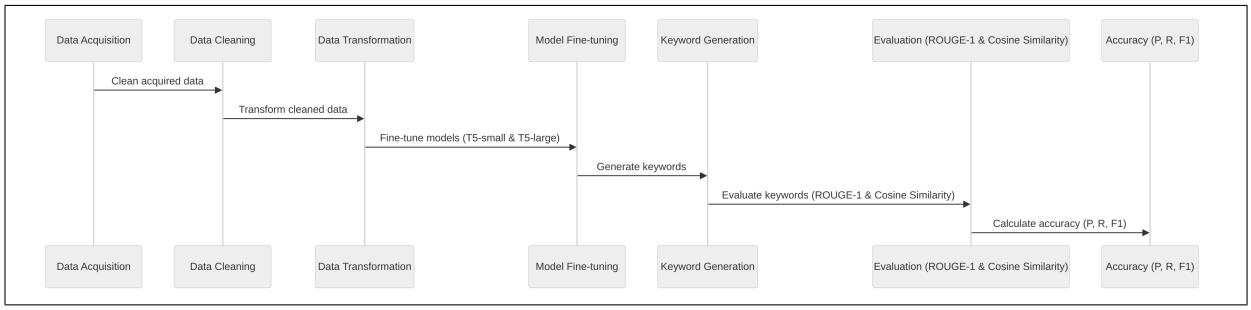

Fig. 1 – Diagram illustrating the key components of the keyword extraction

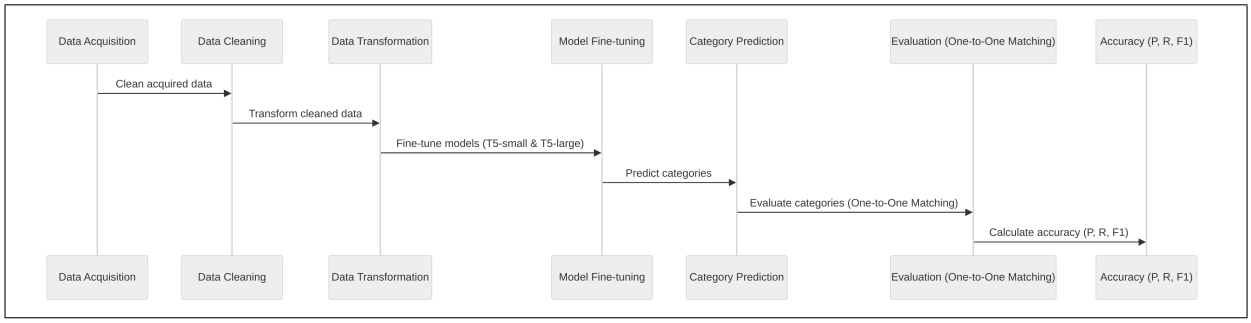

Fig. 2 – Diagram illustrating the key components of the category extraction

3.1. Data Collection and Preprocessing

The European Data Portal is one of the most significant open data initiatives, aggregating open data from EU states. We selected it as our use case and extracted 60000 datasets from it. These datasets were related to various sectors, such as environment, economy, health, and governance. Although there were significant amounts of extracted datasets, their quality was variable, which prompted the need for extensive data cleaning.

We aimed to curate two clean datasets for each task, necessitating task-specific data cleaning and transformation to ensure appropriate model fine-tuning.

3.1.1. Data Exploration and Initial Observations

Prior to data cleaning, we performed an exploratory analysis to understand it. The following observations were recorded and shaped our strategy towards data cleaning:

- **Inconsistent Metadata:** A significant amount of datasets had minimal or missing keywords and categories. Moreover, many of the keywords and categories present were not representative.
  - **keywords:** Many instances had repetitive or nonrepresentative long keywords. For instance, one of the datasets had 41 keywords and one of the keywords was 'From 25 to 34 years (current quarter)' which definitely hurts the chances of a dataset being findable
  - **Categories/Themes:** Several datasets had either missing categories or too many categories assigned to them. For instance, one of the datasets had the following six categories assigned to it: 'Economy and finance | Education, culture and sport | Government and public sector | Health | Population and society | Regions and cities'.
- **Noise in Descriptions:** Some descriptions contained garbage characters, HTML tags, just names of columns, or were too short to be considered for the AI model to extract metadata from. For instance, the following dataset description was too small to consider: 'Traffic signals in Copenhagen Municipality'

- **Multilingual Records:** Various descriptions were in different languages and had to be cleaned to keep the dataset consistent. For instance, the following description: 'Navly, ligne de navette autonome, électrique et sans conducteur au sud du quartier de la Confluence, le long de la Saône.'

These highlighted observations necessitated a more detailed cleaning of the data for efficient training and evaluation of the model.

3.1.2. Preparing the Keyword Extraction Dataset

In the keyword extraction task, we aimed to extract keywords that were relevant and concise. With that in mind, we performed the following data cleaning for it:

- **Language Filtering:** We filtered out non-English descriptions to maintain consistency in training the language models, as different languages in the prompt could confuse the model while training. For instance, a description in French could make it extract multilingual keywords.
- **Title Deduplication:** Using fuzzy matching, we eliminated datasets with titles that had more than 80% similarity to avoid redundancy. This ensured that the model was fine-tuned on a diverse range of examples.
- **HTML Tag Removal:** Some descriptions contained HTML tags, which we eliminated for better text preprocessing. It was essential because non-textual elements in the description could disrupt the model's capability.
- **Number of keywords:** We selected descriptions with 3 to 12 keywords (to cover variability), as the recommended range for optimal keyword searchability is between 5 and 10 (Pottier et al., 2023).
- **Keyword Length:** We excluded keywords with more than three words to eliminate overly complex or irrelevant terms.

After this cleaning and transformation process, we were left with **3,131 records**. These were split into training (80%), evaluation (10%), and testing (10%) sets.

3.1.3. Preparing the Category Extraction Dataset

This task required further data cleaning and transformation to make the categories consistent and meaningful for the model to learn from. These categories are essential for navigating through datasets in any data portal which made us prioritize uniformity and clarity in associations.

- **Redundant Categories:** Some datasets had the same categories with different links or texts assigned to them. We merged those categories into one. For instance: 'http://publications.europa.eu/resource/authority/data-theme/GOVE, https://data.gov.ie/Government'
- **Standard Category URL:** We removed the categories not pointing to the standard Category URL or corresponding to category list names. For instance: 'ncb3a7ce63a654bed8f47f82f30cedd96b7, ncb3a7ce63a654bed8f47f82f30cedd96b9'
- **URL to Names:** We converted URLs of categories into their category names to make the category extraction more meaningful for the user. For instance: 'http://publications.europa.eu/resource/authority/data-theme/ECON' was converted to 'Economy and finance'

This process yielded in a dataset of **2,790 records** for category extraction, similarly split into training (80%), evaluation (10%), and testing (10%) sets.

3.2. Model Selection: Why we chose T5

Choosing a model was a critical task, as it would affect all aspects of the study, be it accuracy, time, space, or finances. We chose T5 (Text-to-Text Transfer Transformer), designed by Google, because of its capability to understand semantic relations in the text while being a small model trainable with a modest amount of resources (Raffel et al., 2020). It puts the model in a unique position where it is not so large that it consumes

significant resources like GPT or LLaMA. Yet, it is also not too small to be unable to understand semantic relationships in the text. Moreover, it was designed to handle a wide array of tasks using a text-to-text approach. In our study, both inputs (descriptions) and outputs (keywords/categories) are in a textual format, making it ideal for these tasks given our compute resources. We employed two variants of T5, namely T5-small and T5-large. Following is a brief overview of the models' architecture.

- **T5-small:** It has 60 million parameters, with 6 encoder/decoder layers, a hidden size of 512, and 8 attention heads. This model is lightweight, resource-efficient, and suitable for low-resource environments, but it may underperform on complex tasks (Raffel et al., 2020).
- **T5-large:** It has 770 million parameters, with 24 encoder and decoder layers, a hidden size of 1024, and 16 attention heads. This model captures intricate patterns and generalizes well for complex tasks; however, it requires significant computational resources (Raffel et al., 2020).

Given various model sizes and limited resources, we wanted to explore the possibility of performing this task with the smallest model to consume minimal resources. This is indeed also needed to permit fast suggestions to the operator uploading the dataset. While T5-small provided faster training and inference, T5-large demonstrated superior performance, making it more suitable for capturing nuanced relationships in complex texts.

3.3. Fine-Tuning T5: Unlocking Task-Specific Precision

Similar to how students and researchers begin by exploring a wide array of subjects before narrowing their focus to specialize in one specific area, fine-tuning helps a language model become highly skilled at a specific task (Ohm, 2024). T5 also had been trained on a vast corpus of data, acquiring general language capabilities. However, the base versions of T5, without fine-tuning, performed inadequately on specific tasks. In our case, to generate human-like metadata, task-specific training was necessary. This led to our decision to fine-tune the model for improved performance.

We used our cleaned-out datasets to fine-tune T5 for our respective tasks. While fine-tuning, we carefully monitored the performance of models to avoid overfitting — a condition where the model starts memorizing data instead of understanding the underlying patterns, much like a student who memorizes the answers to a number of questions instead of understanding the concepts. We let it train for n epochs (iterations) until it showed any signs of overfitting, and then we stopped it. Early stoppage allowed us to determine the optimal number of epochs (training cycles). Following are the details for each task-specific fine-tuning:

3.3.1. Keywords

Flan-T5-small: As reflected in Table 2, we stopped fine-tuning at 17 epochs as the model showed signs of overfitting beyond this point. A learning rate of 4e-5 allowed the model to converge efficiently. Moreover, given the hardware resources and model, we kept the batch size at 8.

Flan-T5-large: This was the larger model, which was trained for 12 epochs before it also started overfitting. The slightly lower learning rate of 3e-5 ensured optimal convergence. It took more time due to its larger size compared to T5-small.

Model	Learning Rate	Batch Size (Train)	Batch Size (Eval)	Epochs	Weight Decay
Flan-T5-small	4e-5	8	8	17	0.02
Flan-T5-large	3e-5	8	8	12	0.02

Tab. 2 – Keyword Extraction: Finetuning configurations for T5-small and Flan-T5-large models

3.3.2. Categories

Flan-T5-small: As reflected in Table 3, we stopped fine-tuning at 8 epochs as the model showed signs of overfitting beyond this point. A learning rate of 4e-5 helped the model to converge efficiently. It took less time than the keyword extraction task because it ran for fewer epochs and had less complex task

Flan-T5-large: The larger model also stopped at 7 epochs, reducing from 12 epochs in keyword extraction because it started to reflect overfitting after that. Although it took significantly more time than T5-small to finetune but it was still less than T5-large for keyword extraction. It is reflected in Table 3.

Model	Learning Rate	Batch Size (Train)	Batch Size (Eval)	Epochs	Weight Decay
Flan-T5-small	4e-5	8	8	8	0.02
Flan-T5-large	3e-5	8	8	7	0.02

Tab. 3 – Catergory Extraction: Training configurations for T5-small and Flan-T5-large models

To perform the fine-tuning, we converted our datasets into T5-specific input prompts, as explained in the subsequent section.

3.3.3. Prompt Design

The efficiency of any LLM depends on well-curated prompts designed for a specific task (Alharbi et al., 2023; Maratsi et al., 2024) and a specific model. Conventionally, you provide an input textual prompt and labels as answers to those prompts. Following are prompts we crafted for each task:

Keyword Extraction

- **Input:** ["Generate 3 to 12 keywords for the following dataset description to improve its findability in a portal. Description: " + datasetDescription]
- **Labels:** Original Dataset Keywords

Category Extraction

- **Input:** ["From the following themes: 'Transport', 'Health', 'Government and public sector', 'Regions and cities', 'Environment', 'International issues', 'Justice, legal system and public safety', 'Energy', 'Education', 'culture and sport', 'Economy and finance', 'Population and society', 'Science and technology', predict the most relevant themes for this dataset description. Description: " + datasetDescription]
- **Labels:** Original Dataset Categories

These prompts were used to finetune T5 small and T5 large for both problems: keyword extraction and category extraction, respectively. The prompts were more concrete and simplistic yet gave enough context for T5 to be able to generate the the required output.

3.4. Model Evaluation

3.4.1. Keywords

We compared the generated keywords from the models with the original keywords using the following similarity metrics:

- **ROUGE-1 (Grusky, 2023):** ROUGE-1 assesses the similarity between the generated keywords and reference keywords by measuring the overlap of unigrams, which are single words.

$$ROUGE-1 = \frac{Numberofoverlappingunigrams}{Totalreferenceunigrams}$$

This metric offers a clear method to evaluate how much of the original content is represented by the generated keywords. We chose ROUGE-1 because it effectively measures direct word matches and is commonly used in tasks like text summarization and text generation.

- **Cosine Similarity (Gunawan et al., 2018):** It calculates the cosine of the angle between two vectors representing the generated and original keywords.

$$CosineSimilarity = \frac{\sum_{i=1}^{n} A_i \cdot B_i}{\sqrt{\sum_{i=1}^{n} A_i^2} \cdot \sqrt{\sum_{i=1}^{n} B_i^2}}$$

Cosine similarity is useful for estimating semantic similarity between words/sentences. This metric is commonly applied in information retrieval and semantic similarity tasks.

We calculated how many original (human-like) keywords were accurately predicted by the model. If 50% or more of the original keywords matched using either of the two metrics, we conventionally considered it a match for that row. We considered using both metrics to capture two-fold matching between keywords: unigram and semantic.

3.4.2. Categories

We compared the generated categories from the models with the original categories using one-to-one matching. The categories were predefined, and the predicted category was only one of those 13 categories, which made the matching simpler.

We calculated the models' accuracy after matching the predicted and original labels in both tasks. We used precision, recall, and F1 scores to estimate the model's accuracy, as reflected below:

- **Precision:** Precision measures the proportion of correctly predicted keywords/categories (matches) out of all the keywords/categories predicted by the model (Kumar & Gupta, 2015). It reflects how many generated keywords mirror keywords a human curator might choose. It is calculated as:

$$Precision = \frac{Number of Matches}{Total Predicted Keywords/Categories} (Kumar \& Gupta, 2015)$$

- **Recall:** Recall measures the proportion of correctly predicted keywords/categories (matches) out of all the original keywords/categories in the dataset (Kumar & Gupta, 2015). It is calculated as:

$$Recall = \frac{Number of Matches}{Total Original Keywords/Categories} (Kumar \& Gupta, 2015)$$

- **F1 Score:** The F1 score is the harmonic mean of precision and recall, balancing their contributions (Kumar & Gupta, 2015). It is calculated as:

$$F1Score = 2 \cdot \frac{Precision \cdot Recall}{Precision + Recall} (Kumar \& Gupta, 2015)$$

These metrics were calculated for all test datasets, comprehensively evaluating the model's ability to predict relevant and accurate metadata.

3.5. Machine Resources and Fine-Tuning Runtime

The fine-tuning process for both keyword and category extraction tasks was conducted on a machine with the following specifications:

- **CPU:** 8 Cores
- **RAM:** 64 GB
- **GPU:** NVIDIA A100

The fine-tuning runtimes for each model and task are summarized in Table 4.

These runtimes highlight the computational efficiency differences between Flan-T5-large and Flan-T5-small, with the latter requiring significantly less time due to its smaller size and fewer parameters.

Task	Model	Fine-Tuning Time (hh:mm:ss)
Keyword Extraction	Flan-T5-large	1:07:43
Keyword Extraction	Flan-T5-small	00:08:31
Category Extraction	Flan-T5-large	00:31:58
Category Extraction	Flan-T5-small	00:04:01

Tab. 4 – Fine-tuning runtimes for each model and task.

Results Overview

In this section, we aimed to evaluate how effectively fine-tuned LLMs can generate metadata—particularly keywords and categories—to improve the findability of the datasets. We focused on two models, namely T5-small and T5-large, and compared their performance before and after fine-tuning. This comparison reflected an apparent transformation. Fine-tuning the base models enabled them to shift from generating non-representative and unreliable metadata to generating effective metadata that closely resembled what a human curator might create. This section views these observations from the lens of metrics like precision, recall, F1 scores, and match rates.

Keyword Extraction

Keywords define the essence of any resource and allow users to understand the summary of the resource without navigating it. In this study, we employed T5-small and T5-large to generate the keywords for EDP datasets. Initially, T5-small and T5-large struggled with extracting keywords. Their base (non-finetuned) models generated keywords that were either inconsistent or irrelevant when compared to human-curated ones. They fell short in both matching algorithms, Rouge-1 and cosine similarity, with a minimum threshold of 50 percent. As reflected in (Table 5) and Fig 3, T5-small only generated keywords for 2 datasets that matched at least 50 percent with the human-labeled metadata, while T5-large only managed just three datasets at a similar threshold.

Match Percentage	T5-small (Base)	T5-small (Finetuned)	T5-large (Base)	T5-large (Finetuned)
$\geq 10\%$	36	220	82	271
$\geq 20\%$	15	206	51	258
$\geq 30\%$	9	189	25	245
$\geq 40\%$	7	148	14	220
$\geq 50\%$	2	139	3	207
$\geq 60\%$	2	126	1	195
$\geq 70\%$	0	89	0	133
$\geq 80\%$	0	62	0	115
$\geq 90\%$	0	45	0	89
$= 100\%$	0	45	0	88

Tab. 5 – Keyword Extraction: Match Percentages Across Models.

As demonstrated in (Table 6) and Fig 4, their performance was significantly weak across all key metrics. Precision, which reflects how many generated keywords were actually correct, was just 0.1093 for T5-small and 0.1919 for T5-large. Recall, which represents how well the model captured the full range of relevant keywords, was similarly low at 0.0287 for t5-small and 0.0724 for t5-large. Consequently, F1 scores, which balance precision and recall, were abysmal: 0.0455 for T5-small and 0.1051 for T5-large. These scores reflected the models' inability to understand the semantic nuances in dataset descriptions.

However, fine-tuning transformed their performance drastically, given it enhanced the model's understanding of the particular task of keyword extraction. Once fine-tuned, the T5-small model improved its match rate to 139 rows at the 50% threshold, while T5-large matched in 207 rows. It is reflected in (Table 5) and Fig 3.

As observed in (Table 6) and Fig 4, the precision of the fine-tuned T5-large model improved to 0.6423, and its recall increased to 0.5781, resulting in an F1 score of 0.6085. This meant that the model generated keywords relevant to the dataset descriptions over 60% of the time—comparable to human experts. This improvement

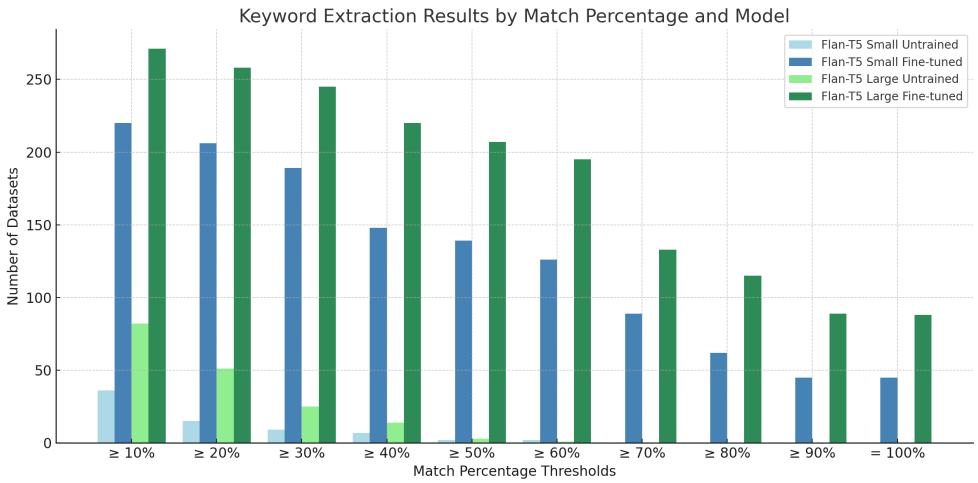

Fig. 3 – Match Percentages Across Models for Keyword Extraction.

Model	Precision	Recall	F1 Score
T5-large (Finetuned)	0.6423	0.5781	0.6085
T5-large (base)	0.1919	0.0724	0.1051
T5-small (Finetuned)	0.5227	0.4010	0.4538
T5-small (base)	0.1093	0.0287	0.0455

Tab. 6 – Keyword Extraction: Precision, Recall, and F1 Scores.

highlights how fine-tuned language models can significantly enhance metadata quality, ensuring that users can find the information they need even through basic keyword-driven searches.

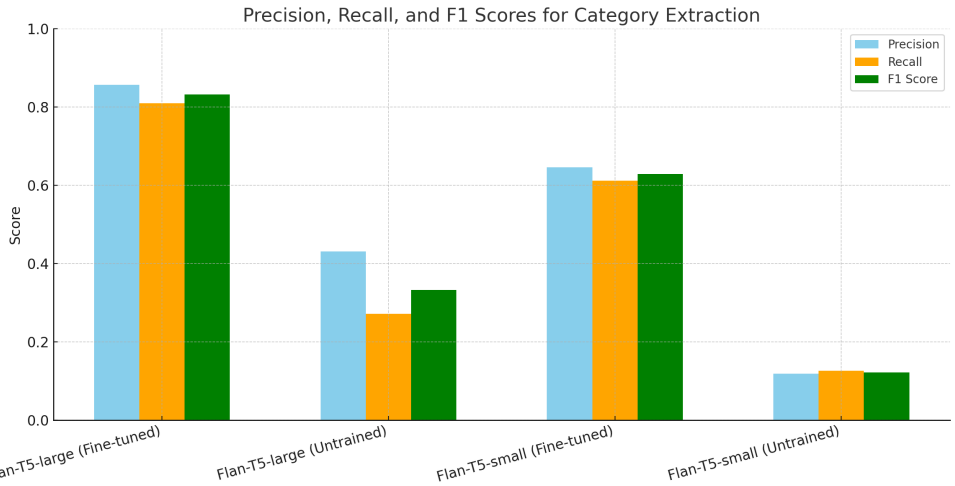

Fig. 4 – Precision, Recall, and F1 Scores for Keyword Extraction Models.

Category Extraction

Dataset themes/categories are essential for organizing datasets thematically, allowing users to navigate large data repositories more effectively. For category extraction as well, we employed T5-small and T5-large. Similar to keyword extraction, both base models performed poorly. As reflected in (Table 7) and Fig 5, T5-small had 223 rows where no category matches were found, while T5-large had 138 such rows. The number of rows with match percentages in the 75–100% range was also minimal, with only 30 matches for T5-small and 50 for T5-large. These results indicated that the models struggled to associate dataset descriptions with relevant categories due to a lack of understanding of semantic context.

Match Percentage	T5-small (Base)	T5-small (Finetuned)	T5-large (Base)	T5-large (Finetuned)
0%	223	100	138	44
1 – 25%	5	4	11	2
25 – 50%	20	22	79	14
50 – 75%	1	1	1	3
75 – 100%	30	152	50	216

Tab. 7 – Category Extraction: Match Percentages Across Models.

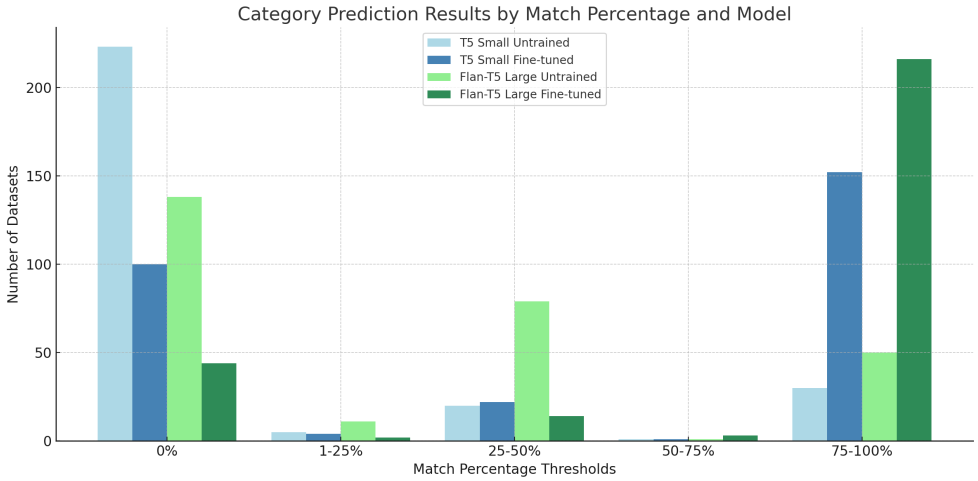

Fig. 5 – Match Percentages Across Models for Category Extraction.

Fine-tuning again led to significant improvements in match percentages. The number of rows with no matches was reduced to 100 for T5-small and 44 for T5-large. Meanwhile, rows with matches in the 75–100% range increased to 152 for T5-small and 216 for T5-large. This demonstrated a notable enhancement in the models' ability to align their predictions with human-curated categories.

Model	Precision	Recall	F1 Score
T5-large (Finetuned)	0.8566	0.8092	0.8322
T5-large (base)	0.4303	0.2710	0.3326
T5-small (Finetuned)	0.6459	0.6118	0.6284
T5-small (base)	0.1188	0.1258	0.1222

Tab. 8 – Category Extraction: Precision, Recall, and F1 Scores.

The improvement in match rates was further reflected in accuracy metrics. As observed in (Table 8) and Fig 6, the fine-tuned T5-small model achieved a precision of 0.6459, a recall of 0.6118, and an F1 score of 0.6284. The fine-tuned T5-large model demonstrated even better performance, with a precision of 0.8566, a recall of 0.8092, and an F1 score of 0.8322. These results highlight the effectiveness of fine-tuning in enabling models to interpret dataset descriptions better and predict relevant categories to enable more efficient thematic searches.

Fine-tuning consistently enhanced the performance of both models, with Flan-T5-large outperforming Flan-T5-small in both tasks. Figures 3 and 5 visually highlight the improvements in match percentages for each task, while Figures 4 and 6 emphasize the precision, recall, and F1 score advancements.

4. CONCLUSION AND FUTURE WORKS

This study explored the potential of fine-tuning Large Language Models (LLMs), specifically T5-small and Flan-T5-large, for generating keywords and categories for open datasets. While the base models struggled in both tasks, fine-tuning significantly improved their performance. Although both models demonstrated considerable improvements, T5-large consistently outperformed T5-small across all metrics.

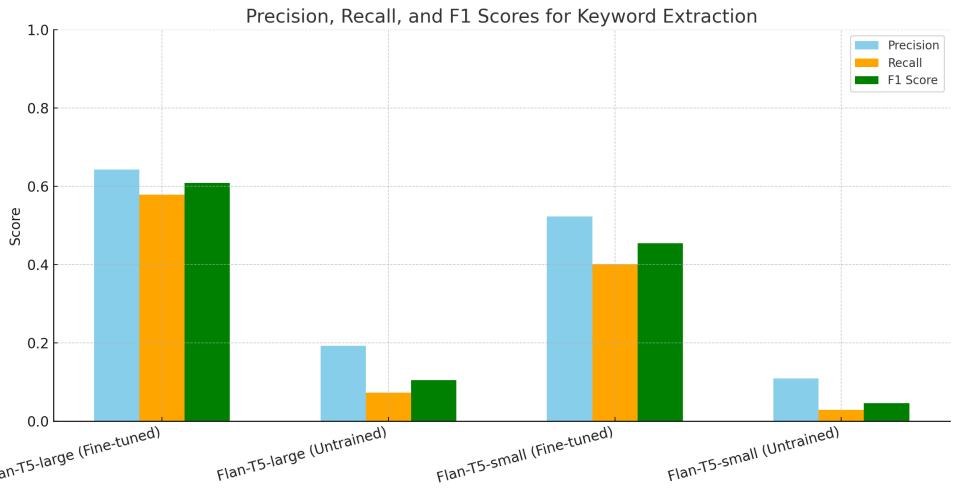

Fig. 6 – Precision, Recall, and F1 Scores for Category Extraction Models.

For keyword extraction, the base T5-small model achieved an F1 score of 0.0455, while T5-large had 0.1051. After fine-tuning, T5-small improved significantly with an F1 score of 0.4538, and T5-large achieved 0.6085, demonstrating its ability to generate human-like keywords that will improve dataset discoverability. Similarly, for category extraction, the base T5-small model had an F1 score of 0.1222, and T5-large scored 0.3326. With fine-tuning, T5-small improved its F1 score to 0.6284, while T5-large excelled with 0.8322, showcasing its capability to capture complex semantic relationships. These results highlight the potential of LLMs to generate metadata for missing or incomplete entries in open data portals, thereby improving dataset findability and discoverability.

Future work could further explore several avenues to enhance the scope and accuracy of metadata generation. Expanding the dataset to include more extensive and diverse examples could improve model generalizability and enable it to handle a wider range of contexts. Employing other large language models, such as GPT, LLaMA, and DeepSeek-R1, could significantly impact the study's accuracy and performance outcomes. Multilingual support would allow the models to generate metadata in multiple languages, catering to a broader audience. Additionally, integrating actual dataset samples or other metadata elements, such as titles, publishers, catalogs, or geographic information, as input features could improve prediction quality. Following keyword and category extraction, we want to generate the description using the dataset's contents. Another promising direction involves incorporating user feedback from data portal users and publishers, enabling iterative refinement of generated metadata to better align with user needs.

By addressing these areas, future studies can significantly contribute to a more accessible, interoperable, and user-friendly open data ecosystem.

Abstract. This study investigates challenges in ensuring data quality within Brazil's national educational database, the Sistema Gestão Presente (SGP), and proposes solutions. Reliable and integrated data systems are critical for evidence-based policymaking, particularly in education. The SGP, designed to centralize student attendance and enrollment data, faces issues such as inconsistent data entry, logical errors, and systemic reporting anomalies. To address these challenges, a data-driven methodology inspired by the DMAIC framework was implemented, focusing on defining problems, measuring and analyzing data inconsistencies, improving processes through tailored solutions, and monitoring outcomes for continuous quality assurance. Seven case studies illustrate the results of this approach. These include resolving inconsistent enrollment dates, limiting multiple active enrollments per student, and ensuring consistency between disenrollment justifications and active statuses. Further, systemic anomalies, such as inflated attendance rates and implausibly high class hours reported at state levels, were identified and corrected through validation rules, training initiatives, and auditing mechanisms. These interventions reduced data inconsistencies, enhanced reliability, and improved system usability. The findings demonstrate how integrating validation mechanisms, improving data entry workflows, and fostering stakeholder collaboration can address large-scale data challenges. By ensuring the quality and integrity of educational data, the SGP enables more accurate insights into attendance patterns, dropout rates, and program effectiveness. These improvements lay the foundation for robust evidence-based policies and equitable educational outcomes across Brazil, highlighting the transformative potential of data quality assurance for public sector decision-making.

Keywords. Data quality, interoperability, data integrity, public policies, education.
Research paper, DOI: https://doi.org/10.59490/dgo.2025.943

1. Introduction

The quality and integrity of educational data are foundational to developing evidence-based policies that drive meaningful improvements in education. This study explores the need for reliable educational data, focusing

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

on attendance records, and investigates common anomalies that can arise in large-scale datasets. Among the many data points collected in education systems, attendance data is a critical indicator of student engagement, resource allocation, and overall system performance. Accurate attendance records are more than just statistics. They tell how students interact with their learning environments and provide essential insights for shaping their futures. Without reliable data, policymakers risk basing decisions on flawed insights, leading to inefficiencies and missed opportunities for improving educational outcomes. Data reliability is paramount for fostering accountability and enabling informed decision-making (Jenkins & Duri, 2020).

This study draws on data from the *Sistema Gestão Presente* (SGP), a comprehensive database that tracks student attendance across Brazil, designed to integrate data from thousands of sub-national educational departments. The SGP is a critical tool for monitoring student engagement at a national level, providing detailed records of student attendance in classrooms across diverse educational settings. However, the scale and complexity of the SGP dataset bring unique challenges, such as data inconsistencies, varying collection methodologies, and discrepancies in reporting.

Data collection for large-scale educational systems often involves multiple stakeholders, including schools, districts, and state-level administrators. This decentralized approach creates unique challenges for interoperability, as data from various sources must be harmonized within a unified system. Differences in data formats, collection methods, and validation protocols can result in inconsistencies and errors that undermine the credibility of the entire dataset (Rocha et al., 2024).

Maintaining data quality goes beyond initial collection; it requires continuous verification throughout the data lifecycle. While validations at the point of entry are essential, they are insufficient to address the complexities of large and evolving datasets. A practical quality assurance framework must have ongoing monitoring, anomaly detection, and feedback mechanisms to identify and correct errors as they arise. These processes are crucial not only for maintaining the integrity of the data but also for building trust among the stakeholders who depend on it for informed decision-making (Redyuk et al., 2021; Taleb et al., 2021).

Reliable educational data, especially attendance records, is the backbone of effective policymaking. However, collecting accurate data on a nationwide scale is no simple task(Queiroga et al., 2024). Schools, districts, and state systems often use varied methods, making consolidating information into a single, coherent dataset challenging. By addressing these challenges and building systems that ensure data consistency, trustworthiness, and ease of integration, we can empower educators and policymakers with the insights needed to create impactful, student-focused policies and initiatives.

The present paper describes how data inconsistencies inside SGP were dealt with by adopting a data-driven approach to redesign the system based on post-implementation analysis and enhancements. The remainder of the paper is structured as follows. Section 2 describes the work focusing on data interoperability problems, while section 3 presents the educational context of SGP. Section 4 illustrates the methodology followed during the development of SGP to ensure data quality and integrity while describing the most important actors and stakeholders involved. Section 5 describes seven study cases to illustrate the data inconsistencies in the SGP and how they were resolved by adopting the presented methodology. Section 6 discusses the findings from the work, and section 7 concludes the paper.

2. Related Work

Data interoperability is a fundamental need in the public sector, encompassing different areas of governmental activity. As highlighted by Restrepo-Carmona et al., 2024, interoperability and the systematization of public databases can enhance transparency, accountability, and efficiency in the management of public funds. These examples demonstrate how interoperability transcends sectors, acting as a crucial pillar for the modernization and effectiveness of public administration.

Another relevant work on the importance of interoperability in the governmental context is Tavares and Bitencourt, 2022, which explores the relationship between interoperability and public policy evaluation within the scope of digital governance. Despite its significance, the implementation of interoperability faces significant barriers, such as the need for investments in technological infrastructure, personnel training, and cultural shifts within public institutions. These last two points, in particular, are directly tied to the success of data

usage, as public agents play a central role throughout the data lifecycle—from initial entry to final interpretation for decision-making. However, as noted by various studies in this field, the challenges faced are global and structural. The survey by Restrepo-Carmona et al., 2024, when analyzing the feasibility of interoperability in Latin American governments, identified recurring difficulties such as limited access to public data, lack of standardization, and the need for greater interinstitutional collaboration to integrate data efficiently. Additionally, infrastructure, governance, and organizational culture issues exacerbate these challenges.

Moving into the health sector, interoperability is also recognized as a critical factor for the reliability and quality of data. As noted by D'Amore et al., 2018, processes and tools aimed at cataloging and enhancing clinical data quality underscore the importance of well-defined standards. Similarly, Valdés and Lecaros, 2024 proposes necessary actions for creating biobanks in the Latin American context, aiming to strengthen research and produce high-quality scientific evidence on a global scale.

Interoperability plays a crucial role in Brazil's healthcare system, particularly for data quality and system integration. According to the systematic review by (Barbalho et al., 2022), 78.58% of analyzed studies highlight interoperability between systems as essential for improving patient care. Their research identified 31 national health information systems operating in primary care between 2013-2018, with significant fragmentation challenges. This fragmentation became more evident in the implementation of e-SUS Primary Care Strategy, as shown by (Coelho Neto et al., 2021), where only 12 of 31 systems achieved complete integration with e-SUS interfaces. In comparison, 15 systems showed no integration at all. The study revealed a stark disparity between systems managed by different government departments - notably between the Health Care Secretariat (SAS) and Health Surveillance Secretariat (SVS), where SVS systems showed minimal integration despite having similar numbers of systems in use. Similarly, (Vasques et al., 2024) propose a maturity framework for evaluating interoperability in Brazilian healthcare institutions, noting that despite SUS protocols established in 2011 to coordinate information from over 6,000 healthcare providers, private institutions often develop independent systems that minimize contribution to the broader Brazilian health network. This fragmentation persists despite initiatives like the National Health Data Network (RNDS), which impact data quality and limit the potential for integrated healthcare delivery.

Entering the educational domain, several studies explore interoperability and data adequacy for implementing and improving educational systems. For instance, Macedo de Andrade et al., 2022 evaluates a program's impact on encouraging educational data use by school actors. This study employed a quasi-experimental Differences-in-Differences (DiD) model to analyze the effects of the *Escolas em Foco* program. The methodology combines advanced statistical techniques to measure the program's impact while addressing the importance of data interoperability to enhance student learning. The analysis was conducted using various datasets, highlighting how the effective use of such information can support improvements in school performance.

The work of BOZ and SIMSEK, 2022, the interoperability of information systems within Turkey's Ministry of National Education (MoNE) is explored in detail. The article emphasizes that MoNE is the country's largest public institution, serving 18 million students and employing over one million teachers. To manage this robust structure, the ministry operates several information systems. During the study, metrics were identified to evaluate interoperability and strategies to improve intra-system communication. The work stresses that a stronger correlation between data is essential for more in-depth analyses, promoting advancements in the use of educational information.

In the Brazilian context, Queiroga et al., 2024 addresses the integration of the SAEB (National System of Basic Education Evaluation) and School Census databases. This study connects information about student performance and school conditions, enabling comprehensive analyses and identifying factors that impact educational equity in Brazil. The integration of these databases allowed researchers to go beyond isolated analyses, generating deeper *insights* into the relationships between school infrastructure and educational outcomes. The study reinforces the importance of reliable and interconnected data to provide a current overview and support public policies to improve Brazilian education.

Once the importance of data interoperability has been analyzed, data quality is another crucial factor for using these data. The study by Wijayanti et al., 2018 evaluates data quality in higher education, focusing on the Statistics Institute of Indonesia. This study used a quantitative approach to measure data quality, followed by a qualitative analysis of the results. Direct queries in SQL (Structured Query Language) were conducted in the integrated information system database. The evaluation revealed that the data quality at the Statistics Insti-

tute does not meet governmental requirements. Observing the completeness pillar, only 21.15% of business rules were met, and regarding validity, 57.90% of business rules were fulfilled, with issues found related to inconsistent data formats and types.

To solve the same problem of ensuring data quality in integrating university data, the study at Universitas Amikom Purwokerto Wahid et al., 2024 implemented a data warehouse. This data warehouse meets reporting requirements and promotes a culture of high-quality data management, where data is accessible, accurate, and useful for decision-making and strategic planning. Additionally, Du, 2021 described a model that seeks to define a theoretical and methodological framework for classifying, collecting, analyzing, and evaluating educational data quality, aiming to improve the management and utilization of these data. The study addresses the importance of a data quality management system in universities, encompassing quality assurance, process management, and data quality evaluation. The proposed model also emphasizes the need for a data quality evaluation system to ensure that collected data is accurate and complete. Although more focused on academic systems, these examples highlight the importance of data quality in connected contexts, demonstrating that efforts must be systematic and continuous to ensure the accurate and correct use of these data.

3. Educational context - The Sistema Gestão Presente (SGP)

The *Sistema Gestão Presente* (SGP)[1] is a new tool developed by Brazil's Ministry of Education (MEC) to enable comprehensive monitoring of students in basic education. This system is designed to centralize student enrollment and attendance tracking information, providing a sustainable and integrated platform for educational networks to submit data. Its implementation aims to streamline data management processes while enhancing accessibility and reliability across the education sector.

To accommodate the diverse realities of educational networks, the SGP allows for two formats of information submission: through APIs for educational networks with integrated systems and via data spreadsheets for those lacking advanced technological infrastructure. Figure 1 illustrates the data flow and integration within the SGP, highlighting its role in managing student data for Brazil's educational networks.

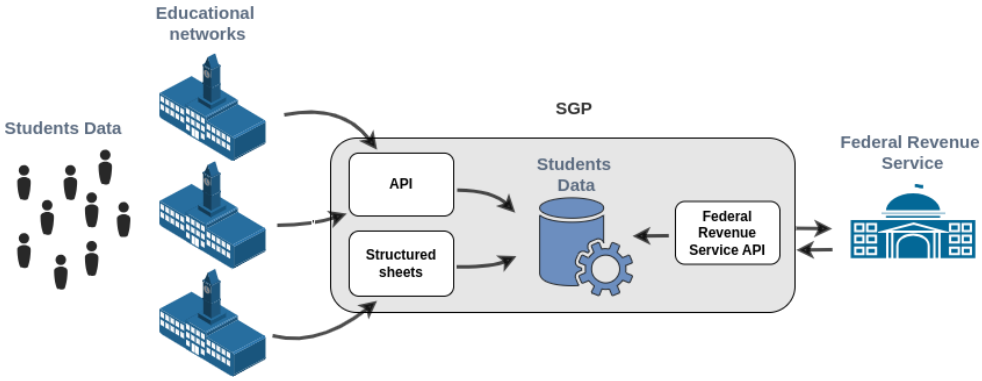

Fig. 1 – Sistema Gestão Presente.

The figure shows that the process begins with student data collected from schools across various educational networks. This data is transmitted to the SGP via structured spreadsheets or an API, depending on the technological capabilities of the institutions. Once in the SGP, the student data is stored in a centralized database, which can be processed and utilized. The system also integrates with the Federal Revenue Service through an API, enabling a two-way data exchange to support compliance, verification, and analysis needs.

This flexibility aims to enhance the system's reach and efficiency, ensuring that schools with robust systems and those with more limited resources can participate inclusively. With the consolidated database, studies can be conducted, and techniques can be applied to identify patterns and generate alerts about critical issues such as school dropout rates, student attendance patterns, or abrupt changes in attendance behavior. For instance, students with historically high attendance rates who suddenly show significant declines may indicate situations requiring closer monitoring by the school. This oversight allows for proactive interventions to address

[1] https://gestaopresente.mec.gov.br/

problems and promote student retention in the school environment (Macarini et al., 2020; Queiroga et al., 2022).

Implementing a system to support educational management in a country with continental dimensions, such as Brazil, is a significant challenge. In 2023, the National Institute for Educational Studies and Research Anísio Teixeira. (INEP) reported 47.3 million enrollments distributed across 178,500 educational entities in BrazilBrasil. Instituto Nacional de Estudos e Pesquisas Educacionais Anísio Teixeira (Inep), 2024, covering the entire national territory. Given the magnitude of this challenge, obstacles related to integrating various education networks are expected, considering their specific educational characteristics, such as differences in the number of school days, workloads, and regional particularities. These challenges were reflected in the data entered during the system's initial months of use. Errors or inconsistencies were identified, highlighting initial difficulties in adaptation by educational institutions.

The following section will address the anomalies detected and reported during this period, aiming to highlight the actions taken to improve the quality and accuracy of the data entered into the system.

4. Methodology for data quality assurance

This section describes the methodology currently followed by the SGP team to ensure the quality and integrity of data inside the system. Subsection 4.1 describes the main actors involved in this process, and 4.2 depicts the different steps followed during the process.

4.1. Working teams and stakeholders

Leading a project of great significance, such as the development and maintenance of the SGP, requires the integrated effort of multidisciplinary teams performing different roles within the organizational structure. This collaboration is essential for the system to meet the complex demands of the Brazilian educational context. At the project's core is project management, tasked with planning, coordinating, and ensuring the completion of each stage within the established deadlines and objectives while adapting to demands arising from interactions with external stakeholders. Developers, in turn, are responsible for implementing technical features, ensuring system robustness, user interface efficiency, database integrity, and the continuous refinement of business rules. Simultaneously, the data quality team monitors and validates the consistency and integrity of the data, ensuring its reliability for internal and external applications, such as future studies and analyses.

Additionally, the team focuses on the public policy perspective and strategically aligns project activities with societal priorities. This team works to maximize the system's impact, manage external demands, prepare manuals, organize training sessions, and mediate potential conflicts. Collaboration with external stakeholders is equally indispensable. The Ministry of Education, as the central coordinator, sets strategic guidelines and ensures alignment with national public policies. Meanwhile, state and municipal education departments are critical in implementing the system locally. They act as a bridge between the SGP and educational institutions, providing data, offering initial support, and serving as schools' first point of contact. Figure 2 depicts the most important actors involved in the process of ensure data quality inside SGP.

This integration between internal and external teams ensures that the SGP operates efficiently and is aligned with its users' real needs. As a result, the system directly contributes to quality educational management that is equitable and responsive to regional and national challenges.

4.2. Workflow

The methodology for data quality assurance follows a data-driven approach to problem-solving and optimization with a similar structure and purpose of lean DMAIC (Define, Measure, Analyze, Improve, Control) Six Sigma framework (Srinivasan et al., 2016). The process begins with problem definition ("Define" phase in DMAIC), focusing on clarifying hypotheses and research questions to set the foundation for analysis. In the design and prototyping phase ("Measure" and "Analyze" stages from DMAIC), data is systematically examined using statistical methods, machine learning, and visualization to identify and understand anomalies. The implementation phase ("Improve" phase from DMAIC) translates analytical findings into actionable solutions such as new business rules, training, and auditing to resolve identified issues. Lastly, the evaluation

Fig. 2 – Actors involved on SGP's data quality assurance.

and learning phase mirrors the "Control" phase, emphasizing monitoring implemented solutions, ensuring their effectiveness, and capturing insights for continuous improvement. Figure 3 gives an overall view of the methodology cycle and its actors.

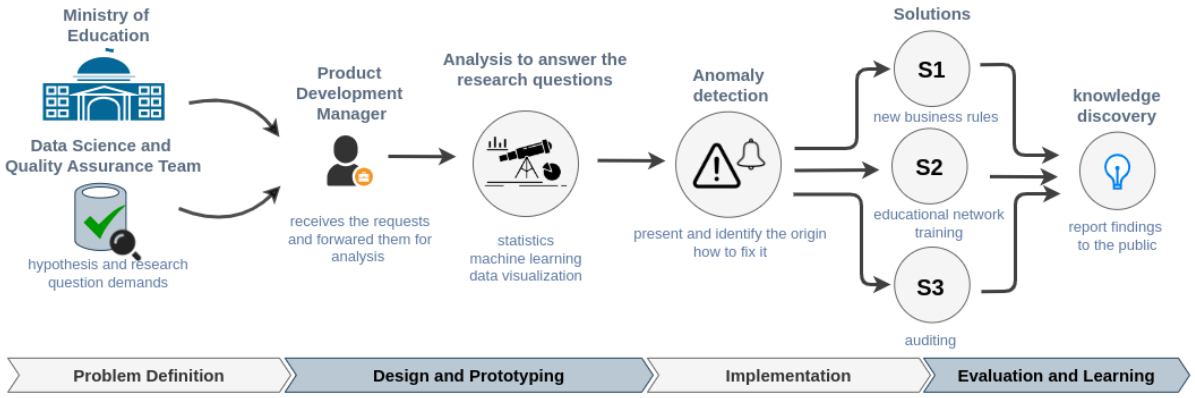

Fig. 3 – Overview of the data quality assurance process.

The figure shows that the process starts with the Ministry of Education or other stakeholders submitting hypotheses and research questions to the Data Science and Quality Assurance Team. The **problem definition** phase identifies and categorizes any inconsistencies in the data. This includes raising concerns and forming hypotheses to address incorrect data inputs or calculation errors. It's also a collaborative process involving stakeholders in understanding the scope and root causes of the problems entirely. The Product Development Manager plays a key role here, providing a bridge to ensure these issues are forwarded for deeper analysis. At this stage, the data is reviewed in detail to uncover patterns, outliers, and areas that need further investigation. This analysis lays the groundwork for the next steps and relies on technical expertise and a strong understanding of the educational context. From this work, two main types of hypotheses typically emerge:

- Team-Driven Hypotheses: These are based on patterns, anomalies, or inconsistencies uncovered through internal analysis.
- Externally Requested Hypotheses: These come from higher-level teams or the Ministry of Education (MEC) and address specific institutional priorities.

Once the hypotheses are formed, they are critically analyzed to ensure relevance and impact. This involves combining technical knowledge with an understanding of educational data and business rules, ensuring the investigations are well-targeted and aligned with the broader goals.

Data is then analyzed in the **design and prototyping** phase to address the research questions. Here, some techniques are used, such as statistical methods (quantitatively measuring and evaluating data), machine

learning (to detect more complex patterns or anomalies that are challenging to identify manually), and data visualization techniques (that assist in clearly and comprehensively communicating findings). Next, anomalies are identified, their causes traced, and potential solutions proposed. Tailored solutions are developed for each specific case. For example, new business rules are prototyped and tested on subsets of data, while training programs and audit strategies are designed iteratively to incorporate feedback from stakeholders.

The **implementation phase** focuses on implementing and deploying these solutions incrementally to minimize disruptions. Business rules were implemented in the system with automated validation, training sessions were delivered to users, and auditing processes were institutionalized to ensure ongoing data integrity. Three main types of outcomes have already been implemented according to the nature of each issue. These solutions included:

1. (S1) creation of new business rules within SGP - addressing scenarios where inconsistencies required new rules to be implemented at the system level to prevent similar issues in the future;
2. (S2) Training within the educational network - Cases involving manual input or network-related errors were mitigated through user training programs aimed at reducing future occurrences and
3. (S3) Data Auditing - Recommendations to the managers and government stakeholders to audit inconsistencies that were not resolved to ensure data reliability and integrity

Finally, the process concludes with **evaluation and learning**, where the outcomes of the implemented solutions are evaluated. Metrics such as the inconsistencies of anomalies, user feedback, and system performance are analyzed to measure the effectiveness of the interventions. Lessons learned are documented to refine future processes and ensure continuous improvement and shared publicly to foster knowledge discovery.

5. Case studies

To illustrate the methodology presented in the previous section, we present seven cases developed for eight months related to the data quality assurance process inside SGP. Each case has particularities that help to understand the nuances and complexities of data quality assurance inside a national educational system that receives information from all nationwide educational networks. As this process is cycled and is still under development, some solutions for specific cases are presented as suggestions for implementation and still need further evaluation.

5.1. Case 1: Inconsistent Enrollment Dates

Problem Definition: Inconsistent start dates were observed in the student's enrollment data. These inconsistencies suggest incorrect data entry, which can skew analysis when dates are used as filters or reference points for decision-making. To identify the scope of the problem, we executed a query that excluded the *starting date* condition, capturing all enrollment records regardless of their start dates. The analysis revealed a range of anomalous start years, from as early as 1900 (implying a 125-year-old high school student) to as late as 2029 (suggesting enrollment 4 years into the future). The most frequent inconsistencies were found in the years immediately preceding 2024. For example, 382,221 enrollments were recorded in 2022 and 153,407 in 2023. Outlier years, such as 1900, 1985, and 2029, also appeared in the dataset but with minimal occurrences (one enrollment each). Other years, such as 2016 (222 enrollments), 2018 (563 enrollments), and 2021 (3,659 enrollments), suggested a gradual increase in data reporting errors over time. These inconsistencies likely resulted from manual data entry errors or the lack of validation rules to ensure accurate recording of start dates. It is important to highlight that SGP is dealing with information from students enrolled in high school education, so dates such as 2016 or 1018 are considered not coherent with the expected date ranges.

Design and Prototyping: To address this issue, we proposed implementing validation rules to restrict start dates to a predefined range, with the current year as the last valid year for enrollment records. A prototype validation mechanism was designed to flag and reject entries with start dates outside the acceptable range during data input. This prototype was tested on a subset of historical data to evaluate its effectiveness and to identify potential edge cases, such as valid future or historical enrollments. In addition to technical solutions, systemic measures were proposed to minimize recurring errors. Training sessions are suggested to be developed for data entry staff to emphasize the importance of accurate data recording and to reduce manual errors.

Furthermore, a reporting dashboard was designed to highlight anomalous dates, enabling administrators to review and correct outliers in real-time.

Implementation: The validation mechanism was implemented in the application layer, and the date entry interface was updated with a date picker that restricted inputs to valid years, such as 2024. The team suggested guidelines explaining the validation rules for stakeholders to ensure a smooth transition. Additionally, historical data containing invalid start dates was retrospectively cleaned, with corrections prioritized for the most critical discrepancies. This combination of preventive measures and corrective actions ensured a robust implementation.

Evaluation and Learning: The solution's success is evaluated using several metrics. These include monitoring the reduction of invalid start dates in new records and assessing the efficiency of the reporting dashboard in flagging and correcting errors. User feedback is also being collected to evaluate the usability of the updated date entry interface and the clarity of the validation rules. The findings from this case underscore the importance of integrating validation mechanisms into data entry processes to improve overall data quality. The lessons learned are applied to other system areas with similar data validation challenges. These iterative improvements demonstrate a commitment to maintaining accurate and reliable data for analysis and decision-making.

5.2. Case 2: Multiple Active Enrollments for a Student

Problem Definition: After defining the criteria for an active enrollment, we identified cases where individuals had multiple active enrollments associated with their ID. While some instances of dual active enrollments are expected and valid, such as students simultaneously attending regular and technical schools, other cases raised concerns. Specifically, we focused on individuals with more than two active enrollments, which deviates from the expected norm. Our analysis revealed 138,747 individuals with more than two active enrollments at the time of the query. The presence of such anomalies indicates potential issues within the system, including errors in the registration process that allow duplicate or conflicting records, the absence of validation mechanisms to limit the number of active enrollments per individual, or possible misuse of the system—whether intentional or unintentional—resulting in inflated enrollment counts.

Design and Prototyping: To address this issue, we proposed implementing system-level validations to restrict the number of active enrollments associated with a single student ID to a maximum of two, accounting for valid scenarios such as simultaneous enrollment in regular and technical schools. A prototype validation rule was designed and tested on historical data to identify and flag records exceeding the defined threshold. In addition to this technical solution, we developed guidelines to clarify the conditions under which dual enrollments are permissible, ensuring alignment with institutional policies. These guidelines were shared with stakeholders to understand legitimate enrollment scenarios better and standardize data entry practices.

Implementation: The validation mechanism was integrated into the enrollment system to prevent the creation of new records that exceed the maximum allowable number of active enrollments—this involved frontend restrictions during the registration process and backend validations at the database level. A cleanup process was initiated for existing records to address individuals flagged with more than two active enrollments. This included engaging with educational institutions to verify and resolve duplicate or conflicting records. Training sessions were conducted for registration staff to support these efforts, emphasizing the importance of adhering to the validation rules and accurately categorizing dual enrollments. A reporting mechanism was also introduced to monitor new instances of multiple active enrollments, allowing for continuous oversight and prompt resolution of anomalies.

Evaluation and Learning: The success of the implemented solution is being evaluated through a reduction in the number of individuals with more than two active enrollments in subsequent data analyses. Additionally, the reporting mechanism tracks compliance with the validation rules and detects any remaining anomalies in real time. Feedback from registration staff and institutional stakeholders is being collected to assess the guidelines' clarity and the usability of the system improvements. This case highlights the importance of establishing precise validation mechanisms and robust monitoring processes to maintain data integrity. The insights gained from addressing this issue are applied to other system areas to prevent similar anomalies and ensure that the data accurately reflects real-world conditions.

5.3. Case 3: Enrollments with Justification for Disenrollment and Active Status

Problem Definition: In the enrollments table, the column `co_tipo_justificativa_desmatricula` records the reason for disenrollment. This field only contains a value if the enrollment is deactivated. However, our analysis identified cases where enrollments were simultaneously marked as active (`st_matricula_ativa = true`) and had a justification for disenrollment recorded. At the time of analysis, 26,106 enrollments exhibited this inconsistency. This issue suggests potential data entry or synchronization errors within the system. The inconsistencies likely result from incorrect updates to the enrollment status, where records remain active despite a justification for disenrollment being provided. Other possible causes include miscommunication between system modules responsible for managing enrollment statuses and disenrollment reasons and the lack of validation checks to prevent conflicting information in these fields during data entry. This inconsistency affects data reliability, particularly in metrics that accurately report active versus inactive enrollments and analyze disenrollment trends, which rely on precisely categorizing enrollment statuses.

Design and Prototyping: To address this issue, we proposed implementing validation rules to ensure that a justification for disenrollment can only be recorded if the enrollment status is marked as inactive. These rules were designed to operate at both the application and database levels to prevent conflicting information from being entered. A prototype validation mechanism was developed and tested on historical data to identify the extent of the issue and ensure that the rules functioned correctly. In addition to the validation rules, we proposed reviewing and redesigning the data entry workflows to reduce the likelihood of errors during status updates. This included automating clearing disenrollment justifications when enrollment is reactivated and enhancing system logs to capture changes to the enrollment status and associated justification fields.

Implementation: The validation mechanism was implemented to enforce consistency between the enrollment status and the justification for disenrollment fields. In the application layer, updates to the status field were synchronized with the justification field, ensuring that conflicting values could not be saved. At the database level, constraints were added to restrict the recording of a justification for disenrollment to inactive enrollments only. A system-wide data cleanup was performed to resolve existing inconsistencies. This involved reviewing the 26,106 flagged records and correcting them either by deactivating the enrollment or clearing the justification field, depending on the circumstances. Registration staff is also advised to be provided with guidelines detailing the correct process for handling enrollment status updates to ensure compliance with the new rules.

Evaluation and Learning: The solution's effectiveness is evaluated by continuously monitoring new enrollment records to ensure no further inconsistencies occur. Metrics include the number of new flagged records, the accuracy of active versus inactive enrollment reports, and the consistency of disenrollment trend analyses. Feedback from system users and administrators is suggested to be collected to assess the updated workflows' usability and the clarity of the validation rules. This case highlights the importance of validation mechanisms and system automation in maintaining data integrity.

5.4. Case 4: Analysis on the Application of 100% Attendances at the State Level

Problem Definition: Building upon the resolution of fundamental data inconsistencies, we expanded our analysis to investigate more complex anomalies, focusing specifically on the accuracy of attendance reporting at the state level. The aim was to assess whether all states correctly reported student attendance data and identify potential patterns or inconsistencies in applying 100% attendance rates. To achieve this, we calculated the percentage of full attendances relative to the total informed attendances for each State and month. This analysis enabled us to identify the State with the highest rate of full attendance across the analyzed period. The results revealed that State A reported the highest rate of full attendance in July 2024, with 104,937 enrollments (out of 140,859 informed enrollments) marked as having 100% attendance. This corresponded to a rate of 74.5%, the highest among all states during this timeframe. Such high rates of attendance of 100% could indicate genuine trends of high attendance, potentially reflecting efficient educational policies or practices. However, they could also result from overreporting or inaccuracies in data submission by institutions, raising questions about the reliability of attendance reporting.

Design and Prototyping: To investigate the validity of these findings, we designed an analysis framework to detect potential overreporting patterns and validate attendance data at the state level. This involved cross-referencing attendance data with other indicators, such as dropout rates and institutional capacity, to evaluate

whether the reported rates of 100% attendance were consistent with different metrics. Prototypes of visual dashboards were developed to present the attendance data in an accessible format, highlighting states and months with unusually high rates of full attendance. These dashboards allowed stakeholders to identify and investigate potential anomalies quickly.

Evaluation and Learning: The evaluation phase focused on monitoring flagged cases of potential overreporting and assessing the impact of the new reporting guidelines on attendance data quality. Metrics such as the number of flagged anomalies, feedback from state administrators, and improvements in attendance consistency were used to evaluate the effectiveness of the implemented measures. This case underscores the importance of cross-referencing attendance data with other indicators to ensure reliability. The findings have provided valuable insights into attendance reporting practices at the state level and have informed the development of additional validation mechanisms to maintain data integrity in future analyses.

5.5. Case 5: Hours Studied Greater than Hours Offered

Problem Definition: During an exploratory data analysis of the database, an inconsistency was identified where the reported hours studied exceeded the number of hours offered. This issue undermines the data's reliability, which could affect decision-making processes and policy outcomes. Queries were executed to identify the scope of the problem, and inconsistencies were flagged across three months. It is important to highlight that both information (hours studied and hours offered) are reported from the same source (educational network).

- In February 2024, there were 7,119 enrollments in State A, primarily in State schools, where the hours studied were greater than those offered.
- In March 2024, a similar issue was detected in State B, with 15 enrollments, all in State schools.
- By April 2024, 106 enrollments in State C were identified with the same inconsistency, predominantly in Federal schools.

The root causes of this issue likely include manual data entry errors leading to overreported hours studied, miscommunication between system modules responsible for calculating hours, and potential discrepancies in data aggregation processes at the institutional or regional level. The inconsistencies were reported to the product owner to address this issue, who prioritized a solution to mitigate its impact and ensure data consistency.

Design and Prototyping: The proposed solution involved implementing a business rule to prevent hours studied from exceeding hours offered. This rule was designed to operate at the database level, integrating validation mechanisms to stop invalid entries during data input and flagging existing anomalies for manual review. In addition to the technical solution, measures were proposed to address systemic issues, such as improved training for staff responsible for data entry and introducing auditing processes to monitor data integrity, particularly in regions with a high incidence of anomalies.

Implementation: The business rule deployment was planned carefully to minimize disruption. The rule was integrated into the application layer (via form validation) and the database (using triggers or constraints). Users and stakeholders were informed about the change, and guidelines were provided to ensure smooth adoption. A correction strategy was devised to address existing anomalies, prioritizing regions and school types most affected by the issue.

Evaluation and Learning: The success of the implementation is being measured through the reduction of inconsistencies over subsequent months and the Frequency and distribution of rule triggers. It is also suggested that feedback be collected from users and administrators regarding the rule's usability and effectiveness.

5.6. Case 6: Enrollments by State with More than 300 Studied Class Hours

Problem Definition: In our analysis, we identified cases where students were reported to study more than 300 class hours within a month. This threshold was selected as an inconsistency, representing an average of over 10 hours of study per day — an unlikely scenario given standard academic schedules and considering a maximum of 22 days per month (220 class hours monthly plus 80 extra hours). Such cases raise questions

about the accuracy of the reported data and the underlying processes involved in calculating hours studied. This threshold can be considered quite conservative, and similar analyses could also consider lesser and more conservative thresholds.

Our investigation revealed significant findings across several states. State D reported the highest number of such enrollments in February 2024, with 2,891 enrollments exceeding the 300-hour threshold. Similarly, State E showed consistently high numbers, with 2,221 enrollments in February 2024 and 2,087 enrollments in March 2024. Other notable occurrences included State F, which reported 2,466 enrollments in November 2024, and State G, with 1,503 enrollments in February 2024. These patterns highlight potential systemic issues in the reporting of studied class hours. These inconsistencies suggest possible causes such as data entry errors, where hours studied were inaccurately recorded, miscommunication or discrepancies in how hours are calculated or aggregated at the institutional level, and the absence of validation mechanisms to flag and correct unfeasible data entries during the reporting process.

Design and Prototyping: To address these anomalies, we suggested implementing validation rules to flag cases where reported class hours exceed a predefined threshold. The prototype for these rules included automated checks to identify and mark entries exceeding the 300-hour limit for review. Historical data was used to simulate the behavior of these checks, allowing us to evaluate their effectiveness in identifying potential errors without hindering legitimate data. In addition to validation mechanisms, we designed a feedback loop involving institutional administrators. This process allowed flagged data to be reviewed collaboratively, ensuring that the identified anomalies were corrected or justified. Training materials and guidelines were developed to clarify how class hours should be calculated and reported, reducing the likelihood of recurring errors.

Implementation: The validation rules were integrated into the reporting system, ensuring entries exceeding the 300-hour threshold were flagged automatically for manual review. This integration occurred at both the data entry and aggregation stages, providing multiple validation layers to prevent unfeasible data from being finalized in reports. A retrospective cleanup was also conducted to address the anomalies identified in historical data. States with the highest occurrences of anomalies, such as State D and State E, were prioritized in this process. Communication channels were established with educational institutions in these states to resolve discrepancies and implement corrective measures.

Evaluation and Learning: The evaluation phase focuses on assessing the impact of the implemented measures. Metrics include a reduction in the number of enrollments reported with more than 300 class hours and improvements in the overall accuracy of reported class hours. Feedback from institutional administrators is suggested to be collected to refine the validation rules and ensure their practicality in day-to-day reporting. This case underscores the importance of robust validation mechanisms and collaborative review processes in maintaining data accuracy. By addressing the root causes of these anomalies, the system is better equipped to handle similar issues in the future, ensuring the reliability of data used for analysis and decision-making. Lessons learned from this case are being applied to other areas of data reporting to promote consistency and prevent the propagation of errors.

5.7. Case 7: Monthly Class Offered Hours Higher than 300

Problem Definition: An additional anomaly was identified in the data, involving cases where schools reported offering more than 300 class hours per month for enrollment. This threshold is considered unfeasible, as it implies an average of over 10 hours per day, which is highly unlikely under regular academic schedules. Such cases raise questions about the accuracy of the reported data and the processes involved in calculating the number of hours offered. Our analysis revealed several notable findings. State H reported the highest occurrence of such cases in February 2024, with 3,831 enrollments exceeding the 300-hour threshold. State I also exhibited consistently high numbers, including 2,221 enrollments in February 2024 and 2,087 enrollments in March 2024. Other states with significant occurrences included State J, which reported 1,503 enrollments in February 2024, and State K, with 2,898 enrollments in November 2024. These patterns suggest systemic issues that may lead to overreporting or inaccuracies in the reported hours offered. The anomalies could stem from data entry errors, such as inaccurately recording the number of hours offered, discrepancies in how hours are calculated or aggregated at the institutional level, or the absence of validation checks to flag and correct unfeasible data entries during reporting.

Design and Prototyping: To address these anomalies, we proposed developing validation rules to flag in-

stances where the reported hours offered exceed the 300-hour threshold. The validation process included automated checks to identify and mark records exceeding this limit for manual review. Prototyping used historical data to simulate these rules' behavior and ensure they effectively captured anomalies without hindering legitimate data entries. In addition to the validation rules, we suggested developing guidelines to standardize the reporting hours offered. These guidelines should emphasize the importance of accurate data entry and provide clear instructions on how hours should be calculated and aggregated. Training sessions were also suggested to educate institutional staff about these standards and the role of validation mechanisms in ensuring data integrity.

Implementation: The validation rules were integrated into the reporting system, with automated checks applied during data entry and aggregation. These checks flagged entries exceeding the 300-hour limit, ensuring they were reviewed, corrected, or justified. A retrospective cleanup process was also carried out to address historical anomalies, prioritizing states with the highest occurrences, such as State H and State I. Communication channels were suggested to be established with institutional administrators to facilitate the resolution of flagged inconsistencies and to ensure that corrective measures were effectively implemented. The reporting system was also enhanced to provide real-time feedback to users entering data, reducing the likelihood of future errors.

Evaluation and Learning: The effectiveness of the implemented solutions is being evaluated by monitoring the reduction in the number of enrollments exceeding the 300-hour threshold in subsequent reporting periods. Metrics such as the frequency of flagged anomalies, the resolution time for flagged cases, and feedback from institutional administrators are being used to assess the impact of these measures. This case highlights the importance of establishing robust validation mechanisms and fostering collaboration with institutional stakeholders to ensure accurate data reporting. The insights gained from addressing these anomalies are being used to refine the validation processes further and to apply similar approaches to other areas of data reporting. Through iterative learning, the system continues to evolve, ensuring the reliability and accuracy of reported data for analysis and decision-making.

6. Discussion

The seven cases of data inconsistencies previously presented can be broadly categorized into three main groups according to the types of errors found: Input Data Errors, Logical Inconsistencies, and Systemic or Aggregated Inconsistencies. Input Data Errors arise from manual data entry mistakes or the absence of proper validation mechanisms, as seen in cases like inconsistent enrollment dates and study hours exceeding offered hours. These errors rely primarily on validation and automated solutions to prevent mistakes at entry, together with training and educating users. Logical Inconsistencies occur when conflicting or unrealistic data is reported, such as students having multiple active enrollments or simultaneous active statuses with disenrollment justifications. Logical inconsistencies are mainly resolved through validation to enforce consistent logic and monitoring to detect real-time conflicts. Lastly, Systemic or Aggregated Anomalies reflect broader reporting or systemic issues, including implausible state-wide 100% attendance rates or unrealistic monthly study and offered hours that exceed feasible academic schedules. These errors require monitoring to flag irregular patterns and training to ensure adherence to reporting standards.

To foster data-driven public policies in education in Brazil, data infrastructure must be improved on the three fronts described by (Sellar, 2015), which are: *scales* across which the infrastructure is being integrated, the *scope* of the data being created, and the *explanatory power* enabled by the data infrastructure. SGP can be considered the first nationwide initiative focused on developing a unified database in the educational context that reaches the granularity of the data at a personal level (student level). In Brazil, public educational institutions are managed by different state entities according to their educational level. For instance, the Federal Government typically manages public federal universities, while State Governments manage high school education and, in some cases, Upper middle schools, and Municipalities manage Lower and Upper Middle schools and Early Childhood Education. Considering this administrative division, each public organization is also responsible for maintaining, securing, and managing its data (Filgueiras & Lui, 2023). This makes it very difficult to have an integrated student attendance centralized database, which is key for advancing evidence-based and data-driven policy capabilities in the country(Queiroga et al., 2024; Williamson, 2019).

Once that interoperability issues are overcome and data quality integrity is improved inside SGP, it becomes feasible to foster knowledge discovery inside the system to promote assertive public policies. For instance,

soon, it will become possible to evaluate student retention rates and compare the outcomes of beneficiaries and non-beneficiaries of social programs, enabling targeted interventions to address challenges in academic progression. Data integration also allows for analyzing school attendance patterns before and after specific events or seasons, such as natural disasters or agricultural cycles, helping policymakers design strategies to mitigate disruptions. Moreover, precise definitions for identifying dropouts, supported by accurate and comprehensive data, ensure precise tracking of students' educational trajectories and facilitate the development of effective measures to reduce dropout rates. Advanced techniques, such as explainable AI (xAI) and clustering, can help to provide a deeper understanding of attendance behaviors, highlighting high and low-risk groups for intervention. Integrated and high-quality data also support the development of tools to monitor the impact of educational programs, enabling continuous evaluation, refinement, and improved policy outcomes. At the regional level, data integration facilitates global and state-level clustering, allowing for the creation of tailored policies that address regional disparities and promote equity. Specific public educational program analyses become actionable through comprehensive datasets, offering insights into program effectiveness and identifying areas for improvement. Furthermore, SGP data may enable comparisons of economic indicators, such as resource allocation relative to population demographics, optimizing public investments in education, and enhancing outcomes across various contexts.

7. Final Remarks

The results from this study demonstrate the transformative impact of addressing data inconsistencies within Brazil's Sistema Gestão Presente (SGP). The application of a structured, data-driven methodology effectively helped to resolve critical challenges such as inconsistent enrollment dates, redundant active enrollments, and systemic reporting anomalies. Notably, introducing tailored validation mechanisms, automated error detection, and the proposal of enhanced training initiatives can significantly improve data integrity and usability. By systematically identifying and correcting anomalies, the SGP interactively enhances its reliability as a national educational database and establishes itself as a model for continuous quality assurance in large-scale public systems.

These findings provide valuable insights for other organizations aiming to improve the data quality of their systems. By adopting a similar approach that combines robust validation protocols, stakeholder engagement, and ongoing monitoring, other systems can achieve greater consistency and accuracy in their datasets. Additionally, the lessons from SGP's case studies highlight the importance of integrating technical solutions with user training and feedback loops. These practices help to ensure data quality and foster stakeholder confidence, enabling better-informed decisions and more effective public policies.

Abstract. In recent years, there has been growing scientific interest in developing effective techniques for forecasting student enrollment across the school spectrum (i.e., primary, secondary, and higher education). Enrollment forecasting is crucial in shaping public education policies by guiding resource allocation and ensuring equitable access to educational opportunities. In this sense, Machine Learning (ML) models emerge as a promising approach to forecasting the number of students that should be enrolled in a given school term by considering the high complexity of grouping and identifying useful patterns in the prediction process. In this work, we develop a predictive model based on the Random Forest (RF) algorithm to forecast the enrollment of students across the entire spectrum of Brazilian education. We use a database provided by the National Education Development Fund (FNDE), a Brazilian government body responsible for purchasing and distributing textbooks to all public schools. We generate 1,531,185 time series to serve as an input to RF processing. Our training dataset utilized data between 2010 and 2020, and our testing dataset utilizes data from 2021. As a result, RF obtains a higher performance in all the investigated scenarios concerning the Exponential Smoothing (ES) baseline algorithm. Since RF demonstrated acceptable performance, the Brazilian government could benefit from this forecasting technique for student enrollment in school environments and to ensure equitable access to essential resources, such as didactic materials, for the students.

1. Introduction

Brazilian education is extensive and consists of several levels and institutions. As an instance, this system encompasses Early Childhood, Basic, Secondary, Professional, and Higher Education. Some facts highlight the width of our education system: (i) Brazil has around 178.3 thousand basic education schools in operation, serving students in the initial years (1st to 5th), with a total of 105.4 thousand schools, and in the final years (6th to 9th), totaling 61.8 thousand schools; (ii) The municipal network is mainly responsible for offering the initial years, registering approximately 10.1 million students in 2022 (69.3%), equivalent to 85.5% of the public network; (iii) In the final years of primary education, the municipal network serves 5.3 million students (44.4%), while the state network serves 4.8 million (39.9%) (Andrade, 2023).

In this sense, millions of students are enrolled yearly in public or private schools to ensure access to quality education. Government bodies must have as an essential part of their public policies the ensurence of the availability of educational resources (e.g., textbooks and other didactic materials) for schools and students. In Brazil, the National Education Development Fund (FNDE) is responsible for delivering textbooks for these schools and ensuring that the content of these textbooks is used exclusively for educational purposes.

However, it is challenging to precisely forecast the number of students being enrolled each year. Currently, FNDE distributes textbooks according to projections from the school census for the two years prior to the program year, as this is the information available at the time of processing the choice made by the schools. Such forecasts are carried out using the Exponential Smoothing method (Billah et al., 2006). Therefore, there may be small fluctuations between the number of books and the number of students. The greater this fluctuation, the greater the financial cost in the process, due to the excess of books that will be purchased and distributed. Furthermore, the lack of a precise number implies that many students do not receive textbooks during the school period, causing great harm to their education and hindering fair and equal educational development.

In recent literature, the context of the problem of predicting job enrollments is mainly in university environments (Ayasi et al., 2023; Khademi and Nakhkob, 2016; Shao et al., 2022) and has a significant number of related studies. In the school context, there is a minimal number of studies (e.g., Abideen et al., 2023) and the scope of the experiments is not representative, due to the small sample size. Our work has a much more comprehensive and representative scope, in addition to being applied to a complex and challenging scenario.

As highlighted (Scholl, 2024), the Digital Government Research (DGR) field has evolved significantly in recent years, especially in developing solutions for public administration. These solutions aim to bring government closer to society through technologies, such as the services offered to the population, social media as a means of communication, and Artificial Intelligence as a tool to support decision-making. In this sense, this paper investigates using Machibe Learning (ML) models to forecast the number of enrolled students (Sarker, 2021). We develop a predictive model based on the Random Forest (RF) algorithm (Pichler and Hartig, 2023) able to forecast the enrollment of students across the entire spectrum of Brazilian education.

The research methodology adopted for this work is based on the Design Science Research (DSR) paradigm (Gregor and Hevner, 2013; Hevner et al., 2004). To apply the DSR methodology, we followed the guidelines of (Peffers et al., 2007), which specify the process in a sequence of six activities: 1. Identify the problem and motivation; 2. Define the objectives for the solution; 3. Design and develop; 4. Demonstrate; 5. Evaluate; 6. Communicate. Figure 1 presents the DSR methodology process defined for this work.

Therefore, considering the complexity (Sobrinho et al., 2023) and the high cost (FNDE, 2022) of the Brazilian government to the processes involving the acquisition and distribution of books to students in public schools (Activity 1), our motivation is to improve decision-making by FNDE, proposing predictive models based on machine learning to more assertively and automatically infer the number of students at each stage of education in each school (Activity 2), minimizing the financial losses of the government (e.g., excessive purchases) and social losses (e.g., students without access to teaching materials).

We used a database provided by the FNDE to develop the proposed predictive model (Activity 3). We generate 1,531,185 times series to serve as an input to the RF processing. We also use a data mining process with an interpolate imputation method that mitigates null values in the dataset and a hold-out method that splits the dataset into training and testing sets. Our training dataset utilizes data proceeding from 2010 to 2020.

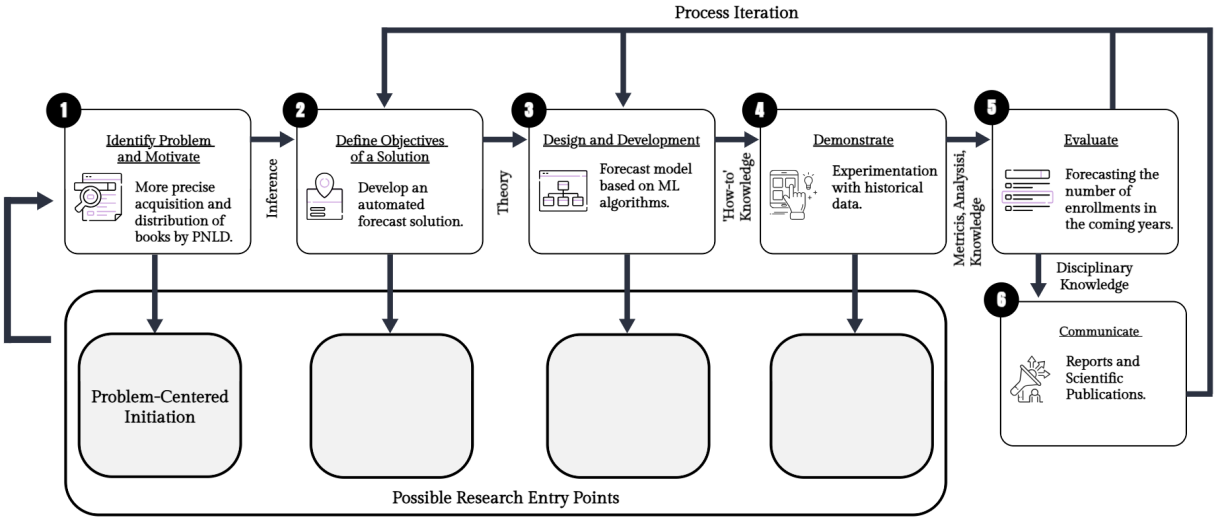

Fig. 1 – DSR Process. Adapted from Peffers et al., 2007.

For demonstration purposes (Activity 4), we used historical data from 2021 as our testing dataset and considered in the experiments the aspects of school grade, geographic location, Brazilian regions, federative unit, population size, dependence type, and school size. As a result, RF obtains higher performance in all the investigated scenarios in relation to the Exponential Smoothing (ES) baseline algorithm. The ES algorithm was chosen as a comparative baseline with the RF because in the related literature (Chen, 2022) it achieved better accuracy and stability in forecasting the number of high school enrollments and vocational education enrollment.

Since the RF demonstrated acceptable performance in forecasting student enrollments in school environments, the next step is to integrate the model into the system used by FNDE to forecast the enrollments in the coming years (Activity 5). Finally, for communication purposes (Activity 6), we wrote technical reports about the entire research and development process of the proposed predictive model and provided them to FNDE. Additionally, we carry out the process of scientific writing and publishing articles based on the results achieved with the experiments performed.

The main contributions of this study are two-fold:

1. the proposition of an ML model for automatic prediction of enrollment in public schools in Brazil aims to increase efficiency and reduce the time needed to perform this challenging task of forecasting the number of student enrollments in each class of each public school in a country of continental geographic dimension;
2. the provision of a solution to support FNDE's decision-making in effective planning for the distribution of textbooks in the country, with the possibility of reducing financial costs and social impacts on Education.

The justification for using ML algorithms as an alternative solution to the Exponential Smoothing method used by FNDE to forecast student enrollment is based on the ability of such algorithms to make predictions without the need for explicit programming, learning automatically from historical data (Sarker, 2021). This flexible and dynamic nature of learning makes ML algorithms the ideal solution for complex prediction problems, such as predicting student enrollment.

Studies such as those by (Fischer-Abaigar et al., 2024) and (Amarasinghe et al., 2023) emphasize the alignment of ML models with real-world complexities, ensuring that their outputs are actionable, explainable, and equitable. These works argue for a shift from purely predictive goals to decision-making frameworks that prioritize policy impact.

The work structure is presented as follows. Section 2 highlights some literature works that investigate the usage of ML techniques for enrollment forecasting-related issues. Section 3 describes the RF model that it

utilized as a baseline for running our experiments. Section 4 presents scenarios and methodology utilized in our experiments. Section 5 presents the results extracted from our experiments and discussion. In Section 6 we present our concluding remarks.

2. Related Work

Machine Learning (ML) is a subset of Artificial Intelligence (AI) that focuses on the development of algorithms and models that enable computers to learn and make predictions or decisions without being explicitly programmed, hence the term learning (Sarker, 2021). ML deals with the design and construction of systems that can automatically learn and improve from experience, typically by analyzing and extracting patterns from large amounts of data. The RF algorithm belongs to the ensemble learning category of ML algorithms using bagging and boosting techniques (Pichler and Hartig, 2023). They are renowned for their robustness and versatility in both classification and regression tasks. Within the ensemble framework, RF operates by constructing multiple decision trees during training and then aggregating their predictions to make a final prediction. With their ability to deliver accurate predictions and interpretability, RF has become a popular choice for various predictive modeling tasks across different domains, including Education (Sarker, 2021).

The task of accurately forecasting school enrollment rates is critical for school management. It allows to minimize unnecessary administrative costs as well as burdens to both students and faculty. In addition, it is possible to adequately plan for the number of classes, teachers, and resources needed to meet students' demands. The use of ML models to forecast student enrollment in schools has shown to be a promising approach to dealing with this problem, as observed in the literature (Abideen et al., 2023; Masini et al., 2023; Shao et al., 2022).

Several related works have emerged in the literature in recent years. (Feng et al., 2011) analyzed enrollment data from 25 randomly selected Chinese provinces as training data to predict enrollment rates in another six provinces using an Artificial Neural Network (ANN) model combined with association rules. The authors stated that the proposed model is viable and effective in supporting decision-making in university admissions.

(Khademi and Nakhkob, 2016) used classical ML models (Logistic Regression - LR, Naive Bayes - NB and Decision Tree - DT) and Artificial Neural Networks - ANN (MultiLayer Perceptron - MLPs) combined (*bagging* and *boosting*) to predict the increase in enrollment in universities in Iran. The results showed that the model was able to accurately predict the increase in enrollments based on historical data, student demographic information, and socioeconomic data from the region, reaching almost 96% accuracy with the best model.

A study designed by (Soltys et al., 2021) used an AI services framework from Amazon Web Services (AWS), SageMaker, along with standard Python tools for data analysis, including Pandas, NumPy, Matplotlib, and Scikit-Learn [1]. Based on three years of enrollment history, a model was built to calculate, individually or in batch mode, enrollment probabilities for certain candidates. The idea was to use these probabilities during admissions periods to target undecided students.

More recent research by (Ayasi et al., 2023) delves into the application of ML and neural network algorithms in forecasting future student enrollments in higher education courses. Utilizing real data from the Arab American University in Palestine (AAUP), the study employed eight ML algorithms alongside the Multilayer Perceptron (MLP) neural network model to anticipate the enrollment likelihood of students in specific courses. Findings indicate that ensemble-based and bagging algorithms outshine other classifiers, including neural network models, in forecasting individual-level student enrollments. Notably, the RF achieves a remarkable accuracy of 94% and an F1 score of 79% following the application of undersampling techniques to address dataset imbalance. The study suggests future research endeavors to develop a universal model for forecasting enrollment across all courses at AAUP, underscoring the efficacy of these techniques in enhancing resource allocation and student support.

(Shao et al., 2022) developed a study to replicate course enrollment forecasts through a conditional probability analysis utilizing student data from San Diego State University. Subsequently, the study sought to enhance these predictions by employing classification and regression trees (CART) and the RF algorithm. By integrating student demographic and academic information into the algorithms, the authors aimed to evaluate their

[1] https://scikit-learn.org/

impact on refining the accuracy of course enrollment predictions. Furthermore, the authors conducted an analysis to determine the most influential factors affecting General Chemistry enrollment numbers, utilizing a variable importance metric derived from tree-based algorithms.

Finally, (Abideen et al., 2023) analyzed five years of enrollment data from 100 schools within Punjab, Pakistan. Essential features have been extracted and analyzed using various ML algorithms, including Multiple Linear Regression, RF, and Decision Tree. These algorithms play a crucial role in forecasting future school enrollments and classifying target levels for each school. The findings enable a brief analysis of forthcoming registrations and target levels. Moreover, the proposed model aids in identifying solutions to address low enrollment rates in schools, thereby contributing to the enhancement of literacy rates within the region.

Therefore, the main differences between our work and the aforementioned related works are the following: 1. our scope is broader and is related to public schools in Brazil and their respective educational stages, while the cited literature has a more specific scope with a primary focus on universities around the world (e.g., USA, China, Iran, and Palestine); 2. our work involves a complex, challenging and socially impactful context, while the contexts of the aforementioned works do not present these characteristics; 3. we propose a solution using Random Forest, a traditional Machine Learning algorithm, simple to implement and that does not require as many computational resources to execute, while most of the solutions identified in the literature, despite making use of modern and robust algorithms, such as Artificial Neural Networks, require a better computational infrastructure.

3. Forecasting Student Enrollments

This section presents the methodological step-by-step for conceiving the predictive model based on Random Forest algorithm as a potential solution for projecting enrollment in classes in elementary education schools in Brazil.

3.1. Dataset

In this work, we designed a predictive model using a dataset provided by FNDE. The dataset comprised 10,980,537 enrollment records of Brazilian Basic Education schools. To filter the dataset, we used the year and school grade code criteria, which resulted in 33 teaching stages and 12 years of school census data, spanning from 2010 to 2021. In addition, the dataset contains a total of 221.771 schools distributed in 5.570 Brazilian cities. The school records has six variables, as illustrated in Table 1: (a) Census Collection Year (YEAR); (b) Municipal Code (MUN_CO); (c) School Code (CD_SCH); (d) School Grade Code (GRADE_CD); and (e) Number of Students (STD_N).

Tab. 1 – A random sample with five records from the investigated dataset.

YEAR	MUN_CO	CD_SCH	GRADE_CD	STD_N
2010	43016413	4301107	15	1
2013	21097690	2105500	19	78
2012	23165820	2307304	20	11
2014	22134484	2210938	21	16
2019	21001219	2101301	16	2

In the predictive analysis proposed in this study, we only used the variables YEAR and STD_N. The other variables were used only to compare the performance results of the models according to the scenarios defined for the experiments.

Table 2 presents the descriptive statistics of the main variables present in the dataset, providing an idea of the data profile.

As seen in Table 2, the variable STD_N (target) presents an average of 49.29 students enrolled, with a median of 26 and standard deviation of 75.36. The minimum number of registered enrollments is equal to 1, while the maximum number is 31,542. These numbers characterize a discrepant variation in enrollments among Brazilian schools.

Tab. 2 – Descriptive Statistics of the dataset provided by the FNDE.

Variable	Mean	Median	Std. Dev.	Min.	Max.
YEAR	-	-	-	2010	2021
STD_N	49.29	26	75.36	1	31,542

3.2. Model

The biggest challenge in time series forecasting with traditional ML methods is setting up the problem correctly. There are basically three different possibilities by which we can classify a time series forecasting problem as a Supervised ML problem, namely:

1. Predict the next time step using previous observations;
2. Predict the next time interval using a sequence of past observations;
3. Predict a sequence of future time steps using a sequence of past observations.

In this work, we will frame the problem as non-prediction of school enrollment for the coming year using historical data from previous years. In this configuration, the model will generate a prediction for the next time step, considering only the previous observation.

For our analysis, it was necessary to organize the dataset in such a way that previous observations (historical time series) become a resource to predict the next observation (forecasting of enrollments in subsequent years). Therefore, we added a second column (y) that shifts the STD_N column so that the value in one year (red line, e.g., 2019) becomes a predictor of the value for the next year (blue line, e.g., 2020), allowing the comparison shown in Figure 2.

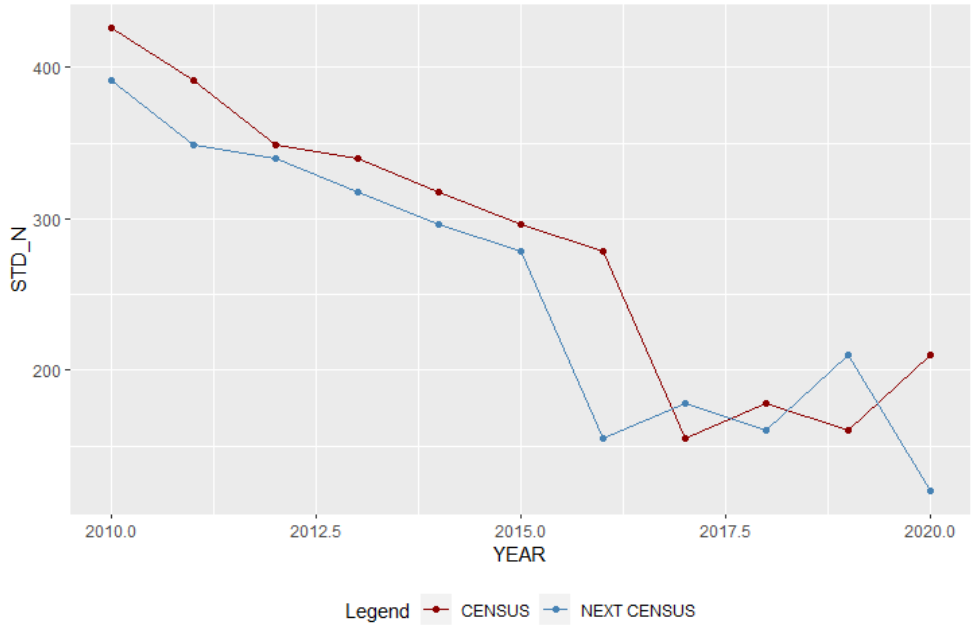

Fig. 2 – Example of viewing the series 15042537.

After arranging the data for the analysis proposed in the work, we started the experiments, as described in Section 4.

4. Experiment

In this work, we develop an experiment to validate the efficiency of RF into scenarios of forecasting Student Enrollments. The following metrics are utilized to measure this efficiency: (i) R^2 (R-squared) (Hiregoudar,

2020); (ii) MAE (Mean Absolute Error) (Penteado, 2021); (iii) MAPE (Mean Absolute Percentual Error) (Penteado, 2021); (iv) MASE (Mean Absolute Scaled Error) (Hyndman and Koehler, 2006); (v) MSE (Mean Squared Error) (Penteado, 2021); (vi) RMSE (Root Mean Squared Error) (Penteado, 2021); (vii) RAE (Relative Absolute Error) (Hiregoudar, 2020); and (viii) U-Theil (Bliemel, 1973).

4.1. Scenarios

The scenario utilized in this work is described as follows. We adopt Brazilian primary schools as our baseline scenario to perform forecasting techniques. In that sense, we investigate the dataset with the following concerns:

- **Global:** it encompasses the application of metrics along all the considered dataset with no filtering utilization. In this case, we consider previously considered filters, being deleted null data.
- **Teaching Stage:** it encompasses grouped data in according with the teaching stage, thus being defined by 36 categories;
- **Geographic Location:** it encompasses grouped data in according with the location in the urban perimeter of schools, thus being defined by Urban and Rural categories;
- **Brazilian Regions:** it encompasses grouped data in according with the location of schools in Brazilian Regions, thus being defined by the categories: (a) North; (b) Northeast; (c) East Center; (d) Southeast; and (e) South;
- **Federative Unit:** it encompasses grouped data according to the location of 27 Brazilian states;
- **Population Size:** it encompasses grouped data according to the population ranges of cities and municipals that encompass such schools, thus being defined by the following categories: (i) Up to 20 thousand inhabitants; (ii) Between 20 and 50 thousand inhabitants; (iii) Between 50 and 100 thousand inhabitants; (iv) Between 100 and 500 thousand inhabitants; (v) Between 500 and 1 million inhabitants; and (vi) Over 1 million inhabitants;
- **Dependency Type:** it encompasses grouped data by school sector, and its categorization is: (1) Federal, (2) State, (3) Municipal, (4) Private, and (5) All Public.
- **School Size:** categorized into five classes (1 to 5), the first being the smallest (smallest range of total number of students per school) and the last being the largest, the entities/schools according to their statistical distribution in the population (quantiles) for each year analyzed.

To carry out our experiments, we grouped the data according to each scenario mentioned above. In this way, we were able to discuss the performance results of RF and ES algorithms (baseline) according to the context analyzed in each experiment.

4.2. Design Methodology

Figure 3 presents the steps of the design methodology defined for the model development and evaluation.

Starting from a dataset provided by FNDE, we generate 1.531.185 times series in order to serve as an input to RF processing. The composition of these series is performed by grouping the following columns: (a) *CD_SCH*; (b) *MUN_CO*; and (iii) *GRADE_CD*. Likewise, we estimate the regression value for the reference year 2021.

We utilize the *interpolate* imputation method (Robinson and Hamann, 2011) to mitigate absent values in the investigated dataset since it presents acceptable performance to reduce dataset-related prediction errors. Moreover, we also use the *hold-out* method (Sammut and Webb, 2017) to slice the dataset into two subsets: a training one, used to tune the model, and a testing one, used to evaluate the model's performance in forecasting the data not belonging to the training subset. We have partitioned the training dataset with data proceeding from 2010 to 2020 to each entity, and we define the testing dataset with data proceeding from 2021.

Each school and teaching stage is represented by the regression estimated value. Therefore, such value is obtained for each time series and concatenated, thus generating a new dataset. Therefore, the model was evaluated by processing error measurement metrics and model evaluation. We utilize a *random state* in the enrollment forecasting model using the RF in order to ensure scientific-level repeatability. Although the RF model was designed based on the pre-processed dataset, the prediction results were filtered by each scenario to allow for a more in-depth discussion.

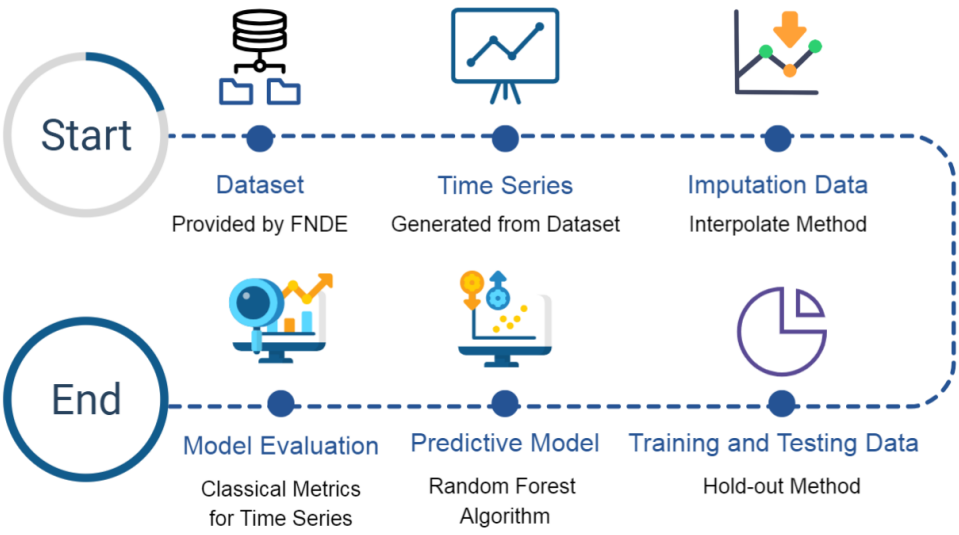

Fig. 3 – Development and Evaluation Process.

Finally, the computing environment used to perform the experiments consists of a computer with an Intel(R) Xeon(R) E-2244G processor, with CPU cores of 3.80GHz, and 32.0 GB of RAM memory. We understand this information is relevant since processing time is an important factor in the practical application.

5. Results

This section presents the results and discussion on predicting enrollment in Brazilian schools using the Random Forest (RF) algorithm and comparing its performance with the baseline model that uses the Exponential Smoothing (ES) technique.

Table 3 presents the *benchmarking* results of the designed model by contrasting the RF algorithm with the ES model in the "Global" scenario with complete dataset. In this scenario, except for U-Theil, we observed a better performance of the RF in all other metrics evaluated.

Tab. 3 – Evaluation of RF *vs.* ES (baseline) models for the "Global" scenario.

Model	R^2	MAE	MAPE	MSE	RMSE	MASE	RAE	U-Theil
ES	0.83	12.52	46.97	941.63	30.69	0.44	0.29	**0.25**
RF	**0.87**	**11.62**	**42.01**	**745.04**	**27.30**	**0.41**	**0.27**	0.26

In other investigated scenarios, we first have calculated the values of each metric in each subcategory and then we have calculated the average. For example, in the "Teaching Stage" scenario, the comparative results between the ES (baseline) model and the RF algorithm are presented in Table 4. As a result, the performance of the models in this scenario is similar to that of the "Global" scenario, but with a reduction in R^2 and an increase in the values of the error metrics, with the exception of MASE.

Tab. 4 – Evaluation of RF *vs.* ES (baseline) models for the "Teaching Stage" scenario.

Model	R^2	MAE	MAPE	MSE	RMSE	MASE	RAE	U-Theil
ES	0.76	21.70	57.45	2952.4	41.49	0.35	0.41	**0.507**
σ ($\pm$)	0.20	14.00	45.70	5975.0	35.60	0.14	0.18	0.230
RF	**0.79**	**20.20**	**52.80**	**2537.18**	**38.43**	**0.332**	**0.38**	0.514
σ ($\pm$)	0.18	12.70	36.20	5313.00	33.10	0.130	0.17	0.230

We applied the paired-samples t-test (Xu et al., 2017), where the null hypothesis (H_0) assumes that the true mean difference (μd) is equal to zero. Table 5 shows the *p-values* calculated for each metric used to evaluate

the model's performance. Considering the statistical significance of $p \leq 0.05$, when analyzing the *p-values* of all metrics, we found that they are lower than 0.05. Therefore, we confirm the hypothesis that there is a statistical difference between the performance results of the RF and ES models.

Tab. 5 – T-test - Paired Two Sample for Means: "Teaching Stage" scenario.

Metric	***p-value***
R^2	0.0005579
MAE	9.865728e-06
MAPE	0.02979593
MSE	0.02354106
RMSE	0.0009053389
MASE	1.362274e-06

In relation to "Geographic Location", the results presented in Table 6 demonstrate a superiority of RF, with emphasis on the R^2 metric.

Tab. 6 – Evaluation of RF *vs.* ES (baseline) models for the "Geographic Location" scenario.

We conducted a paired t-test to compare the means of each metric of each model across different scenarios, similar to what we did for the "Teaching Stages" scenario. The results for the "Geographic Location" scenario are presented in Table 7. The obtained *p-values* for the metrics R^2, MAPE, MASE, and RAE were below 0.05, indicating a statistical difference between the means of these metrics for the ES model compared to the RF model. However, there was no statistical difference observed for the MAE, MSE, RMSE, and U-Theil metrics, suggesting similar performance of both models for these metrics.

U-Theil	0.1019322

In the "Brazilian Regions" scenario (see Table 8), the RF has achieved a better performance than the ES model (*baseline*). This behavior is repeated in scenarios that encompass data grouped by "Federation Unit", "Population Size" and "Type of Dependency", as shown in Tables 10, 12, 14, and 16, respectively.

We show the results of the paired t-test for the "Brazilian Regions" scenario in Table 9. The *p-values* calculated for all metrics allow us to reject the null hypothesis and conclude that the means are statistically different when comparing the performance of the ES and RF models. A similar result is also observed in the "Federative Unit" scenario, as shown in Table 11.

The results of the paired t-test for the "Population Size", "Dependency Type", and "School Size" scenarios are shown, respectively, in Tables 13, 15, 17. In these scenarios, there were many variations in results. For example, in the "Population Size" scenario (see Table 13), except the *p-value* obtained for the R^2 metric, the other

σ ($\pm$)	0.025	8.54	17.6	1841	21.60	0.052	0.05	0.270

are statistically different.

Tab. 15 – T-test Paired Two Sample for Means: "Dependency Type" scenario.

Metric	***p-value***
R^2	0.02513679
MAE	0.03603456
MAPE	0.0005633837
MSE	0.1921146
RMSE	0.0353659
MASE	0.09901843
RAE	0.09540237
U-Theil	0.6418034

Tab. 16 – Evaluation of RF *vs.* ES (baseline) models for the "School Size" scenario.

Model	R^2	**MAE**	**MAPE**	**MSE**	**RMSE**	**MASE**	**RAE**	**U-Theil**
ES	0.659	12.53	46.9	943	24.9	0.493	0.46	0.507
σ ($\pm$)	0.204	9.60	14.1	1393	20.2	0.063	0.09	0.203
RF	**0.70**	**11.64**	**41.9**	**746**	**22.3**	**0.461**	**0.43**	**0.453**
σ ($\pm$)	0.21	8.88	14.1	1079	17.6	0.066	0.09	0.247

Finally, for the "School Size" scenario (see Table 17), in addition to the *p-value* of R^2, the *p-values* for the MAPE, MASE and RAE metrics were less than 0.05, allowing us to conclude that the means are statistically different for the ES and RF models. Differently, the averages for the MAE, MSE, RMSE, and U-Theil metrics are statistically similar, as the *p-values* were greater than 0.05.

Our experiments have presented relevant results, thus enabling the comparison of the ES (*baseline*) model in time series with the performance of the RF algorithm. Given the experiment results, we understand that there is a variation in performance of the RF-based model in accordance with the scenario. For example, in the "Teaching Stages" and "School Size" scenarios, both models performed less than 0.8 for the R^2 metric. In the scenarios "Geographic Location", "Federative Unit", "Population Size" and "Dependency Type", only the RF model performed better than 0.8 for the R^2 metric. Only in the Global and "Brazilian Regions" scenarios did both models exceed the value of 0.8 for the R^2 metric.

When it comes to the error metrics MAE, MAPE, MSE, RMSE, MASE, and RAE, the RF model reduced the value of

Tab. 17 – T-test Paired Two Sample for Means: "School Size" scenario.

Metric	***p-value***
R^2	8.62111e-05
MAE	0.05070706
MAPE	5.064793e-05
MSE	0.234543
RMSE	0.09082856
MASE	0.0004177525
RAE	0.0004358726
U-Theil	0.3324351

the prediction error in all scenarios: "Global", "Teaching Stages", "Geographical Location", "Brazilian Regions", "Federative Units", "Population Size", and "Type of Dependency".

For the U-theil metric, specific to evaluating predictive models for time series, the baseline model outperformed RF only in the "Dependency Type" and "School Size" scenarios.

Considering all the variations of the analyzed scenarios, we obtained 86 results in total. Analyzing the frequency of the best performing models (ES *vs.* RF), the supremacy of the RF algorithm was evident in all scenarios, with a processing time of 160934.6 seconds.

As mentioned in Section 2, this work focuses on public schools in Brazil. However, our solution can be adopted in other countries with different realities. While it is most suitable for countries similar to Brazil—particularly developing nations with heterogeneous income distribution and economies influenced by major world powers—our approach can also benefit underdeveloped countries, especially those in the Global South. These countries, despite having low socioeconomic indicators and the Health and Education sectors are mostly the government's responsibility, can utilize our solution due to its simplicity and minimal reliance on computational resources.

6. Concluding Remarks

The Brazilian National Textbook Program (Programa Nacional do Livro e do Material Didático — PNLD) is one of the largest and most democratic government programs for education in Brazil. It was created in 1938, but was entitled of PNLD in 1985, to distribute textbooks, pedagogical and literary books, and other educational materials to teachers and students in public schools throughout the country (Sobrinho et al., 2023). Given the vast geographic, economic, and cultural diversity of the country, it is not easy to estimate the exact number of students in each class at each school in every Brazilian municipality.

This paper highlights the untapped potential of machine learning in transforming enrollment forecasting into a powerful tool for public policy. The study investigated a RF-based ML Model to forecast student enrollment in Brazilian schools. We used as a scenario the public school, and we created a dataset to carry out this forecasting. RF with ES as baseline to verify the performance of enrollment forecasts in public schools. The results show an improvement in the distribution process, allowing children to have access to books and improving equity. As a consequence, implementing a solution that is less likely to have prediction errors can significantly reduce the issue of having too many books in schools, which leads to financial waste. Additionally, this solution can also solve the problem of students not receiving books due to their unavailability, which results in inestimable losses in terms of their education.

This type of experiment seeks to provide more effective solutions compared to the ES model used by the Brazil-

ian government, as it is not just about forecasting the number of enrollments in classes in basic education schools in Brazil. The use of this information becomes even more important for government bodies responsible for Brazilian Education to plan the acquisition of teaching resources, such as books, to meet the demands of society.

In this context, having an effective solution for predicting the number of students who will enroll in each class in each school the following year allows the government to make more efficient decisions regarding purchasing books and other didactic materials to be distributed in schools. Thus, regarding the state of the practice, we characterize the advancement of our work by proposing a predictive model based on a machine learning algorithm that does not require assumptions (i.e., Random Forest), unlike the Exponential Smoothing method, which requires data to be stationary and predictions to be short-term. Therefore, our solution assists the Brazilian government in optimizing resources for education, ensuring equal access to didactic materials for all students in public schools.

As limitations, we identified the following points: (i) During the descriptive and graphical analysis stage of the data present in the dataset, we observed that there were observations with values that deviated from the standards of the large mass of data. However, we decided not to analyze in this study the influence and impact of these data on the performance of the models, baseline, and RF, therefore characterizing a limitation of this study. (ii) We only use historical data relating to the number of enrollments in previous years as predictors to forecast the number of enrollments in the following year. This decision limited the solution to a reduced set of variables that, perhaps alone, were insufficient to explain the value of the target variable.

In order to work on the limitations, we suggested the following future works: (i) investigate the characteristic observations of outliers and influential points in the dataset that may impact the performance of the models; (ii) enhance the performance of our proposed predictive model, adding more predictor variables. For this purpose, we can use the microdata from the Brazilian basic education census provided by INEP. This dataset contains over 300 attributes, which should provide us with ample options to choose other variables. Once we have added these variables, we need to evaluate the impact of this change on the model's performance; (iii) optimize the model parameters through *tunning* techniques such as *GridSearch* or *RandomSearch*, which have the potential to improve prediction and evaluation results of predictive models; (iv) In addition, other ML models will be tested, aiming to present a fairer comparative analysis and seek even better solutions to the enrollment forecast problem; (v) Finally, we will present the results of this work to the FNDE and propose integrating our solution into the enrollment prediction system used by the Brazilian government.

Abstract. Data-driven decision-making has become more prevalent in the field of digital government. Data visualization as a key tool for data exploration, can help decision makers quickly understand data and grasp insights behind pages of spreadsheets. To better support scientific discovery through advanced research computing, the U.S. National Science Foundation has funded the cyberinfrastructure programs including TeraGrid, XSEDE, and ACCESS for over twenty years. These programs have generated extensive data about the awarded projects along with their resource allocation and usage. However, existing visualization tools for these data were not designed for in-depth analysis or direct decision-making support. This research investigated the needs of resource providers and users, analyzed the data collected from TeraGrid and XSEDE projects between 2003 and 2022, and developed a publicly accessible interactive visualization dashboard. The goal of this visual platform is to enable resource providers and users to independently explore data through graphs and tables and make informed comparisons and decisions. Resource providers can use the platform to study and compare trends in resource allocation and usage across projects funded at various institutions and within different fields, identify more efficient resource users and research directions, and provide personalized services to institutions and principal investigators in need. Resource users can search for potential collaborators and helpers from successful cyberinfrastructure project awardees in similar fields, nearby locations, or related research topics. Additionally, this paper demonstrates the practical application of the visualization dashboard through three examples: a research-intensive institution, an under-represented minority-serving institution, and a junior researcher from a specific field of science, showcasing how each can leverage the platform for decision-making.

1. Introduction

In the era of data explosion, making full use of data science can significantly improve comprehensiveness, rationality, timeliness and effectiveness of decision-making. Big data can be employed to depict the comprehensive characteristics of static events and the development trends of dynamic events. This enables decision-makers to

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

more easily identify challenges or issues, determine the most appropriate actions or intervention timings, simulate the potential outcomes and impacts of decisions, and ultimately select the optimal decision under given constraints. However, data science also presents unique challenges, such as how to collect, organize, and store massive amounts of data, how to extract valuable insights from massive data, and how to effectively communicate the summarized data value to policy makers and beneficiaries. Within the chain from data to decision, data visualization serves as a critical link to help stakeholders understand data.

Data visualization uses graphical displays to show data and information (Unwin, 2020). For most people, interpreting information from visual graphs is more direct and efficient than browsing raw data or reading summary tables, without losing accuracy. Data visualization can assist in the decision-making process by presenting important information such as numerical distributions, categorical comparisons, temporal progress, and spatial trends. Statistical graphics can also show comparisons of data distributions under multiple different conditions by selecting correct graphical elements such as graph types, colors, shapes, sizes, and page layouts, etc. Therefore, data visualization can play an essential role in summarizing information and comparing options during decision-making.

In digital government, data-driven decision-making has become more extensive and in-depth (van Ooijen et al., 2019) and the potential of leveraging artificial intelligence (Charles et al., 2022). For instance, statistical data collected by federal, state, and local governments are often publicly available on the government websites like data.gov in the United States. The public can view and understand transparent, data-based government decisions. Meanwhile, individuals may use open data for personal decision-making or to influence government decisions from the bottom up. On government websites, visualization is increasingly being used in the form of data dashboards to provide more convenience to the public.

While significant progress has been made with the growth of data-driven decision-making in digital government, there remain opportunities for further enhancement in some areas like social services (Ryan et al. 2014; van Ooijen et al. 2019; Charles et al. 2022). Although large datasets have been collected in these areas and basic descriptive statistics are often reported, there is a potential to uncover deeper, more valuable insights from the data, such as causal inference, predictive modeling, and equity-focused evaluation. To smooth the decision-making process with data visualization, this study will take the high performance computing services of advanced scientific research projects funded by the U.S. government as a digital government project to showcase the design concept and product examples of interactive visualization platforms; also, to show how the visual products could help both policymakers and potential beneficiaries to explore the value of data and strengthen their analytical and decision-making capabilities.

High performance computing (HPC) is a technology that uses supercomputers or processor clusters to parallelly process massive data and complex calculations at a high speed. HPC is of great significance in accelerating scientific discovery and enhancing technological invention. To provide powerful HPC services for U.S. scientific researchers, the National Science Foundation (NSF) has invested $270 million on the cyberinfrastructure (CI) programs (Chen & Knepper, 2021), including the TeraGrid (Reed & Berman, 2001), the Extreme Science and Engineering Discovery Environment (XSEDE) 1.0 and 2.0 (Towns, et al., 2011; XSEDE, 2016), and the more recent Advanced Cyberinfrastructure Coordination Ecosystem: Services & Support (ACCESS) (Boerner, et al., 2023). And NSF's investment has been well paid off. According to Stewart, et al. (2022), the XSEDE program provided a return of more than $1.5 in value for every $1.0 invested by the U.S. Government during 2014 to 2020.

To further develop the HPC CI programs, both the program operation team and users may be interested in addressing questions such as: How to allocate computing resources more efficiently? How to better support inexperienced users to start their HPC projects conveniently? How to advertise the CI programs and encourage more researchers to apply for and utilize these resources and services? How to broaden participation of under-represented individuals and groups? While domain experts may have answers to these questions based on years of experience, insights can also be gained from a data perspective. By analyzing data collected from the TeraGrid/XSEDE projects across almost 20 years, decision makers and scientific users can reveal user behaviors hidden behind the allocation and usage data, offering valuable answers to these critical questions.

The main contribution of this work is to produce an interactive data visualization platform for government-funded HPC cyberinfrastructure services via the user-centered co-design. This platform will provide decision-making support for two groups. For computing service providers, the platform displays and compares the resource allocation and utilization efficiency of research projects using the XSEDE services over the years, aggregated at the institution, field of science, and individual investigator levels, which would assist in finding ways to optimize CI operations. For novice and potential users of HPC services, the visualization platform can help them find potential research collaborators and topics, build the foundation, and boost the confidence to start their HPC projects.

The second section reviews the literature on data visualization and the application of big data in digital government. The third section examines two data visualization tools of the NSF CI programs and introduces the

design concept and framework structure of the interactive graphics platform. The fourth section provides a detailed overview of the TeraGrid/XSEDE data and the interactive dashboard, including examples that demonstrate how to utilize the platform. The final section presents a summary of findings and discusses future work.

2. Data Visualization and Decision-making

Data visualization is an important part of Exploratory Data Analysis (EDA). After collecting data, visualizations can be used to examine distributions, outliers, and missing values. This helps assess the discreteness and correlations among variables, handle outliers and missing data, and check the assumptions of statistical models. Moreover, visualizations can uncover key insights or "highlight stories" within the data and effectively communicate statistical results after the analysis is completed.

2.1 Data visualization: types, development, and applications

According to the development stage of data visualization, we divide graphics into static graphics, dynamic graphics, and interactive graphics.

Static graphics are fixed visual displays that do not move or change. They have been used to provide important decision-making information for hundreds of years. For example, in mid-1800s, Florence Nightingale created the polar time series plot to show death rates and causes of British soldiers in the Crimean war (Cohen, 1984). At about the same time, John Snow mapped cholera deaths in London, identifying a water pump as the outbreak's source (Snow, 1856). Modern static graphics usually choose the type of plot based on the types of variables. Univariate distributions can be visualized with histograms or density plots for continuous variables and bar charts for categorical ones; line plots reveal trends in time-series data. For bivariate cases, scatterplots show correlations between continuous variables, mosaic plots display associations between categorical variables, and boxplots or violin plots compare continuous variables across categories. Multivariate relationships can be explored with pairwise plots using univariate visuals on the diagonal and bivariate visuals off-diagonal, or with parallel coordinates plots, where each variable is shown on a vertical axis and observations are connected by lines, revealing patterns such as correlations through line alignment or crossing.

In terms of graphing methods, Cleveland (1984, 1985) discussed the theory of visual perception and the principal elements of graphics. Wilkinson (2005) denoted the grammar of graphics (GoG) system with seven orthogonal class methods to transform data from a raw dataset to a statistical graphic. Wickham (2010) implemented the GoG principles into the R language and developed the well-known graphics package ggplot2. In other software, the design and development of modern graphics packages are also influenced to some extent by GoG and ggplot2 (Morel, 2018; Yim, et al., 2018).

As data volumes grow and software technologies develop, there is a demand for dynamic graphics in the field of visualization. Dynamic graphics are visual displays via a sequence of changing images or animations (Becker, et al., 1987). Like the early film technology, by playing a series of static graphics, users can more intuitively perceive the changing trends or different perspectives in high-dimensional data. Examples of applications include time series, two-dimensional representations of high-dimensional data, visualization on sampling techniques, and so on. For time series data, ordinary static graphics can only display univariate continuous data. If multiple dimensions need to be displayed simultaneously, then each frame can only represent a specific time point. Dynamic graphics, on the other hand, can animate multidimensional data along the time dimension, thereby showing the trends over time. When visualizing high-dimensional data, one challenge is to project high-dimensional data onto a two-dimensional plane. Classic dimension reduction methods have to select optimal projection directions, but dynamic graphics like Grand Tour enable exploration of data by continuously rotating the projection direction (Cook, et al., 1995). Dynamic graphics can also be used to demonstrate sampling techniques by playing static graphics of different random samples, to help students understand concepts more easily in statistical education (Xie, 2013).

Interactive graphics refer to visualizations that allow users to adjust and optimize graphic parameters based on specific needs and highlight interesting areas to gain more effective information perception (McDonald, 1982; Theus & Urbanek, 2008). Modern internet technologies have transformed data visualization from the traditional format where researchers deliver information to users, into a new evolved model that users interactively explore data and customize views from a visualization tool. Common techniques in interactive graphics include selection, deletion, linking, brushing, rotation, scaling, etc. (Cook, et al., 2007) For instance, modifying the bin width of a histogram enables users to shift focus between the overall shape of a numerical variable and local details such as zero values or outliers. Similarly, highlighting a small subset of data points and observing their locations across other variables facilitates deeper understanding of the relationship between variables. An interactive data visualization platform can provide guided graphical options tailored to specific projects and datasets. Users can select datasets, observations, variables, parameters, etc., based on their topics of interest, to generate the optimal static and dynamic graphics that support decision-making. Examples of successful interactive data visualization software include commercial tools like Tableau and PowerBI, as well as open-source software such as R Shiny, Python Dash, and Plotly (Sievert, 2020).

2.2 Data-driven decision-making in digital government

The core values of open government data guide data-driven decision-making in digital government in collaboration with and among organizations and individuals in society. These values are transparency, accountability, and collaboration (Chen, 2017, Ch. 4 on open government, see below). Transparency is about making relevant public policy and service data available to the public. Democratic accountability directs the opening of government data on policies and services to the public. Open government data also creates resources and collaborative opportunities for society, inclusive of organizations and individuals (Janssen, et al., 2015).

Making government data open and available is the first and necessary step to foster transparency, accountability, and collaboration. In the United States, the Data Accountability and Transparency Act of 2014 provides the legal foundation and mandate for the federal government to make data available online. Government can open information and data in three areas to foster transparency: decision-making information such as government procedure, public policy and service data such as budget, and outcome information such as impacts of government expenditure on employment (Grimmelikhuijsen and Welch, 2012).

Government data transparency enhances accountability. Transparency of government policy and service data helps reduce corruption and make the government more accountable (Bertot, et al., 2010). At the local level, the availability of government service information such as the open government data portal for the city of Chicago provides citizenry with information on the variety of government services provided to various districts and neighborhoods. Residents and representatives in these neighborhoods can hold governments accountable for their actions.

Opening government data enables collaboration between government and organizations and individuals in society to create gains in efficiency and effectiveness (Matheus, et al, 2020 and Janssen, et al. 2015). In the United States, the publication of census data and GIS data by the federal government enables citizens and businesses to leverage the government data for economic and efficiency gains. Another mechanism is to have competitions such as hackathons for societal members to create applications leveraging open government data to provide new or improve current public services. The City of New York in the U.S. and the City of Shanghai, China have had annual competition events for such collaboration (Chen, 2017).

Moreover, data science and data visualization for data-driven decision-making enhance the quality and impact of open government data (Matheus, et al. 2020 and Ansari, et al, 2022). The recent advancement in artificial intelligence provides the machine-learning opportunities to analyze a large amount of data to advance public policy-making and public services (Charles, et al., 2022 and Valle-Cruz, et al. 2022). Interactive data visualization enabled by data analytic tools provides organizational and individual users to find answers to public policy and service questions. In addition, such a tool is also used for collaboration between government and citizens in prioritizing government resources such as seen in the area of participatory budgeting at the local level.

Data science and interactive data visualization can advance the values of transparency, accountability, and collaboration that are central to open government data. The use of 311 systems for some major U.S. cities provides residents the ability to track their government service requests and be informed of the local government services for accountability and transparency. The use of data dashboards can enhance collaboration and services such as the 'Waze' app using data from both government and citizens for the City of Rio de Janeiro (Matheus, et al., 2020). The National Science Foundation in the U.S. also has a data dashboard for institutional-based search and analytics to provide useful information.

There are significant opportunities to enhance the usability and use of data visualization to improve the use and usefulness of open government data (Ansari, et al., 2022). These opportunities lie in utilization of qualitative techniques for needs assessment and the involvement of user groups to provide evaluation and input (Ansari, et al., 2022). Acting on these recommendations, our study takes a co-design approach for the development, implementation, and evaluation of the interactive data visualization dashboard.

3. Enabling Visual Exploration on the Cyberinfrastructure Data

3.1 History of the government-funded cyberinfrastructure programs

TeraGrid, XSEDE, and ACCESS are a sequence of CI programs that were funded by NSF. Before TeraGrid, NSF had awarded several programs for large-scale computational infrastructure, including the National Computational Science Alliance and National Partnership for Advanced Computational Infrastructure (NPACI). TeraGrid, operated between 2001-2011, was the earliest distributed terascale facility that coordinated distributed high-performance hardware infrastructures with integrated scalable software and high-speed internet (Reed & Berman, 2001). XSEDE, running between 2011-2022, offered a more powerful virtual organization to provide the dynamic distributed infrastructure and services to scientific researchers (Towns, et al., 2011). ACCESS began in September

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

2022 and aimed to provide an agile, integrated, robust, trustworthy and sustainable CI ecosystem for computational- and data-intensive research (Boerner, et al., 2023; Parashar, et al., 2022).

3.2 Data platforms for ACCESS and historical programs

To monitor the services provided by the CI ecosystem, the NSF Office of Advanced Cyberinfrastructure funded the development of the XSEDE Metrics on Demand (XDMoD) auditing tools to measure the CI usage and performance metrics on XSEDE allocated resources for the current and historical project data (Furlani, et al., 2013; Palmer, et al., 2015). The XDMoD portal provides graphical user interfaces of data metrics like service units charged, number of jobs, etc. broken down by principal investigator, field of science, institution, resource, and so on (https://xdmod.access-ci.org/)(Palmer, et al., 2015) . For public users, this dashboard provides two tabs: the "Summary" page contains seven plots to display the aggregated usage, measured by computing or cloud resource, CPU hours, job size, etc. The "Usage" page contains more than 120 subpages of plots and data tables, showing the detailed data about jobs, allocations, requests, etc. with the total summary and breakdown numbers at multiple levels. On both pages, users can select a certain time interval and filter the data with 21 service providers.

Besides the XDMoD data platform, the ACCESS program developed its own interactive dashboard to display the geographical distribution of the allocation and usage data on their website (https://allocations.access-ci.org/geo#3.4/38.88/-111.01). On this dashboard, users could see the names and locations of research institutions with the amounts of resource credit allocation and usage, the names and locations of resource providers with the total amounts of used resource credits, and the connections between research institutions and resource providers. By hooking a certain institution, a few arch curves appear to link the institution with the resource providers they used. Reversely, when clicking a resource provider, the dashboard will show linkages to all institutions that are utilizing the service from this provider. With this dashboard, users could learn the usage preference of PIs from given institutions and reveal how the resource providers are supporting the research community.

The two visualization dashboards for the NSF CI programs were developed to facilitate data communication between service providers and resource users. However, both have their own limitations. The XDMoD user interfaces aim to provide a comprehensive view of a large database, requiring it to include and describe every variable, as well as the basic information about each. Even with only the first level of breakdown and without deeper branching, this tool has generated hundreds of pages, which results in an overwhelming amount of information for normal users. For researchers seeking to answer decision-making questions, current visualization platforms offer only basic statistics, like the total allocation units used by a specific institution or field of science. However, they lack the capability to show further interactions between variables. For instance, given a certain group of institutions, what are their strong fields of science regarding the used amount? Do they have some PIs with low usage rate who may need additional help? The ACCESS map platform focuses on showcasing the breadth and impact of the ACCESS program. It displays the total allocation and used amounts by institution and resource but does not offer data details for in-depth analysis.

3.3 Understanding needs from service providers and users

The focus of this study is how to help service providers, i.e., policy makers, understand and utilize data to optimize the operation of the CI ecosystem and solve existing problems. Our team's previous research has explored problems related to the fair allocation of resources and improving resource utilization efficiency. Chen, et al. (2021) built models to identify factors that influenced usage-allocation ratios and compared the ratios across different fields of sciences. In subsequent research, our team interviewed some leaders of the XSEDE program and learned that one of the issues that service providers are interested in is how to raise awareness, interest, and participation among scientific researchers with HPC needs. Hence the target group of this study has expanded from solely service providers to include both service providers and resource users.

From the perspective of service providers, they want to understand whether the training services they provide, such as the Campus Champion program of TeraGrid and XSEDE, are actually effective. Since NSF training projects are usually awarded based on institutions, and different institutions may also offer various computing services independent of NSF, resource utilization based on institutions is more likely to be influenced by decision-making compared to utilization based on a field of science. Therefore, the data visualization platform created by this work will provide service providers with data breakdown and summaries by institution. This will not only help computing centers participating in the NSF CI programs, but also those institutional computing centers to identify users' needs, discover trends, solve problems, and improve service quality.

For resource users, the journey from being unaware of CI projects to generating resource usage involves multiple barriers. First, researchers with HPC needs usually take the initiative to explore existing computing services. They may discover various resources. If NSF's CI program like XSEDE or ACCESS is not the only available option, then researchers can choose the service with the highest input-output ratio for their demands. Therefore, NSF's CI

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

program needs to enhance their promotion of advantages, such as high performance, low cost, and convenient services, to attract users. Next, when researchers become interested in NSF's CI program, they often want to learn about successful cases. If these successful examples are relevant to their own research projects, these potential users can be more motivated. Once they proceed to the application and usage process, when any procedural or technical problems or obstacles arise, whether there exists assistance support from easily accessible helpers to clarify and solve difficulties will significantly impact their user experience.

Moreover, resource users could be divided into the earlier established advantage groups and the emerging, late starter groups. The advantage groups include research teams led by the top experts in their fields, well-funded, research-intensive large institutions, and researchers who joined early in the TeraGrid program or have been using CI resources for years. The starter groups include rising stars in their fields, researchers from small to medium-sized universities with limited support for research activities, first-time CI project applicants, under-represented minority groups, and so on. The advantage groups are often familiar with the application and usage processes, so they do not need much help. However, the starter groups will need extra assistance, otherwise they are more likely to quit the competition when faced with difficulties.

Summarizing the needs of resource users, we believe that they need successful application examples or potential collaborators, as well as helpers to guide them on how to use CI services and hence accelerate their learning process. Traditional decision-making models may select only a few successful cases to inspire all users, but in the data era, the selection of successful examples can be data driven. This approach can filter and match the most suitable success cases for help seekers, based on the same field of science, institution, region, or similar research topics. This study will establish a data visualization platform to provide scientific researchers who need support with recommended potential collaborators and helpers.

3.4 Needs-based visualization design system for decision-making

In this study, we implemented a needs-based design framework to develop an interactive visualization dashboard for decision-making (Fig. 1). This system begins with identifying the specific needs of decision makers. They will then collaborate with domain experts to clearly articulate their needs and the underlying reasons. Domain experts would validate these requirements with decision makers and then find relevant data or collect data by themselves. Once the data is obtained, it is transferred to data experts for filtering, processing, exploration, and visualization. This stage often involves close communication between data experts and domain experts to understand and solve problems in the data. After reviewing a series of static graphics, data experts, guided by domain experts' insights, will gradually refine their ideas to determine which visuals would be most suitable for interactive features, to ensure the final visualization product effectively supports decision makers in exploring the data independently. Finally, data experts complete and deliver the interactive visualization dashboard to decision makers. Decision makers then provide feedback to both data experts and domain experts, to facilitate the debugging, updating, and improvement of the visualization tool.

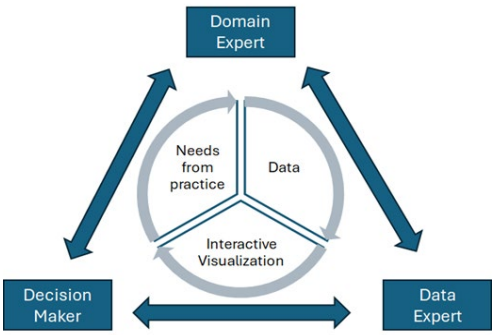

Fig. 1 – Needs-based visualization design system.

4. Data, Application, and Examples

The TeraGrid and XSEDE data are publicly available at the Illinois Data Bank at the University of Illinois at Urbana-Champaign. There are two databases for the allocation award and usage data: the XSEDE (2020) database includes data from the start of TeraGrid in July 2003 to December 2019, while the Towns & Hart (2023) database offers the same data features covering the period from July 2011 to the end of XSEDE in September 2022. Each database consists of two data files: one for awarded CI projects, which includes variables such as grant number, principal investigator (PI) name, institution, field of science, project type, transaction type, project title, abstract, and project start and end dates; and another for detailed resource-level usage information, including variables such as grant number, resource name, transaction type, allocation, used amount, and usage start and end dates.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

4.1 Data cleaning and preparation

The two databases were merged as shown in Fig 2. Since the period between July 2011 and December 2019 has overlapped, this segment was excluded from the earlier database. Subsequently, the data from 2003–2011 in XSEDE (2020) was combined with the 2011–2022 data from Towns & Hart (2023). The complete dataset retains two separate files: one for awarded projects and another for resource usage.

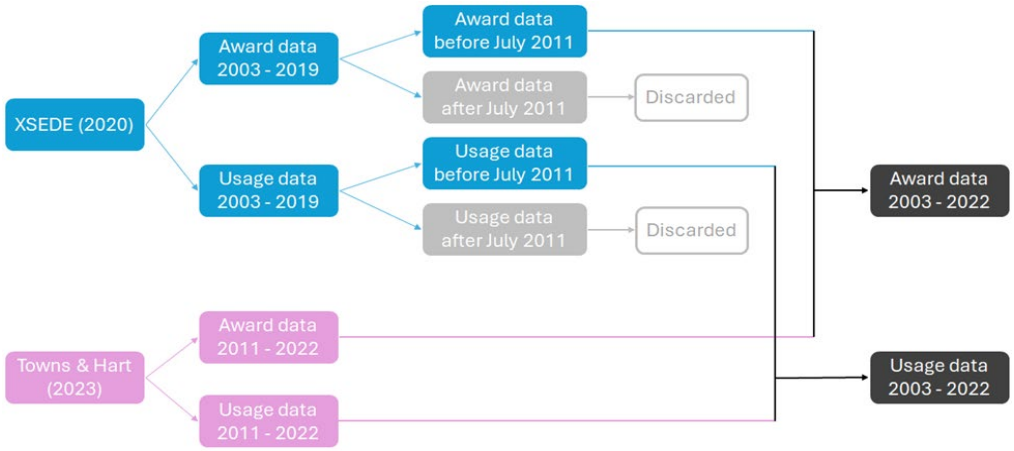

Fig. 2 – Data merging process for two databases, to generate the complete datasets for TeraGrid and XSEDE projects between 2003 and 2022.

The award data comprises 25,798 rows for 16,038 unique grant numbers by 10,277 PIs from 1,044 organizations. The program's peak period occurred between 2016 and 2020, during which nearly 2,000 projects were awarded annually. The usage data includes 85,827 rows covering 16,450 unique grant numbers and 123 unique resource names. Over the 19-year period, the total allocation exceeds 19.5 billion Service Units (SUs), while the total usage surpasses 15.6 billion SUs.

The next step was to merge the award data and the usage data to link the awarded projects with their allocation and usage information (Fig 3). Among the 16,038 unique grant numbers in the award dataset and the 16,450 in the usage dataset, 15,529 grant numbers appeared in both and were retained in the final merged data. The biggest challenge in merging the two data files was compressing information from multiple rows into one row per grant number. While some information about PI and project were duplicated in multiple rows, other variables could have different values for the same grant number. These included fields of science, project types, transaction types, start and end dates, resource names, allocation amounts, used amounts, etc. To resolve this, simple business rules were applied to aggregate the values, such as selecting only one field of science, project type, and transaction type for each project, using the earliest date as the start date, and summing the allocation amount and used amounts from multiple resources. In addition, novel variables were created for each awarded project, such as the number of fields of science, the number of resources utilized, etc.

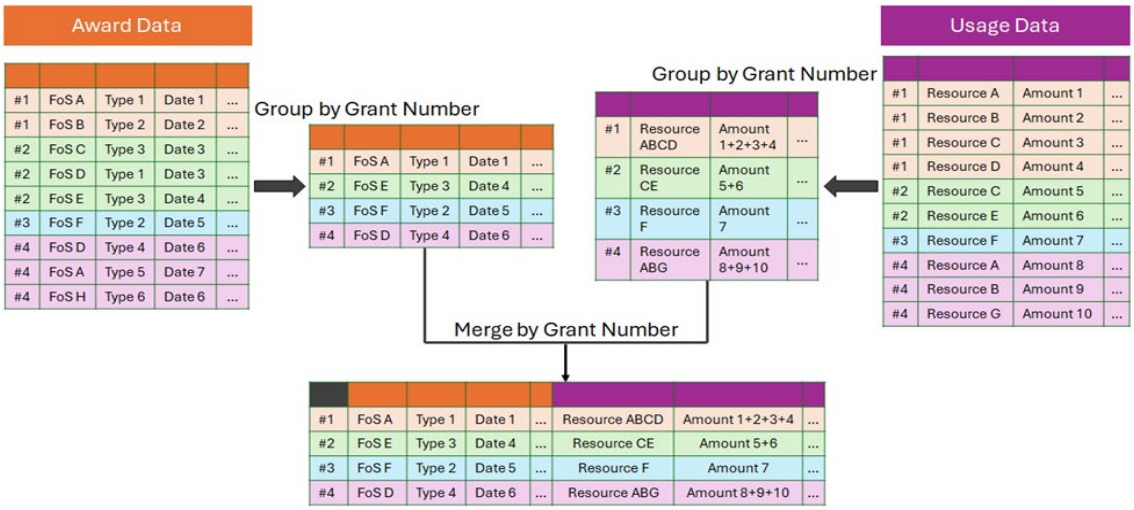

Fig. 3 – Data merging between award and usage datasets. Each row represents one grant project in the merged dataset.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

The final step in data cleaning and preparation was to add more useful variables from external data sources, including the longitude and latitude of each searchable organization, generated by the OpenStreetMap API (OpenStreetMap Contributors, 2017), and the Carnegie classification of U.S. institutions published by the Indiana University Center for Postsecondary Research (2021).

4.2 Design and functionality of the interactive dashboard

The interactive visualization dashboard created by this study (https://unodatasci.shinyapps.io/eqci/) was designed with several R packages (R Core Team, 2024) including ggplot2 (Wickham, 2016), shiny (Chang, et al., 2024), flexdashboard (Aden-Buie, et al., 2023), and leaflet (Cheng, et al., 2024). There are two pages for the two groups of decision-makers: an institutional view for the service providers and institutional computing centers, and a researcher's view for the potential service users.

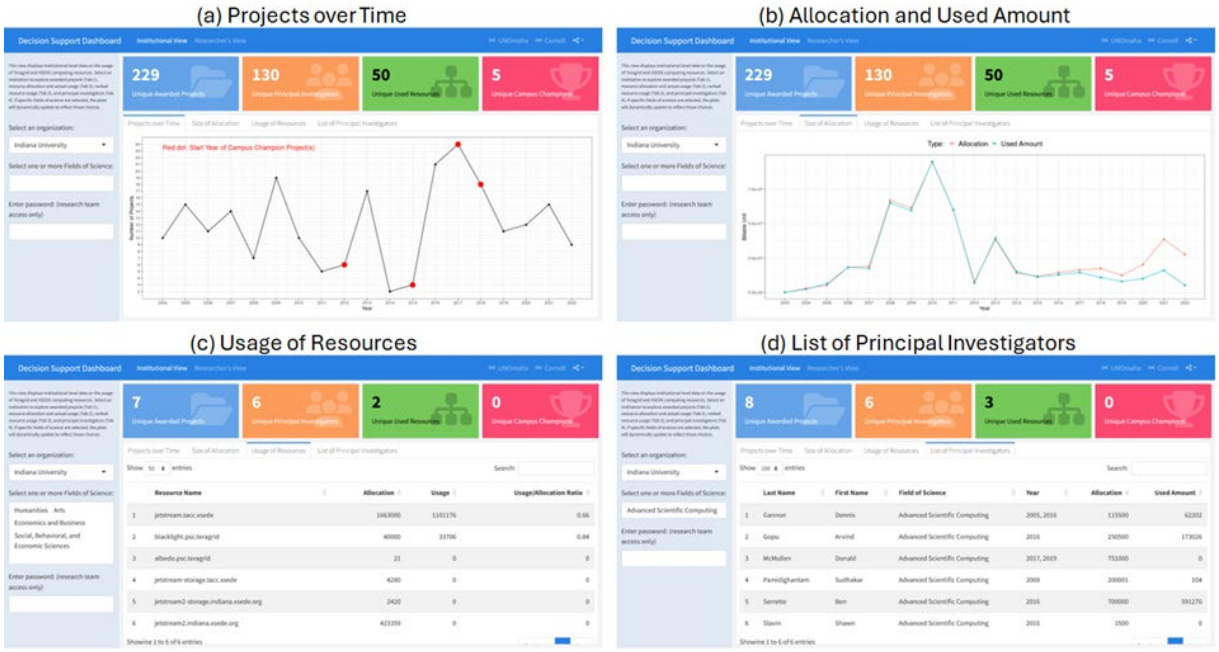

Fig. 4 – Institutional View of the dashboard with Indiana University as an example. Four tabs of visualization can be chosen: (a) Time series plot of the number of awarded projects by year. (b) Time series plot of allocation and used amount comparison. (c) Table of allocation amounts, used amounts, and ratios by resource name for the selected fields of science. (d) Table of the PI's names, fields of science, project start years, allocation, and used amounts.

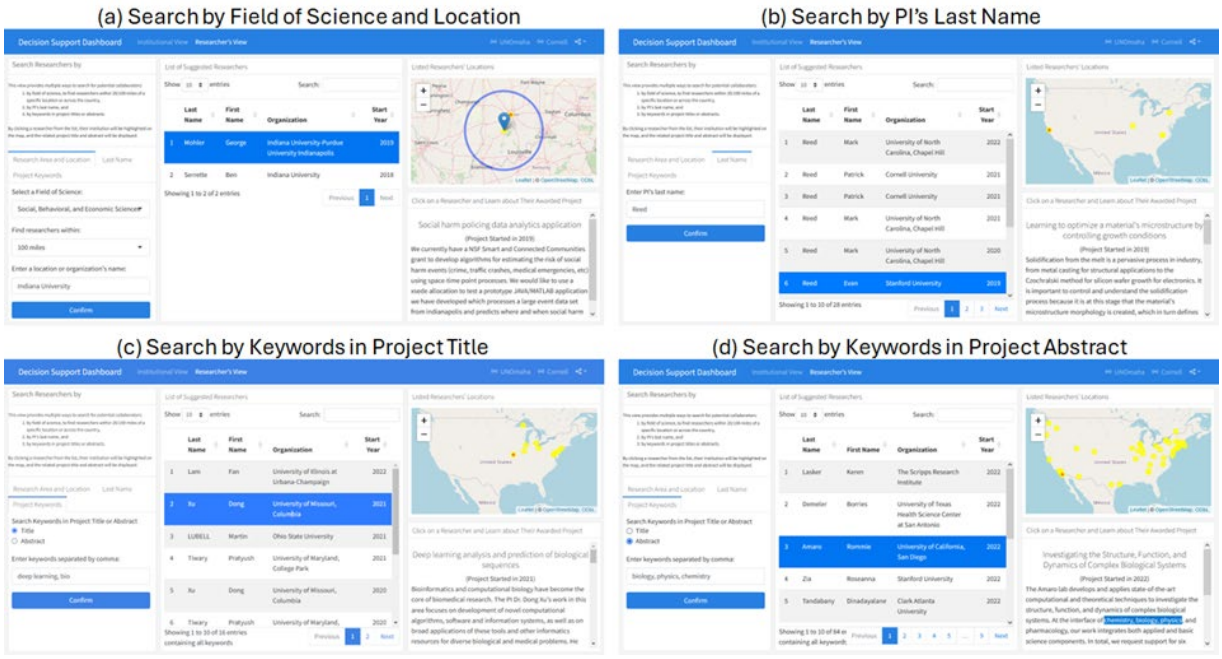
The design and functionality of the institutional view are shown in Fig 4. The page design includes a title bar, a navigation panel, four data boxes, and a graphical area. The title bar includes the title of the dashboard and the tab buttons of the two views. The left navigation panel contains a page introduction, two data filter boxes, and a password input area. With data filter boxes, users can select the institution and fields of science. This enables users to apply the intersection between the two and to compare results using the generated plots. The password input area is used to protect certain sensitive data, such as the usage rate for each PI. Only the specific research team can enter the password to view sensitive data for further analysis. Above the chart area on the right are four data boxes, representing four key data pieces: numbers of awarded projects, PIs, resource providers, and campus champions. Below the data boxes, users can click to select one chart page. Fig 4(a) shows the number of awarded projects from 2003 to 2022 for the selected institution and field(s) of science. Red dots represent years when the campus champion projects started. This plot helps service providers identify trends in awarded projects for the selected institution and determine whether campus champion projects contribute to an increase in XSEDE projects. Trends of development can be compared by selecting different institutions in the same field of science or the same institution in different fields. Fig 4(b) displays the temporal trends in total allocation (red) and usage (blue). For example, Indiana University's resource usage closely matched allocations from 2003 to 2017. However, starting from 2018 they began to diverge and by 2022, total usage only reached one-fourth of total allocation. These trends may motivate service providers to investigate the reasons behind such discrepancies. Fig 4(c) provides a breakdown of total allocation, used amount, and usage-to-allocation ratio by resource. The table is sorted in descending order of the used amount, but users can sort by allocation or usage-to-allocation ratio by clicking the respective column headers. For instance, four fields of science in Indiana University, including humanities, economics, social, behavioral, etc. had seven awarded projects but only two of the six allocated resources were used. Why these resources were underutilized could be investigated starting from the table. Fig 4(d) presents allocations and used amounts based on PIs. The usage-to-allocation ratio is hidden in this view. By setting

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

thresholds for allocation or used amount, service providers can identify PIs with high or low usage. If further combined with interviews to those PIs, more valuable insights will be obtained to help improve service effectiveness.

The design of researchers' view aims to assist late starters and potential applicants in finding PIs or mentors with successful CI experience in the same field, nearby locations, or with similar research topics. To support this, we provided four search methods: by research field and location, PI name, keywords in project title, and keywords in project abstract. Layout of this page is shown in Fig. 5: the left column contains a page description, search options, and search content settings. The middle column displays the search result of PIs, sorted by project start year from the most recent to the oldest. The upper right column features a map marking the locations of PIs. Clicking on a highlighted dot on the map will pop up the name of the institution, which can then be further used to filter PI search results by institution name. The lower right column provides detailed information about the awarded projects. By clicking on any PI row in the middle column, title and abstract of the corresponding project can be displayed for review.

Fig 5(a) illustrates how to find potential collaborators by the combination of field of science and user's location. The drop-down list for the field of science includes 215 fields from the XSEDE award data, allowing users to choose one area of interest. The search radius drop-down menu has three options: 20 miles, 100 miles, and “everywhere”, indicating the same city (20 miles), within a commutable distance (100 miles), or across the entire United States if no local collaborators are available (“everywhere”). Users can enter their location as a city name, institution name, or specific address in the location input box. After clicking the "Confirm" button, the dashboard will search for the location using OpenStreetMap and then mark it with a blue label on the map as the center of the search radius. Yellow dots on the map represent the locations of all PIs in the middle column list, while red dots indicate the locations of selected PIs. Fig 5(b) enables users to search for collaborators by entering a PI's last name, and the results list is sorted by project start year and displayed as yellow dots on the map. To narrow the search result, users can enter an institution name in the search bar of the table. Figs 5(c) and 5(d) allow users to search by keywords in project titles and abstracts. Users can enter one or more keywords, separated by commas, into the keyword input box. Projects that match exactly with all the keywords will be returned, and those that do not match exactly will be sorted by the number of matched keywords, with the top 20 displayed. This keyword search rule ensures users can identify PIs associated with relevant projects from recent years without being overwhelmed by an excessive number of results.



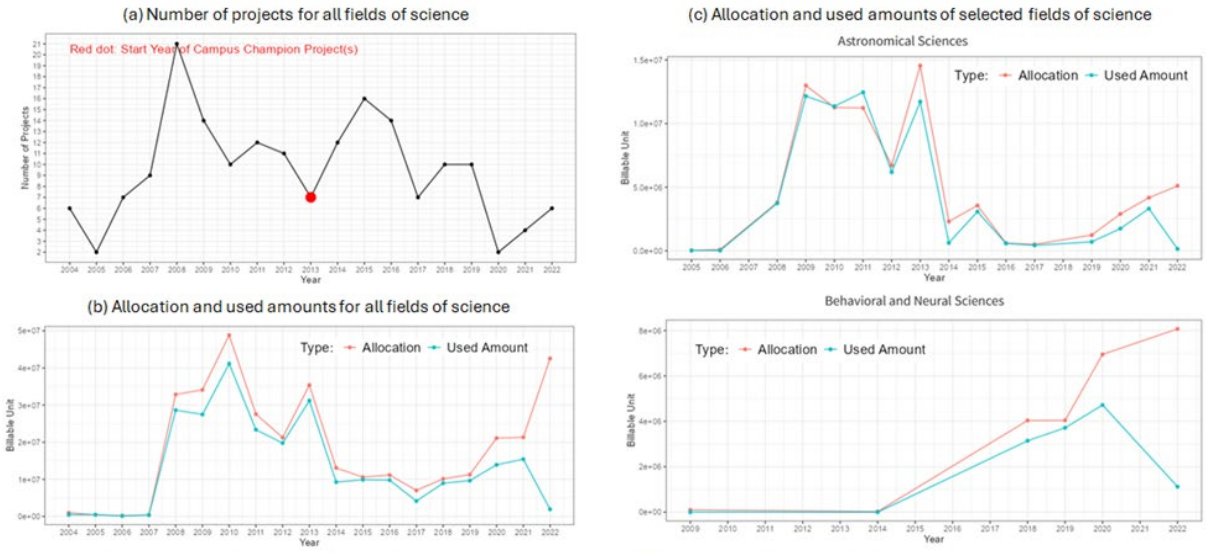


Fig. 5 – Researcher’s View of the dashboard. (a) Indiana University is the default searching location. Search radius was set to 100 miles, which generated a blue circle on the map. Clicking the first row of results will display the project title and abstract in the bottom-right panel. (b) By entering the last name “Reed”, a list of 28 PIs is obtained with their institutions, locations, and project information. (c) and (d) can match the keywords of interest, separated by commas, with the awarded project titles or abstracts, then corresponding PI names will be shown in the list.

4.3 Example demonstration on the dashboard

Three examples will be demonstrated to explain how the visualization dashboard can assist in decision-making.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Example #1 focuses on a research-intensive institution which also hosts a supercomputing center for the NSF CI program. Researchers at this institution naturally receive early and easy access to training on advanced computing services. We will examine whether any issues need to be addressed here. Example #2 highlights a late-starter institution, specifically an under-represented minority-serving institution. Following the 2021 Carnegie Classification definition on minority-serving institution as "Hispanic Serving Institution, Historically Black College or University, or Tribal College or University only," we matched institution names between the Carnegie Classification and CI data, and identified 96 institutions. One of these, with a moderate level of resource usage, will be explored. Example #3 considers a Midwest junior researcher in Social, Behavioral, and Economic Sciences. If this researcher seeks a potential collaborator or mentor in the field, we will demonstrate how the dashboard can be used to facilitate this search.

(d) Computing resources ordered by used amount

	Resource Name	Allocation	Usage	Usage/Allocation Ratio
1	ranger.tacc.teragrid	132786339	116234599	0.88

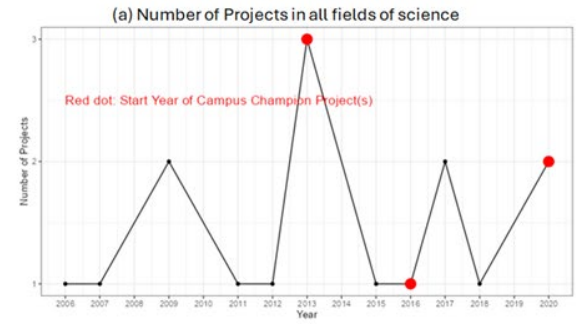

Fig. 6 – Data exploration for University of Texas at Austin. (a) Time series plot for the number of awarded projects in all fields of science. (b) Time series plot for the allocation and used amounts from all fields of science. (c) Comparison between two fields of science: Astronomical Sciences and Behavioral and Neural Sciences. (d) Top 17 computing resources ordered by their used amounts. (e) PIs with the highest used amounts.

Research-intensive institution. University of Texas at Austin (UTA) is the host of Texas Advanced Computing Center (TACC), which provides big convenience for computing resource users in the university and local area. By selecting the university name in the dashboard, users can obtain the plots shown in Fig 6 (a), (b), (d), and (e) from the Institutional View. Since 2004, UTA has received a total of 180 unique projects, including one campus champion project, involving 119 PIs. These projects have used 44 different resources. According to Fig 6 (a), the number of projects fluctuated over the years, peaking in 2008 before declining, and has remained at a relatively low level since 2020. Fig 6 (b) shows the changes in allocation and usage amounts over time. From 2008 to 2013, both allocation and usage were at their highest levels, followed by a decline between 2014 and 2019. After 2020, allocation increased again, reaching another peak in 2022. However, the used amount did not increase accordingly

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

but instead declined, which is a concerning trend. Fig 6 (c) compares UTA's two strong research fields: Astronomical Sciences and Behavioral and Neural Sciences. These fields reveal very different allocation and usage patterns. Astronomical Sciences used a large amount of resources from 2009 to 2013. In 2010 and 2011, the used amount was even higher than the allocation. But their usage dropped significantly after 2014. In contrast, Behavioral and Neural Sciences were relatively underdeveloped before 2018, with low project numbers and resource usage. However, after 2018, this field grew rapidly, with resource allocation steadily increasing. Fig 6 (d) compares the usage of different resources. The top three most popular resources all belong to TACC, and the leading resources generally receive high usage/allocation ratios. Fig 6 (e) lists the PIs with the largest allocation and usage amounts, along with their research fields. In some strong fields like Astronomical Sciences, UTA often has multiple PIs with awarded CI projects, and the usage/allocation ratios are relatively high. However, in fields with fewer PIs, such as Biological Sciences and Engineering Systems, the resource usage rate tends to be lower. This pattern suggests that internal collaboration within the research field may influence resource usage significantly.

Minority-serving institution. Florida International University (FIU) is a Hispanic-Serving Institution. Compared to other minority-serving institutions, FIU has a moderate level of experience with CI projects. Since 2006, the university has undertaken a total of 16 unique projects led by 10 PIs. As revealed in Fig 7 (a) and (b), FIU had no more than three new projects per year, and resource usage remained low for most years, except for a significant spike in 2018. This increase was driven by a Nuclear Physics PI who received an award that year (Fig 7 (d)). Most of FIU's allocations and resource usage came from the San Diego Supercomputer Center (SDSC), as shown in Fig. 7 (c). FIU's other strong research fields include computer science, earth science, and networking and communications, as indicated by the list of PIs with the highest resource usage. The usage-to-allocation ratios were below 0.5 for nearly all projects, except for three physics-related projects. Note that FIU received three campus champion projects in 2013, 2016, and 2020, all granted to the same PI. The first two projects were in the field of training, while the third was in physics. However, the allocated resources for these projects were ultimately not utilized, raising questions about the effectiveness of the campus champion projects for this institution.

Junior researchers or potential resource users. A junior researcher in the Midwest may face challenges finding a local collaborator in Social, Behavioral, and Economic Sciences who uses computing services frequently. In states like Nebraska or Iowa, there may be no such collaborators within 100 miles. To address this, the researcher should first select "everywhere" in the Researcher's View (Fig 8(a)) to check the locations of researchers. This reveals some potential collaborators near Chicago, making it a suitable search location (Fig 8(b)). The map highlights three universities: the University of Chicago, Northwestern University, and the University of Wisconsin–Milwaukee. The dashboard would also list corresponding PI names from these institutions. At Northwestern, one researcher specializes in large network modeling and has been awarded four CI projects between 2015 and 2019. The University of Chicago has a researcher in socioeconomic modeling, while Wisconsin-Milwaukee has one studying CEOs outside directorships. If none of these projects meet the junior researcher's interests, she can expand the search to nearby regions, using "Indiana" or "UIUC" as the search location. If choices in the Midwest are still too

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

limited, then keyword-based searches can help. Searching "government" yields two results in project titles (Fig 8(c) left) and 176 in abstracts, with locations shown on the map (Fig 8(c) middle). Clicking on a location, such as the University of California, Los Angeles, allows further exploration of potential collaborators at this institution and details of their research projects.

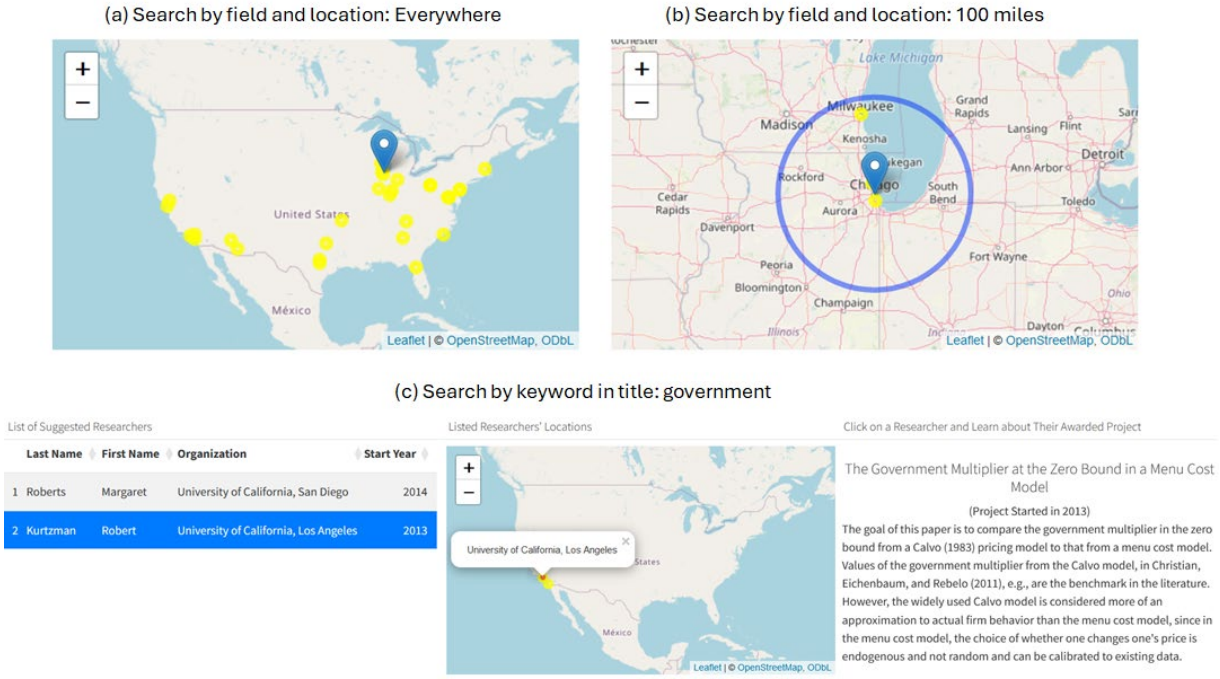

Fig. 8 – Searching for collaborators using multiple approaches. (a) and (b) used Chicago as the location and Social, Behavioral, and Economic Sciences as the field, with different search radius settings. (c) used "government" as a keyword to search project titles, yielding two results.

Through these three examples, we hope the interactive visualization dashboard users can learn how to effectively utilize the graphs and tables to search for useful information, identify potential issues, make comparisons, and support their decision-making process.

5. Conclusions and Future Work

This research reviewed the historical development of data visualization and its applications in the digital government domain, proposed a collaboration model among decision makers, domain experts, and data experts, and applied the model to the field of advanced research computing. Since 2003, the U. S. government has funded cyberinfrastructure programs such as TeraGrid, XSEDE, and ACCESS to promote scientific discovery. These programs have generated a large amount of data on the awarded projects with their resource allocation and usage. However, existing visualization tools for these data were not designed for in-depth analysis or direct decision-making support. This study investigated the needs of resource providers and users, analyzed the data collected from TeraGrid and XSEDE projects (2003-2022), and developed a publicly available interactive visualization dashboard. This dashboard enables resource providers and users to independently explore data through graphs and tables and make informed comparisons and decisions. In addition, this study demonstrates the practical application of the dashboard through three examples: a research-intensive institution, an under-represented minority-serving institution, and a junior researcher from a specific field of science. These examples highlight how data visualization could support and enhance decision-making. A broader impact of this study is the introduction of a collaboration model that does not only apply to the cyberinfrastructure and advanced computing area, but also to other digital government fields that generate and utilize data.

There are some shortcomings in research design and data processing procedures. First, when designing this visualization tool, our perspective mainly focused on the specific needs of CI service providers and potential users: to identify user groups with successful experiences, analyze their models, connect them with the groups who could benefit from these proven models, and improve the service of resource providers within the entire network. However, we may have overlooked the other needs of these two groups, or needs of other groups, such as the long-term, high-ability users of CI services. Second, the data aggregation step combined multiple rows of data into a single row based on the grant number, to merge award data and usage data (Fig. 3). This process resulted in some information loss. For example, a campus champion project may be renewed several times over years after the

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

initial award. However, since the grant number remains the same, the data merging process kept only the most recent renewal and removed all the previous records. As a result, it is impossible to visualize whether this campus champion project has been supporting other projects of this institution in early years or not. If the resource usage pattern of a project changed before and after renewal, the data merging approach would also obscure the information. Third, due to the limitations of the shiny package itself, the user graphical interface of our platform may appear differently on different web browsers or operating systems. The display on mobile devices, such as smartphones, may not be convenient for users to operate.

In the future, the interactive visualization dashboard will be improved in two aspects. From the data perspective, this platform currently only includes data from TeraGrid and XSEDE between 2003 to 2022 and does not involve data from the ACCESS program. We will use the XDMoD API to extract more detailed job-level data generated by ACCESS users when submitting job requests and receiving output from computing resources. This will help identify potential barriers and problems that resource users may encounter during their usage. From the user experience perspective, we plan to interview researchers from different types of institutions to better understand their actual needs. We will have them test the visualization dashboard and improve the design and functionality based on their feedback. Additionally, we will promote the dashboard through workshops and other outreach efforts to expand its user group and serve more people for decision making with cyberinfrastructure data.

Abstract. Data validation is critical for ensuring the reliability of information in educational systems, particularly in the context of digital governance. In Brazil, fragmented student records across various governmental databases hinder the implementation of educational public policies that rely on massive, high-quality student data. One effective method for validating these records is cross-referencing data across different databases. However, textual data, such as student names, are often prone to errors, including misspellings. Applying overly strict validation rules may result in the exclusion of valid records, while too lenient rules may allow incorrect data to slip through undetected. This study addresses these challenges by proposing a new data validation methodology that uses the Levenshtein distance algorithm. The approach identifies an optimal similarity threshold by taking into account the capacity of the manual validation team since excluded students are manually verified as a subsequent step, allowing for a balanced solution. We applied this methodology to validate student data from the Sistema Gestão Presente (SGP), which manages around 7 million student records and integrated it with the Brazilian Federal Revenue database. Through two key experiments, we demonstrated how an optimal validation threshold could be determined by considering the manual validation team capacity. In this case study, we found an optimal 80% similarity threshold when the manual validation capacity is approximately 950,000.

Keywords. Data Governance, String Similarity, Educational Data Interoperability, Levenshtein distance, public policies.

1. Introduction

Data interoperability emerges as a fundamental concept in the current landscape, characterized by constant technological evolution and the increasing use of data across various sectors (McBride et al., 2022; Wimmer et al., 2018). Data interoperability is primarily defined as the ability of different systems and organizations to exchange, understand, and use data and information securely, efficiently, and in a structured manner. Sectors such as healthcare, education, government systems, and businesses increasingly rely on effective data integration and analysis processes to ensure data-driven decision-making.

In public policy management and implementation, data interoperability between different systems is key, enabling cross-referencing information from various sources (Campmas et al., 2022; Wimmer et al., 2018). However, this process faces technical challenges, such as the lack of data standardization, inconsistent communication protocols, and issues related to data trustworthiness (Almeida et al., 2020; Styrin et al., 2022). In education, these challenges are exacerbated by data fragmentation, often arising from different federative entities, which undermines the quality and reliability of the records used (Ali et al., 2019; Harron et al., 2017; Loureiro et al., 2021).

In this context, data validation is indispensable in ensuring that information is consistent and reliable. Validation is particularly critical in educational settings, where errors and inconsistencies can directly impact the effectiveness of public policies (Cohen, 2000). In Brazil, challenges related to the fragmentation of educational information hinder large-scale data analysis and the formulation and implementation of policies to address educational inequalities (Barbalho et al., 2022; Queiroga, Siqueira, et al., 2024; Tavares & Bitencourt, 2024). This fragmentation is inherent to the country's educational structure, where responsibilities are distributed across federal, state, and municipal levels, each managing their own educational networks and information systems (Costin & Pontual, 2020).

The decentralized nature of Brazil's educational system, while promoting local autonomy, creates significant challenges in data integration and validation processes (Arretche, 2004). School systems often operate with different technological infrastructures, data collection methodologies, and reporting schedules, making it particularly challenging to establish standardized validation protocols and achieve consistent data quality across all educational networks (Segatto et al., 2022). These challenges are further amplified by the substantial regional disparities in technological infrastructure and institutional capacity among different educational administrative units (Queiroz et al., 2020; Rocha et al., 2024; Wanke et al., 2024).

The Sistema Gestão Presente (SGP) was developed to centralize high school student information into a single, integrated system to address the challenges of integrating students' attendance data on a centralized system. This system aims to facilitate data cross-referencing and support the implementation of public policies focused on education, such as the Pé-de-Meia Program (PDM)[1]. Established by the Brazilian government in 2024 (Ministério da Educação, 2025b), the PDM is part of the pay-for-attendance programs and is a Conditional Cash Transfer Program, similar to the Mexican Progresa, a pioneering initiative that links financial incentives to school attendance and health checkups (Fiszbein & Schady, 2009; Kremer, 2003; Parker & Todd, 2017). The PDM provides financial incentives to public high school students to promote school retention, encourage the completion of their studies, and stimulate participation in the National High School Exam (Enem)(Ministério da Educação, 2025a), which was created in 1998 by the Anísio Teixeira National Institute for Educational Studies and Research (INEP).

The PDM operates based on enrollment, attendance, annual approval, and exam participation criteria. However, its effectiveness is heavily dependent on the quality of the data used. The SGP, which manages approximately 7 million unique student records, faces substantial challenges in data validation. Issues such as incorrect names, missing essential information, and registration inconsistencies undermine the database's reliability and hinder payment authorization, directly impacting students who depend on these incentives. These challenges emphasize the complexities of aligning large, heterogeneous databases and the critical need for robust technological solutions and rigorous methodologies to ensure accuracy and minimize student disruptions.

The present paper introduces a case study focused on improving the accuracy of student records in Brazil through data validation processes that leverage text similarity algorithms. The rest of this paper is structured as follows. Section 2 presents the related literature about interoperability in governmental systems and the use of similarity algorithms to improve data quality. Section 3 of the paper details the student data validation process implemented by the SGP, focusing on ensuring data reliability and accuracy under ideal conditions. Section 4 illustrates the proposed approach for the problem of students' data validation. Section 5 describes the experiments conducted to suggest the threshold similarity for validating the records. At last, Section 6 discusses the work results, and Section 7 concludes the paper.

[1] Pé-de-meia is a Brazilian expression that refers to money saved for future use

2. Literature review

Data validation and interoperability are fundamental pillars for efficient information management in government systems. Developing data interoperability platforms that facilitate data exchange, validation, and utilization is a critical priority in the digital transformation of governments (McBride et al., 2022). These efforts represent a significant step toward unifying the databases of complex systems, particularly those in key sectors such as education, health, and governance (Das et al., 2022; Malodia et al., 2021; Saffady, 2021; Styrin et al., 2022).

The challenges in these sectors, such as high data fragmentation and the lack of standardization, pose significant obstacles to the implementation and monitoring of effective public policies (Almeida et al., 2020; Queiroga, Siqueira, et al., 2024; Styrin et al., 2022). Specifically in education, these issues become even more evident due to the high variability of records and the need to integrate local, state, and federal systems (Ali et al., 2019; Almeida et al., 2020; Harron et al., 2017; Loureiro et al., 2021). In Brazil, legislation structures different federative levels of responsibility over public education, fragmenting data on enrollment, attendance, and performance among thousands of municipal, state, and federal education departments. This variability alone presents a significant challenge in the creation of data interoperability platforms, as data often follow different standards or include minor inconsistencies at the source, such as missing surnames or their abbreviations (Almeida et al., 2020; Queiroga, Santana, et al., 2024). Techniques like the Levenshtein distance and the Jaro-Winkler distance effectively address these inconsistencies, ensuring greater reliability in the records (Almeida et al., 2020; Handijono & Suhatman, 2024; Loureiro et al., 2021).

Thus, several authors demonstrate how data interoperability can yield significant results in knowledge discovery and supporting decision-making processes. Queiroga, Siqueira, et al., 2024 proposes a model for extracting key factors from the interoperability of educational data in Brazil. To achieve this, factor analysis techniques are applied to identify eight main factors related to structural equity in the educational system, aiming to provide personalized recommendations supporting digital governance and formulating context-specific public policies. However, the absence of unique identifiers posed a significant challenge, limiting the practical application of the research, particularly in addressing the needs of specific student groups.

In this context, the search for techniques that can help to identify degrees of integrated different databases and enable more automated data validation has been widely explored. One of these methods is string similarity (Kaufman & Klevs, 2022). Entity matching is another recurring challenge in systems aiming to integrate data from different sources. Sakai et al., 2021 investigated the combination of string transformations and similarity metrics to consolidate duplicate records. Similarly, Handijono and Suhatman, 2024 applied the Jaro-Winkler technique to identify strings with a high degree of similarity for detecting duplicate data in records. This approach seeks to optimize databases by reducing inconsistencies and redundancies. By clustering similar records based on names and registration data into single entities, the authors achieved satisfactory results in minimizing data duplication and improving data consistency.

Research on the use of semantic embedding models has also advanced progress. Asadollahi et al., 2024 demonstrated how models adapted to specific contexts can accurately capture textual and semantic nuances. In their study, the authors used construction data to train models aimed at improving the identification of semantic texts, with a focus on data interoperability between different systems and the development of a standardized data pipeline. The results indicate that techniques based on adapted string decomposition outperformed traditional methodologies and even advanced language models while maintaining a significantly lower application cost.

Data modeling, in turn, requires flexible approaches to address the diversity of contexts. Kouremenou et al., 2024 found that among 100 healthcare institutions participating in their study, 23 experienced data management or interoperability issues over the past five years. To address this, the authors proposed a generic and accessible framework designed to facilitate data exchange and mapping. This type of tool proved particularly useful for integrating data from systems where the lack of unified standards often creates redundancies and inconsistencies, enabling interoperability through data modeling prior to transfer.

Similarity metrics, such as TF-IDF and cosine similarity, also play an important role in data validation (Cohen, 2000; Downs et al., 2019). Gómez and Vázquez, 2022 conducted an empirical analysis of different similarity search methods within academic articles and theses. Their results showed that advanced techniques have a

significant computational cost, without this cost translating into substantially better outcomes. Conversely, simpler techniques, such as those based on distance measurement, achieved comparable results to advanced methods with a significantly lower computational cost. This is particularly noteworthy as the scalability of solutions becomes critical with the increasing volume of data. Machine learning-based methods offer promising alternatives but still face limitations related to record variability and computational expense. Tools that combine computational efficiency with analytical precision are increasingly necessary to meet the growing demands of governmental systems, especially in the education sector.

Practical approaches have shown significant results. Damasceno et al., 2021 presented SimClear, a tool that leverages similarity functions, such as Levenshtein distance, to standardize educational records during the data cleaning phase. This tool has been successfully applied to correct textual errors, increasing data reliability and reducing the need for manual review.

It is also worth noting that while recent advances in Machine Learning techniques and semantic embedding have significantly expanded the possibilities for data validation and interoperability, traditional methods, such as text similarity algorithms (e.g., Levenshtein and Jaro-Winkler), continue to deliver satisfactory results with a favorable cost-benefit ratio. This is particularly true in scenarios where computational efficiency, scalability, and simplicity of implementation are critical (Gómez & Vázquez, 2022).

3. Student Data Validation

Data validation in educational systems is critical to ensuring the reliability and efficacy of the information used to formulate public policies (Almeida et al., 2020; Cohen, 2000; Tavares & Bitencourt, 2024). The Brazilian educational system is highly decentralized, leading to fragmented data and posing challenges for managing and implementing centralized programs or policies. The data validation flow at SGP is an essential component to assure information integrity, and it was carefully designed to avoid inconsistencies, assure record accuracy, and ease the identification of errors. The general flow of data collection and validation at SGP is presented in Figure 1.

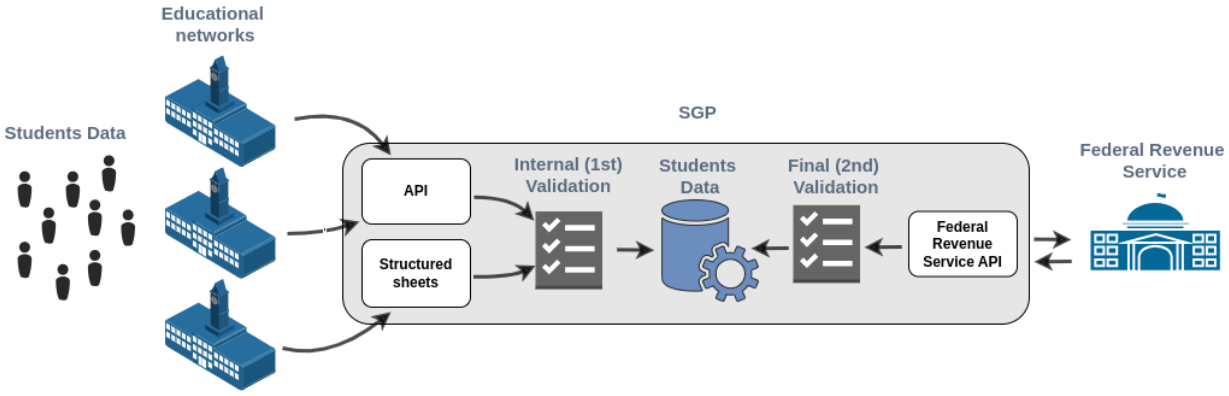

Fig. 1 – Data Validation Flow.

As seen in the figure, Educational networks (formed by the state, federal, and municipal entities) are responsible for initially submitting student data to the SGP through two methods: an integrated API for automated communication between their systems and SGP and direct submission of spreadsheet files on the platform. SGP administration encourages using the API to enhance security, improve efficiency, and reduce errors. However, as educational networks may not yet possess the required infrastructure for API integration, the submission of structured file sheets provides a viable alternative.

After receiving the data from educational networks, the system processes a first validation step that involves some basic verifications, such as ensuring the correct format of the fields, fulfilling all mandatory information, and identifying duplicates. Once verified, the data is preprocessed and stored in the system's database for the next validation stage. The tax identification numbers of students are then sent to the Federal Revenue Service of Brazil to verify consistency with government records.

The primary key for this validation with the Federal Revenue Service is the Brazilian Tax Identification Number (CPF, from the Portuguese Cadastro de Pessoa Física). The SGP sends the student's CPF to the Federal Revenue Service and receives the following information associated with him/her: day of birth, full name, and mother's name. These data are then compared to the information stored in the SGP database; if identical, the register is considered valid. This represents the ideal scenario where no additional intervention is needed. However, the decentralized nature of Brazil's educational system, combined with differences in data structure and update timeframes among educational departments, introduces substantial challenges. Initial checks already indicate an 11.97% inconsistency in student records, further emphasizing the need for robust validation methodologies. Thus, for those cases where only the date of birth coincides, but the full name and the mother's name present differences, we propose to apply similarity algorithms to assess the correspondence between the data.

4. Proposed Approach

Figure 2 provides a general overview of the proposed students' data validation approach. The process begins with data preprocessing, where names are normalized, abbreviations are standardized, and uniformity is ensured. This is followed by the data understanding phase, identifying patterns, inconsistencies, and duplicated or incomplete records. The output of these steps is fed into the similarity threshold evaluation, which is designed to learn the optimal threshold that ensures high validation accuracy, minimizes false positives, while still being tolerant to subtle differences in names that usually do not invalidate the identification of the students. The suggestion of a similarity threshold is possible after the conduction of two key experiments: (E1) Analyzes the impact of different similarity thresholds on the validation of records, considering both the student's name and the mother's name, to determine the optimal threshold (80% in our case study) for balancing accuracy and operational efficiency; and (E2) demonstrating the optimal threshold's ability to capture expected variations and to reduce matching errors.

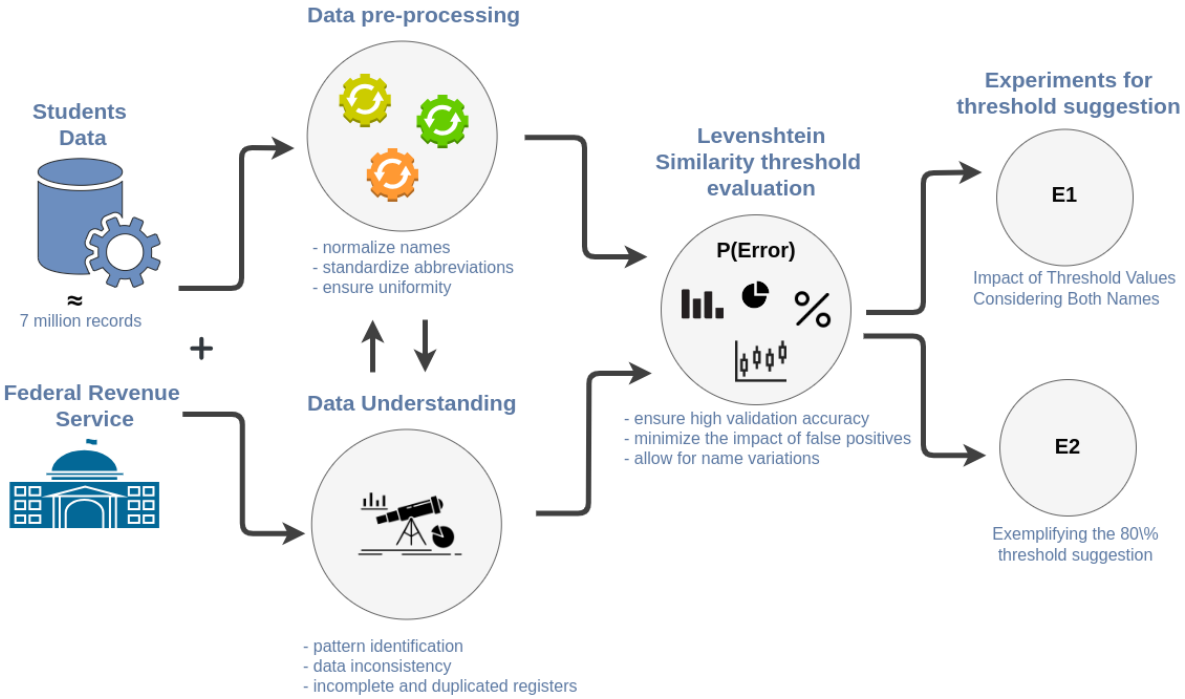

Fig. 2 – Approach followed for student's data validation.

Given two pairs of strings representing a student's name and their mother's name, extracted from two different databases (SGP and the Federal Revenue database), their similarity is measured separately using the Levenshtein distance algorithm. This helps quantify differences due to typos, formatting inconsistencies, or minor spelling variations, allowing for more accurate data reconciliation. If the data are completely identical, no alert is issued, and the student's registration is successfully validated. If the similarity rate equals or exceeds the minimum similarity threshold for both pairs, the record is classified as valid with an inconsistency alert, which is saved to enable future monitoring and auditing. If, on the other hand, the similarity rate of one

of the pairs is below the minimum similarity threshold, the record is classified as invalid, and an alert is issued on the SGP platform, notifying the education network to review and correct the submitted data (see Figure 3). This alert promotes continuous database improvement, preventing inconsistent information from hindering the program's progress.

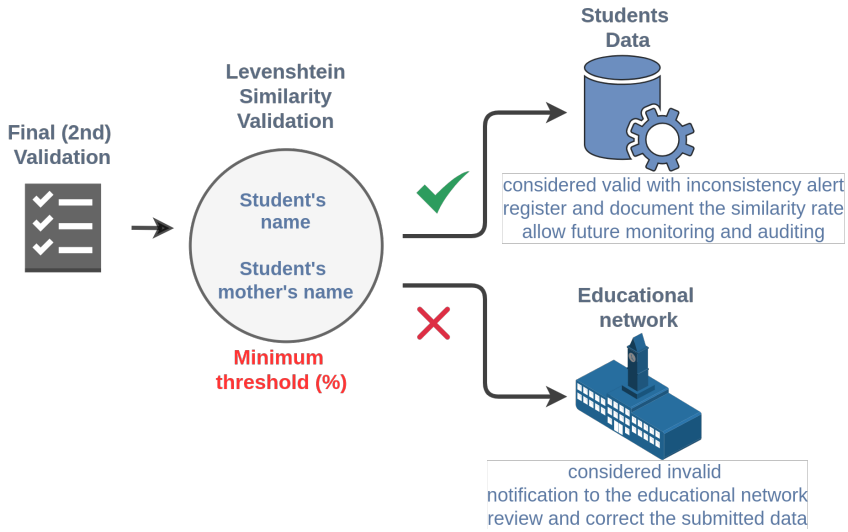

Fig. 3 – Using Levenshtein distance algorithm.

4.1. Data preprocessing and understanding

Data preprocessing was performed to ensure a standardized format for the data, minimizing the impact of irrelevant variations and increasing the precision of the similarity algorithm, as follows:

- Removal of accents and special characters to normalize the spelling of names.
- Standardization of abbreviations and removal of stopwords, such as "de," "da," and "do," which are common in Brazilian names and can interfere with similarity calculations.
- Elimination of extra spaces and conversion to lowercase, ensuring greater uniformity in the data.

Exploratory data analysis was conducted to understand structural features and underlying patterns existing in the data. The database, with approximately seven million registers of students from the high school level, presented a high variability in the names of the students and their mothers. The initial analysis focused on the frequencies of the most common students' names registered in the database. Around 5,73% of the students' full names correspond to records with a high probability of repetition; the top five most common names had 1,150; 685; 603; 582; and 405 occurrences, respectively. This high frequency of repetition in names highlights the possibility of ambiguities, making it difficult to distinguish unique records without using complementary variables, such as the date of birth and the mother's name.

In this sense, the probability of coincidences rate was estimated that approximately 7% of the students in the SGP database have a name that exactly matches another student's name. A similar percentage was found for mother's names. Consequently, the probability of a validation error when simultaneously considering a student's name and mother's name is estimated to be 0.49%.

A second challenge involves identifying students across different databases when their names exhibit slight spelling differences due to typographical errors, abbreviations, or orthographic variations. The analysis identified inconsistencies such as differences in accentuation (e.g., "María Eduarda" versus "Maria Eduarda"), standard abbreviations (e.g., "José Antônio" versus "José A."), and typos (e.g., "João Vítor" versus "Jão Vitor"). These variations complicate the process of reconciling records between databases and require robust similarity measures to ensure accurate data integration.

A correlation analysis was conducted among the variables available in the database to minimize false positives (acceptance of incorrect records) and false negatives (rejection of valid records) in validation. The date of birth

stood out as a robust variable less prone to errors, making it an excellent candidate for use as a reference point in validation. The combination of names and dates of birth proved effective in distinguishing duplicate records or identifying inconsistencies, particularly in cases of prevalent names. The analysis revealed the following most common problems related to data quality:

- **Empty fields**: Approximately 2.8% of the records lacked complete information about the mother's name.
- **Formatting errors**: Presence of special characters and multiple spaces in some records.
- **Duplicate data**: Around 0.9% of the records showed evident duplications, such as two entries with the same CPF and similar names.

The exploratory analysis provided a comprehensive view of the database's challenges and characteristics. The results highlight the importance of using additional variables, such as the date of birth, to enhance name validation. Observations on name repetition and spelling variations were crucial for fine-tuning the similarity algorithm and adjusting the matching threshold to improve accuracy. The analysis also underscored the need for data cleaning and standardization techniques to improve database quality and facilitate interoperability with other governmental systems.

4.2. Levenshtein Distance Algorithm

The Levenshtein distance algorithm, also known as edit distance, is a widely used technique for measuring the similarity between two strings. It calculates the minimum number of operations needed to transform one string into another, which includes insertion (adding a character at any position), deletion (removing a character from any position), and substitution (changing one character to another at a specific position) (Gómez & Vázquez, 2022; Ouarda et al., 2023).

For example, to transform the string *"cat"* into the string *"rat"*, only one substitution is required (changing "c" to "r"). In this case, the Levenshtein distance is equal to 1. To transform *"par"* into *"parallel"*, five insertion operations are needed, resulting in a distance of 5.

The calculation of the Levenshtein distance is based on a dynamic programming model, where a two-dimensional matrix is constructed to represent the cumulative cost of transforming prefixes of one string into another. The steps include:

1. Inicialization of matrix D of size $(m+1) \times (n+1)$, where m and n are the lenghts of the strings A and B, respectively.
2. Filling the boundary conditions:

$$D[i][0] = i \quad \text{and} \quad D[0][j] = j$$

   representing the cost of transforming a string into an empty one.
3. Iteratively filling the matrix using the formula:

$$D[i][j] = \min \begin{cases} D[i-1][j] + 1 & \text{(deletion)} \\ D[i][j-1] + 1 & \text{(insertion)} \\ D[i-1][j-1] + c & \text{(substitution, where } c = 0 \text{ if } A[i] = B[j], \text{ or 1 otherwise)} \end{cases}$$

4. The final value $D[m][n]$ indicates the Levenshtein distance between A and B.

The interpretation of the distance can be normalized into a percentage similarity metric, called *Edit Similarity* (EDS):

$$\text{EDS} = \left(1 - \frac{\text{Levenshtein Distance}}{\text{Maximum possible length between the two strings}}\right) \times 100$$

5. Defining the optimal similarity threshold

This work proposes a series of experiments to establish the optimal similarity threshold necessary for validating student records. These tests were aimed to tackle the following tradeoff:

- a higher threshold diminishes the probability of erroneous instances being validated, but requires a larger amount of manual checks - possibly for valid students.
- a lower threshold would increase the probability of erroneous instances being validated, but requires a smaller amount of manual checks.

Thus, we propose to consider as input the capacity of the manual validation team, since excluded students are manually verified in a subsequent step. The optimal similarity threshold is defined as the larger value that results in an amount of manual checks that can be handled by the manual validation team.

This approach allows the identification of an effective balance, ensuring that the system accurately identifies and corrects mistakes in student records without overloading the process with unnecessary manual checks. In this section, we describe two experiments performed on the SGP and Federal Revenue databases to test the effect of different thresholds and better understand how variability in the threshold influences the detection of potentially invalid records. Each experiment addresses a specific aspect of the issue, as follows:

- **Experiment 1 (E1):** Analyzes the impact of different similarity thresholds on the validation of records, simultaneously considering both the student's name and the mother's name, to determine the optimal threshold (80% in our case study) for balancing accuracy and operational efficiency;
- **Experiment 2 (E2):** Examines simulated examples from the database to demonstrate if the optimal threshold found in our case study for both attribute captures expected name variations, minimizing false positives and false negatives.

5.1. Experiment 1: Impact of Threshold Values Considering Both Names Simultaneously

This experiment was designed to investigate how different threshold values influence the validation process, assessing their impact on the rejection or acceptance of records. The initial goal was to calibrate a threshold that balances the number of invalidated records and the probability of erroneous instances being validated, while accounting for the variability of both the student's name and the mother's name, two critical identification variables in the Brazilian context.

For each record of the SGP database, we use its CPF as the primary key to retrieve its potential match record from the Federal Revenue database. Then, we perform a hard validation by verifying whether its day of birth, full name and mother's name are identical, in which case the SGP record is considered valid. Otherwise, it is considered for experiment 1, composing a subset named $\mathcal{M} = \{m_{,1}, m_2, \ldots, m_n\}$ that is comprised of pairs of records $m_i = (s_i, r_i)$, where s_i is a record from SGP and r_i is a record from the Federal Revenue database.

We aim to assess how many records in M are rejected based on a soft-validation process with varying threshold values. A pair m_i is considered soft-validated if it meets the following conditions:

1. the day of birth of s_i and r_i matches;
2. the EDS score for the student names in s_i and r_i exceeds the threshold;
3. he EDS score for the student's mother's names in s_i and r_i exceeds the threshold.

The methodology involved testing thresholds ranging from 60% to 100% in units increments.

Figure 4 shows the number of records rejected per threshold. As expected, lower thresholds (e.g. 60%-70%) resulted in fewer rejections but increased the risk of false positives, where inconsistent records were incorrectly validated. However, higher thresholds (e.g., 90%-100%) significantly increased the number of rejections, potentially leading to false negatives, where valid records were improperly rejected. To address this, we propose calibrating the threshold based on the capacity of the manual validation team, considering that it can handle a maximum of 950,000 manual verifications. This led to the selection of 80% as the optimal threshold for the student's name.

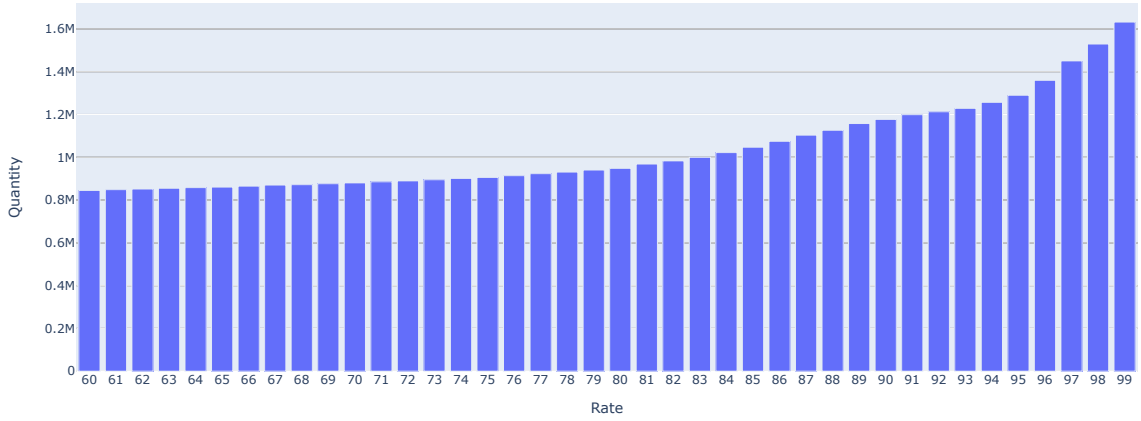

Fig. 4 – Amount of students that are invalidated for different thresholds.

5.2. Experiment 2: Exemplifying the 80% threshold suggestion

Experiment 2 was designed to illustrate, through practical examples, how the 80% threshold plays a crucial role in classifying records as valid or invalid. This experiment complements the quantitative analyses of the previous experiments by providing a qualitative and detailed view of how the model operates in real-world scenarios. The motivation for this experiment stems from the need to validate the suitability of the 80% threshold in real situations, highlighting representative cases where the choice of this value directly impacts the accuracy and scope of the validation process. Data such as the student's and mother's names are particularly sensitive to subtle variations, such as typographical errors, abbreviations, and marital status changes. Thus, understanding how the model handles these variations in real-world contexts is essential for refining its practical applicability.

To conduct this experiment, we present a simulated example and calculate the similarity between string pairs using the Levenshtein distance algorithm. Two cases were analyzed, representing scenarios of positive and negative validation, as described below:

- **Positive Example:** "Maria Eduarda da Silva Rodrigues" and "Maria Eduarda da Silva Rodigues" have a similarity of 96.43%, passing the 80% threshold. This high similarity is due to a single discrepancy: the absence of the letter "r" in the second "Rodrigues" last name. The Levenshtein algorithm identified this minimal difference as a substitution, resulting in a successful validation. This example highlights the robustness of the model in handling minor variations that do not compromise individual identification.
- **Negative Example:** "Maria Eduarda da Silva Rodrigues" and "Maria Eduarda Silva Antunes" have a similarity of 60.71%, falling below the 80% threshold and being rejected. The discrepancies include the absence of "da" and the substitution of the last name "Rodrigues" with "Antunes," totaling an edit distance of 11 characters. These significant differences justify the rejection of the record, demonstrating the model's sensitivity to variations that may compromise data integrity.

These practical examples reinforce that the 80% threshold provides an appropriate balance for capturing acceptable variations while rejecting more significant discrepancies that could compromise record integrity. Additionally, the examples highlight the effectiveness of the Levenshtein distance algorithm in identifying subtle patterns of difference, making it a suitable choice for applications in educational data validation.

6. Discussion

The results obtained in this study reinforce the importance of adequately calibrating the similarity threshold in educational data validation systems. The experiments demonstrated how an optimal threshold can be chosen quantitatively and qualitatively. The threshold value of 80% was capable of keeping the required number

of manual validations below 950,000 while maintaining robustness in the challenging cases presented in Experiment 2. This finding is particularly relevant for large-scale systems such as the SGP, which operates with a database of approximately 7 million records.

Based on the results of Experiment 1, the 80% similarity threshold was determined as the optimal balance between precision and recall. This threshold minimizes false positives by rejecting records with significant discrepancies while tolerating minor variations such as typos, abbreviations, and orthographic inconsistencies.

The effectiveness of using similarity thresholds above 70% in string comparison has also been validated in previous studies (Gali et al., 2019; Libuy et al., 2021; Yu et al., 2016). For instance, the work by Valeriano, 2024 tested different thresholds for string matching and consistently found the best results with values above 70%. This aligns with our findings, where the 80% threshold provided a robust trade-off between validation accuracy and operational efficiency.

Compared to the work of Libuy et al., 2021, our study highlights the scalability of the proposed approach. Reducing the similarity threshold from 99% to 80% resulted in a reduction of over 40% in the number of rejected records without compromising data integrity. On the other hand, in relation to the scope of operations discussed in Cohen, 2000, it was necessary to adopt stricter criteria to ensure that minor name discrepancies did not result in the acceptance of invalid records. This decision reflects the specificities of the educational context, where imprecise data can significantly impact the distribution of government benefits.

The choice of an 80% threshold also had a profound impact on the workload of the teams responsible for data validation. With thresholds lower than 80%, the likelihood of false positives increased, requiring additional manual checks to ensure data consistency. Conversely, thresholds above 80% rejected a greater number of valid records, creating an excessive demand for manual review. By adopting the 80% threshold, the system optimized human resources, allowing teams to focus on more complex cases instead of addressing minor inconsistencies.

Practical examples reinforced the effectiveness of this threshold. For instance, a similarity score of 96.43% successfully validated minor discrepancies (e.g., “Rodrigues” vs. “Rodigues”), while a score of 60.71% appropriately rejected significant mismatches (e.g., “Rodrigues” vs. “Antunes”). These results demonstrate that the 80% threshold ensures reliable validation without overburdening the system with excessive manual checks.

Additionally, the results demonstrate that the Levenshtein distance algorithm is a practical solution for the analyzed context, offering simplicity and computational efficiency. While more advanced techniques, such as machine learning, could provide higher accuracy, their computational cost makes them impractical for a database the size of the SGP. This highlights the importance of solutions tailored to operational constraints and the need for scalability.

Although the presented results demonstrate the proposed approach’s effectiveness, some limitations must be highlighted. The reliance on auxiliary variables, such as the CPF and date of birth, ensures accuracy but creates dependency. The absence or inconsistency of these variables can introduce challenges, particularly in regions with less rigorous data collection practices. Future research could explore complementary variables, such as school history or address data, to enhance the robustness of the model. In addition, the optimal threshold found in this work may not be the optimal one in other scenarios. Thus, we recommend conducting similar experiments to calibrate the threshold according to the manual validation team capacity, and perform qualitative experiments to assure that the optimal threshold is robust.

Another relevant point in the process is the non-use of more advanced techniques based on artificial intelligence or machine learning and the motivations behind this choice. Although such techniques were initially considered, the Levenshtein distance algorithm was strategic due to its simplicity, computational efficiency, and scalability. However, it is essential to acknowledge that using artificial intelligence-based models could identify more complex patterns of inconsistency. Nevertheless, the computational cost generated by these techniques is a considerable barrier, especially in massive datasets like the SGP, which manages around 7 million records. Furthermore, implementing these solutions requires advanced technical infrastructure and specialized teams, which are not always available in educational systems with limited budgets.

At the same time, we do not rule out the use of machine learning techniques in the future, combined with traditional methods, such as dynamic adjustment of similarity thresholds, metric learning, name preprocessing, and automated alerts to system operators about potential inconsistencies. Thus, although this study focused on a low computational cost solution, there is considerable room for expanding and improving the developed practices, aiming for greater efficiency in the system and ensuring increasingly reliable data.

Finally, data interoperability proved to be a powerful tool for improving the quality of information within the context of the SGP. Integration with the Federal Revenue database enabled the identification of inconsistencies and error reduction, ensuring greater reliability for public policies such as the Pé-de-Meia Program. Future work can explore expanding this model to other government databases, increasing the system's scope and reliability.

7. Final Remarks

This study consolidated the importance of digital transformation and data interoperability in the context of digital governments, with an emphasis on large-scale educational systems such as the SGP. The adoption of the Levenshtein distance algorithm, combined with a similarity threshold of 80%, proved to be an effective solution for addressing discrepancies in records, ensuring the quality and integrity of processed data. By prioritizing scalable and accessible solutions, this work exemplifies how simple technologies can be adapted to tackle complex operational challenges, contributing to the modernization of the SGP and the implementation of more efficient public policies, such as the Pé-de-Meia program.

Furthermore, the interoperability between the SGP and the Federal Revenue database highlighted the potential of data integration to optimize processes and increase the reliability of governmental systems. This model, although developed for the Brazilian educational context, presents principles that can be adapted to other sectors and countries, especially those facing similar challenges of data heterogeneity and fragmentation.

For future work, it is proposed to expand interoperability with other governmental databases, such as the Cadastro Único and the National Basic Education Assessment System (SAEB). Additionally, adopting hybrid techniques that combine traditional methods with machine learning can open new opportunities to address even more complex contexts, preserving efficiency and scalability as priorities. Thus, this study not only meets a practical demand but also makes a significant contribution to the literature on data interoperability and educational management.

Track 2: Artificial Intelligence Transforming the Public Sector

Track Description

AI diffusion across government levels and domains has continued to grow, including policy development, implementation, execution, monitoring, and enforcement. The emergence and rapid diffusion of AI applications in society have led to a growing consensus on the need for AI governance and the transformation of practices, organizations, and institutions. Next to the opportunities, AI might impact society negatively. In response, there is a growing stock of AI design, implementation, and governance frameworks and tools to support AI developers and AI practitioners in government organizations in ensuring the responsible deployment of AI in transforming public services and policy-making. However, empirical studies of government use of AI technologies are sparse. Hence, the purpose of this track is to investigate how AI is being implemented, adopted, used and governed at different levels of government, how the institutional contexts are shaping AI systems in government, and how to ensure that AI adoption in government remains trustworthy and beneficial to the public at large.

Abstract. The impact of Artificial Intelligence (AI) on emergency policies has been widely examined in digital government literature, focusing primarily on AI's role in policy design and delivery and on its effects on policy outcomes. However, limited attention has been given to how AI directly impacts emergency policies' change, that is, in which ways AI reshapes and steers the policies it mediates. Drawing on Hacker et al. (2015) framework of institutional change, particularly the concepts of drift and conversion, this research provides a novel lens to understand policy change in emergency contexts. Drift occurs when policies remain formally unchanged but fail to adapt to evolving contexts, altering their effects. Conversion refers to the redirection of policies towards new purposes without modifying their formal structure. By applying this framework, the paper investigates AI's dual role in changing emergency policies, both as a source of resistance to formal policy change and a catalyst for policy redirection. The research adopts an explanatory case study of Peru's welfare policies during the COVID-19 pandemic, focusing on the use of the SISFOH AI system to allocate emergency subsidies. Findings demonstrate how AI changes the policies it mediates by drifting formal policy modification and enabling conversion by reshaping policy ends. This paper contributes to the digital government literature by highlighting AI's ambivalent role in emergency policy change and offering fresh insights into the intersection of AI and emergency policies.

Keywords. Artificial Intelligence, emergency policies, policy change, COVID-19 pandemic, drift, conversion.
Research paper, DOI: https://doi.org/10.59490/dgo.2025.949

1. Introduction

Artificial Intelligence (AI) is increasingly recognized as a pivotal tool in shaping public policies, particularly in emergency contexts where time-sensitive, data-driven decisions are crucial (Scholl, 2023). The integration of AI into public administration has transformed how governments respond to emergencies, enabling more efficient resource allocation, enhanced impact assessments, and targeted interventions (Nasseef et al., 2022). In the domain of emergency policies, AI's role has been predominantly examined through its contributions to policy design and delivery, as well as its influence on policy outcomes (Agarwal et al., 2024; Yu et al., 2024). However, a critical dimension remains underexplored: how AI actively reshapes and steers the evolution of the policies it mediates. Very limited knowledge is offered on what happens between the ex-ante policy design and the post-facto assessment of the outcomes: indeed, policies are not fixed, they evolve and mutate over time (Pierson, 2006). Understanding the impact of AI on policy change is crucial because often emergency policies relying on AI evolve, which requires additional policymaking efforts to ensure expected goals are achieved without distortions (Milan et al., 2021). This paper addresses this gap by investigating how AI impacts emergency policy change, advancing our understanding of the intricate ways in which AI drives different forms of policy evolution.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

To unravel how AI impacts emergency policy change, the paper adopts an institutional theory perspective, and it builds on the theoretical framework of institutional hidden change as outlined by Hacker et al. (2015). This framework introduces the concepts of "drift" and "conversion" to explain hidden forms of policy change. This research applies the drift and conversion framework to the context of AI-driven emergency policies, positing that AI can act as both a source of resistance to formal policy change (drift) and as a catalyst for policy redirection (conversion).

To shed light on this phenomenon, this paper addresses the following Research Question: *How does AI act as a source of drift and conversion affecting emergency policy change?*

To empirically explore these dynamics, the paper examines the case of the Peruvian government's AI-based Households Targeting System (*Sistema de Focalización de Hogares*, herein SISFOH), which played a central role in allocating emergency subsidies during the COVID-19 pandemic. Qualitative data from interviews with key policymakers provide evidence to illustrate how AI can simultaneously constrain and enable policy evolution, reflecting the dual processes of drift and conversion.

Building on the findings of the case study, the paper provides two main contributions. First, it extends the theoretical application of institutional change frameworks to the study of AI in governments' emergency policies, offering a nuanced perspective on how AI interacts with those policies. Second, it theorizes the ambivalent nature of AI's impact on policy change, illustrating its capacity to both resist and facilitate change. In doing so, this paper bridges a critical gap in the literature, addressing the underexplored intersection of AI and policy change in emergency contexts. It underscores the importance of understanding AI not merely as a tool for policy implementation but as an active agent that influences the trajectory of policy development.

2. Background

Literature has addressed the impact of Artificial Intelligence (AI) on governments' emergency policies in the context of the COVID-19 pandemic looking at two main issues: the use of AI to design and deliver emergency policies (Hagen et al., 2021; Nasseef et al., 2022; Rodriguez-Hidalgo, 2020), and the effects of AI on the outcomes of the emergency policies (Agarwal et al., 2024; Mhlanga, 2022; Qureshi, 2021). The first stream of research has investigated how AI can be utilized in the public sector to support an enhanced emergency policy provision (Yu et al., 2024). Specifically, there is now increasing evidence about the impact of AI in assisting policymakers by maximising the data available and offering improved impact assessments and forecasts (Agostino et al., 2021; Anshari et al., 2023). The adoption of AI instruments in the early stages of the decision-making process, including policy formulation and design, has enabled the public sector to reach a more informed and data-driven awareness (Moser-Plautz & Schmidthuber, 2023) that could limit the mismatches between the purpose of the policies and the means available in the policymakers' hands, which is crucial in emergency circumstances (Kummitha, 2020).

The second stream of research has mainly focused on the effects of AI on the outcomes of the policies (Agarwal et al., 2024). Contributions to this research effort have shown a more mixed picture. AI adoption in the public sector has often triggered unexpected outcomes. For example, AI tools to streamline service delivery have created misallocations that have unevenly impacted the population which is deeply problematic in countries already affected by social inequalities (Cerna Aragon, 2021). Moreover, AI adoption has been challenged by social groups due to discrimination and distortions (Milan et al., 2021; Naudé & Vinuesa, 2021). To complicate even more the picture, increased attention on the ethical issues related to AI-driven public policies has requested scholars and policymakers to closely scrutinize the effects of AI on the policies it informed (Qureshi, 2021).

The relevance of these two streams of research is undeniable and it is likely to be enhanced as the adoption of AI instruments to address emergencies is increasing at a fast pace (Urueña, 2023). However, in the complex entanglement between AI and emergency policies, the study of how AI impacts policy change has not received adequate attention. The literature has widely addressed how AI can be utilized before the policy is designed (Agarwal et al., 2024; Agostino et al., 2021) and what are the effects of AI after the policy has been implemented (Naudé & Vinuesa, 2021), however, there is a scarcity of works that examine the impact of AI on the change of the policy. Regrettably, literature has overlooked policy change for a long time, focusing more on other aspects such as the design, implementation, and evaluation of policies (Kuziemski & Misuraca, 2020; Lundgren et al., 2020; Moser-Plautz & Schmidthuber, 2023). However, this approach has shown limits because the space between the design and the implementation offers many opportunities for AI to deploy its effects and shape the evolution of the policy. Indeed, scholars reflecting on emergency policy design have called for a more dynamic perspective on the impact of AI on the whole phases of policymaking (Meijer & Webster, 2020). Although valuable, this stream of research mostly focuses on the process as a unit of analysis. Despite its relevance, scarce and limited knowledge exists on the study of how emergency policy evolves and modifies when AI is used to inform it.

To address this gap, the paper aims to explore policy change through a more nuanced understanding of the impact of AI on policies. By unpacking the different ways in which AI affects policy change, the paper accounts for the

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

effects of AI that reshapes and steers the evolution of the policies it mediates. This research aims to connect with the longstanding research stream that has discussed how digital technologies – including AI – entangle emergency policies (Scholl, 2023). Beyond that, the paper aims to add to the limited works on the impact of AI on emergency policy change, adding fresh knowledge and theorization to a crucial phenomenon.

3. Theoretical Framework

To shed light on how AI impacts emergency policy change, the paper relies on the theoretical framework used by Hacker et al. (2015) to explain institutional change. In this section, justifications are provided to explain (a) what the framework is about; (b) why this framework has been selected to investigate the phenomenon; and (c) how to operationalize the key dimensions of the framework in the analysis.

The work by Hacker et al. (2015) is rooted in the discipline of public policies and aims to investigate how policies evolve and change without formal revision (Hacker et al., 2015). Challenging the predominant stream of research of institutional theory that focuses on major changes in a long-term timeframe (March & Olsen, 1983; Powell & DiMaggio, 2012), public policies scholars have advanced the idea of "hidden forms of institutional change" (Hacker et al., 2015, p. 181). Hidden change refers to the modification of the policies that happens without a formal revision of the rules. Hidden change happens through two forms: drift and conversion (Hacker et al., 2015).

The concept of drift is explained as the failure of policymakers to update policies to reflect mutated social circumstances (Hacker et al., 2015). In other words, the change of the policy is resisted despite significant pressures to adapt the policy to a new context. It is worth noting that the concept of drift here is presented slightly differently from the one portrayed in other disciplines that have studied change related to technology, e.g. Information Systems, where drift is referred to as the deviation from planned purposes due to reasons beyond the control of actors (Ciborra & Hanseth, 2000). While the origin is similar – drift occurs when there is a modification of the surrounding context that triggers change – the emphasis on drift as presented by Hacker and colleagues lies on the attempts to maintain the status quo ante by not adapting policies despite the context transformations, which results in altered effects of the policies.

Conversion is a form of change occurring when a policy is redirected towards new ends (Hacker et al., 2015). In a similar fashion to drift, conversion happens without modifying formal aspects of the policy. However, the key difference is that while drift explains how a change in the policy is resisted despite context modifications, conversion accounts for how policy change is enabled by redirecting the policy to different purposes than those originally engineered. In other words, conversion occurs when policies designed and deployed to achieve specific sets of goals are harnessed by actors to execute different tasks within the same formal (legal-institutional) framework (Hacker et al., 2015). Similarities and differences between drift and conversion are presented in Table 1 below.

Tab. 1 – Key characteristics of drift and conversion. Source: authors' elaboration building on Hacker et al. (2015)

	Source of change	Substantial impact on policy	Formal impact on policy	Driving force
Drift	Context discontinuity	Policy's effects altered because of modified circumstances	Left unchanged	Resistance
Conversion	Actors' initiative	Policy's purposes shifted towards different ends	Left unchanged	Redirection

The above-presented framework has been selected for several reasons. First, it enables an investigation of the impact of AI on emergency policy change using a lens that focuses on the policy as the unity of analysis. In this light, the representation of policies as formal institutions (Pierson, 2006) is crucial because it accounts for how policies "set rules for social interactions that are enforced through the exercise of public authority" (Hacker et al., 2015, p. 183). The paper aligns with this conceptualization that enables a more specific investigation at the policy level. Second, it offers a new angle on an emerging phenomenon. The institutionalist perspective has widely been used to investigate the effects of technology on organizational change (Avgerou, 2004; Fountain, 2001; Luna-Reyes & Gil-Garcia, 2011). However, very limited works have utilized institutionalism to understand the impact of AI (Caplan & boyd, 2018; Rudko et al., 2024) and, specifically, the impact of AI on policy change. Third, the theorization advanced by Hacker et al. (2015) provides adequate granularity to unpack how AI influences emergency policy change. The identification of drift and conversion as key forms of change offers analytical tools to shed light on how the policy change happens.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

The framework by Hacker et al. (2015) is a powerful analytical tool to appreciate the impact of AI on policy change. Indeed, the original framework is outlined by the authors to study public policies, that is, to understand which political actors drive drift and conversion in policy change. Utilizing the framework in the field of digital government requires a retuning of the focus, which includes not only the activity of political actors but also the role of digital technology, and in this case AI, as a factor that impacts policy change. Specifically, this research posits that AI triggers both drift and conversion, acting as an ambivalent catalyst for policy change. To validate this assumption, the paper outlines two propositions that are going to be tested in the following sections.

Proposition 1: AI is a source of drift because it reinforces resistance to policy change despite evolving contextual circumstances.

Proposition 2: AI is a source of conversion because it shapes the redirection of the policy to achieve distinct outcomes.

4. Methodology

4.1 Research settings

To shed light on the way by which AI impacts policy change, the research adopts an explanatory case study method which is suitable to illustrate how "conditions came to be" (Yin, 2018, p. 238) in specific settings over which the researchers have no control or influence. Explanatory research requires precise methodological choices. First, a review of the relevant literature that enables a thorough definition of the research question (Yin, 2018). Second, the outline of a theoretical foundation that drives the formulation of initial propositions in advance of the data collection (Yin, 2018). To study the impact of AI on policy change, we focus on the provision of emergency welfare measures by the Peruvian public administration, following the occurrence of the COVID-19 pandemic. This case is particularly suitable for the research because the government decided to rely on the SISFOH AI system that was driving the provision of welfare policies in ordinary time to deliver pandemic-related policies. The study of the impact of AI on Peruvian policies provides critical findings to understand how AI generates drift and conversion that underpin policy change.

4.2 Case study

The Peruvian government's welfare provision builds on a "targeting logic", that is, identifying the citizens in need to correctly provide services, avoiding unnecessary expenditures, and streamlining the delivery of measures such as pensions, subsidies, and loans (Silva Huerta & Stampini, 2018). Specifically, SISFOH's main task was to release a Socio-Economic Classification (SEC) of citizens, clustering users as "not poor", "poor", or "very poor", based on their level of poverty. The AI algorithm relied on a combination of criteria, variables and filters: for instance, possessing a vehicle and/or private health insurance, pre-determined levels of salary, and electricity consumption are the critical factors used to determine citizens' levels of poverty (Cerna Aragon, 2021).

In response to the COVID-19 pandemic, the Peruvian government took immediate action to sustain the citizens in need after the imposition of extraordinary decisions like lockdowns and restrictions on movement and business. Therefore, the government designed and released an emergency welfare policy named "Bono YoMeQuedoEnCasa" (I'm Staying at Home), a one-off subsidy of 380 soles (approximately USD 110) per household to support citizens who had lost their job or saw their activity disrupted due to the lockdown. Eligibility for the subsidy was determined prioritizing households (a) classified as "poor" or "very poor", (b) residing in urban areas, (c) that included other adults and not only minors, and (d) where nobody had a job in the public sector. To correctly target those eligible for the emergency subsidy, the government relied on the SISFOH AI, which was used to elaborate a database of the households.

However, implementation challenges arose: the resulting databases provided by SISFOH AI reflected errors in inclusion and exclusion: with citizens not entitled who nevertheless received the subsidy, and citizens in need who were excluded. In aggregate, misallocations concerned nearly 10% of the policy recipients (Contraloria General de la Republica del Perù, 2020). Acknowledging these shortcomings, the government introduced additional subsidies to expand coverage (e.g., self-employed workers, rural households, families). Peruvian policymakers relentlessly transitioned from the targeting approach utilized in the initial phase to the universal approach of the later stage, addressing gaps in the initial program.

4.3 Data collection and analysis

After an initial phase in which the researchers consulted secondary sources to get a background understanding of the issues at stake, the main data collection focused on interviews with high-level policymakers who played a critical role in the design and delivery of emergency policies. As the focus of this research is to understand how the policy changes, we privileged quality over quantity in the number of interviews: therefore, we limited our sample

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

to pivotal policymakers who took the key decisions in the emergency policymaking process (Hansen et al., 2025). In aggregate, we reached out to six key policymakers: three former ministers of the Minister for Development and Social Inclusion (herein MIDIS) who took key decisions in the design and application of the SISFOH system; one former MIDIS deputy minister, and two senior civil servants who designed and delivered the emergency policy. Each interview lasted between 50 to 80 minutes. Interviews were effectuated in late 2022. Four interviews out of six were conducted in English, and two in Spanish (the latter were transcribed and translated to English before beginning the data analysis).

The collected data from the interviews were subsequentially coded using NVivo software. A combination of inductive and deductive approaches was chosen (Charmaz, 2014). Data were coded data relying on the key concepts of drift and conversion from the theoretical framework to assess whether alignment could be identified. Simultaneously, the coding process remained open to recognizing new codes emerging directly from the data. Researchers eventually discussed the codes and reviewed the outcomes, clearing discrepancies.

5. Findings

The findings from the case study mainly show three elements: (a) the relevance of the AI-based policy in defining the status quo ante; (b) how the AI impacted the drift of the policy; and (c) how the AI impacted the conversion of the policy. In this section, we are going to analyse each of these elements in detail with support of primary data.

5.1 Relevance of the AI policy in the Peruvian welfare

When asked about the provision of welfare in Peru, the policymakers interviewed remarked that, before the outbreak of the pandemic, the SISFOH AI was the backbone of the public services distribution. Over the years, increasing public agencies and ministries utilized SISFOH AI as a key information system to assess the eligibility of citizens for distinct social and welfare measures. A former Minister of the MIDIS points out: *"If people wanted to use welfare, they had to stick with SISFOH. Then, the need to have information was not only of a few sectors but was also shared by many actors within the Peruvian government: at that point, many other programs were aggregated to SISFOH, like SALUD, JUNTOS, PENSION65, CONTIGO"* (Interviewee-1). SISFOH AI centralized the information collection, processing, and management within the Peruvian welfare. As such, it established a standardized way to provide welfare services because it engrained the technological characteristics of the AI into the targeting logic of the Peruvian approach to welfare. In other words, the AI had been designed to fulfil a specific task – correctly target those eligible for welfare measures – and it became the standard for distributing welfare measures. Another former Minister explains the centrality of the SISFOH AI with respect not only to the whole welfare provision, but to the definition of the policy itself: *"The creation of SISFOH has provided to the social policy of Peru an instrument that it already had, but that was not an instrument within a policy"* (I-6). In other words, the AI became constitutive of the policy. The AI algorithms engrained into SISFOH provided the public administration with the information without which it would have been impossible to deliver services.

5.2 Challenges of the AI policy in the pandemic context

The outbreak of the pandemic was the contextual event that modified the status quo ante. The immediate response of Peruvian policymakers to the deteriorating living conditions of the citizens was to deliver a monetary subsidy. However, the external context altered the effects of the Peruvian welfare policy based on SISFOH AI. Before the pandemic, the AI-driven policy achieved targeting purposes: those clustered as "poor" and "very poor" received welfare measures, while those not in need didn't. After the pandemic, the effects of the policy generated further exclusion as many people classified by the AI as "not poor" found themselves left out of the database of eligible citizens despite being severely impacted by the pandemic. This aspect is emphasized by a former deputy Minister: *"We only can target people who are poor or extremely poor, but that was before the pandemic"* (I-4). This happened without any formal modification of the policy based on AI: what changed was the social environment. However, vis-à-vis these modified circumstances, the Peruvian policymakers resisted changing the policy, which would have required significant resources given the centrality of SISFOH and the AI engrained into it. Hence, the AI-calculated categories of "very poor", "poor", and "not poor" were applied in the emergency context in the same manner as they would have been during ordinary times. Resistances to change the policy emerged among civil servants and actors tasked to utilize the AI to deliver the first monetary subsidy, as noted by a senior civil servant: *"People* [in the Peruvian public sector] *were used to SISFOH, they had knowledge and expertise"* (I-5). At the time of the pandemic, the Peruvian public administration had relied on the SISFOH AI for several years with considerable success. However, in a situation of a modified environment, the targeting effects of the policy, embodied in the functioning of the AI, generated misallocations in the recipients of the subsidy, exposing the whole policy to *"challenges related to coverage and leakage"* (I-3). Eventually, the government realized that the attempts to leave the welfare policy formally unchanged could expose the emergency measures to significant flaws and weaknesses.

5.3 Adopting the AI policy

The misallocations of the first monetary subsidy urged Peruvian policymakers to pursue an adaptation of the

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

SISFOH AI policy to achieve different ends. The modification of the formal aspects of the policy was excluded as it would have required dismantling not only the policy architecture but also the technological infrastructure of the AI engrained at the core of SISFOH. A former Minister emphasizes this point, reinforcing the boundary conditions within which Peruvian policymakers had to operate: "*Without SISFOH, we would not have been able to design the emergency policy at all. SISFOH did impact, it has radically changed the social policy in Peru"* (I-6). Hence, Peruvian policymakers began efforts to redirect the purpose of the policy leveraging on the potentiality of the SISFOH. The strategy of Peruvian policymakers focused on utilizing the data produced by SISFOH AI with a distinct purpose. While in ordinary time the database of citizens eligible for a specific welfare service was the landing point of SISFOH, in emergency time it became the basis for further subsidies provided by other ministries and agencies building on the information provided by SISFOH AI. The first monetary subsidy was designed and delivered to citizens in less than two weeks: however, due to the prolonged restrictions, several other subsidies were provided to other categories and social groups. Further measures were released to expand the number of people eligible beyond the "poor" and "very poor" citizens classified by SISFOH AI, as explained by a former deputy Minister who accounts for the many queries received about SISFOH data*: "People who lost their jobs, artists, informal workers… All these categories needed Bonos [subsidies], but they weren't poor! We also needed to reach people who weren't poor, but not all of them. So, we used SISFOH data to identify the non-poor"* (I-4). Therefore, building on AI classifications, the Peruvian public administration began to provide subsidies to those who were initially excluded from the recipients of the first monetary measure. This ultimately led to a situation in which the SISFOH AI, designed to increase efficiency and effectiveness in targeting, was the instrument that enabled the Peruvian government to effectuate reverse targeting. Policymakers pursued reverse targeting until the recipients of the subsidies reached almost universal coverage. This is confirmed by a former Minister who explains how the provision of a subsequent subsidy to informal workers occurred: "*They had the national ID registry; they took out from that registry all the people that remained with a formal job. And that's it: everybody else should receive a Bono, that was the reverse targeting"* (I-2).

6. Discussion

The purpose of the research is to understand the impact of AI on emergency policy change. To achieve this goal, findings from the case study of the Peruvian government's emergency measures are discussed through the analytical lens of drift and conversion framework as portrayed by Hacker et al. (2015) to validate Propositions 1 and 2 above presented.

6.1 AI as a source of drift

Proposition 1 upholds that AI can be a source of drift underpinning resistance to policy change when the contextual circumstances modify. Key characteristics of drift, as summarized in Table 1, are (a) context discontinuity; (b) alteration of policy's effects due to evolved context; (c) formal policy unchanged; and (d) resistance as a driving force.

Concerning context discontinuity, findings from the case study indicate that the outbreak of the COVID-19 pandemic represents the transformation of the social circumstances altering the status quo ante. Specifically, the context discontinuity observed in the case takes the shape of a major disruption that overturns the social order. An event like the pandemic – without the reasonable control of any of the actors – embodies a more than sufficient modification of the context to trigger the policy change in the form of drift.

The context discontinuity impacts the effects of the policy: the AI was originally designed to target citizens eligible for welfare services and to exclude those not eligible. The engrained technology at the core of the policy – SISFOH's AI – produced altered effects in the pandemic context generating additional leakages and distortions in the subsidy administration. The SISFOH AI had been designed to provide only a static understanding of poverty, based on data that did not capture the modified poverty circumstances.

In these settings, Peruvian policymakers decided to avoid the formal modification of the policy, which would have requested an alteration of the technological infrastructure of the AI at the core of SISFOH. The formal scaffolding of the Peruvian welfare system relying on SISFOH remained in place without modifications. Two motivations can explain this choice. First, civil servants tasked with administering the policy were accustomed to the use of SISFOH, and an abrupt discontinuation such as a policy formal change would have impacted the chances of the monetary subsidy being delivered effectively. However, there is a second element that deserves to be unravelled: the specific role of AI in the formal constitution (Pierson, 2006) of the policy. The centrality of the AI algorithm within SISFOH, and the pervasiveness of SISFOH within the Peruvian welfare system, generated an additional source of resistance towards a formal modification of the policy.

Drift elucidates a substantial change in the effects of the policy without formal modifications, as a consequence of an evolved context (Hacker et al., 2015). In this respect, policy change is supported not only by actors' behaviour but also, and more significantly, by the impact of AI. When the context shifts the effects of the policy, the AI shapes

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

the policy change by creating resistance to any formal modification, drifting the policy towards unexplored territory. In other words, the policy changes not only because the context has altered its effects, but also because the AI has prevented any formal modifications to the policy itself. Accordingly, proposition 1 can be considered validated.

6.2 AI as a source of conversion

Proposition 2 upholds that AI can be a source of conversion, shaping the redirection of the policy to achieve different outcomes. Key characteristics of conversion, as summarized in Table 1, are (a) actors' initiative; (b) adaptation of policy's purposes towards different ends; (c) formal policy unchanged; (d) redirection as driving force.

Actors' initiatives refer to the proactive decisions taken by relevant policymakers to modify the circumstances (Hacker et al., 2015). In contrast to drift, the source that triggers policy change is not the context – although the context is not irrelevant – but rather the behaviours of policymakers. Findings from the case study show that Peruvian policymakers reacted to the misallocations and disruptions generated by the delivery of the first monetary subsidy. Policymakers acted under the pressure of providing immediate relief to those impacted by the pandemic and excluded by the AI classification of "poor" and "very poor".

Similarly to the drift form of change, conversion occurs when the actors leave unchanged the formal constitution of the policy. The modification of the SISFOH infrastructure at the core of the welfare provision encounters the same challenges characterizing drift: it is impossible to disentangle the AI engrained in SISFOH from the policy architecture, which is diffused across several branches of the government. Further, despite its limitation, the AI had released enough information to deliver an initial subsidy provision, even if incomplete. The design and delivery of the first monetary subsidy constituted a benchmark for policymakers who aimed to rely on AI to provide further measures. Indeed, the SISFOH AI turns out to be a necessary condition for implementing other policies, not only because the rigidity of the AI-driven policy limits the options available to policymakers, but also because without the use of AI, delivering further policies becomes impossible.

This specific nature of the AI leaves the policymakers with the only option to adapt to the purposes of the policy without changing its formal constitution. Furthermore, the actors engage in a redirection of the policy towards completely different purposes than those that drove its design: from targeting, aimed to exclude those not eligible, to reverse targeting, to include those not yet covered by any measure. Concerning the adaptation of the policy, the role of AI deserves further discussion. The findings of the case study account for the policymakers' decisions and acts, however, the impact of AI in constraining the options available cannot be neglected. The AI, setting boundaries between what is possible to achieve and what is not, has a critical role in substantially adapting the policy towards new and distinct purposes. It is the SISFOH AI installed base that orientates the redirection of the policy.

Conversion happens because policymakers aim to adapt the ends of the policies vis-à-vis the unfeasibility of formally changing the policy (Hacker et al., 2015). In this context, policy change occurs because the redirection of the policy is steered by an entanglement made of policymakers' actions and AI-defined boundaries of the redirection. Accordingly, proposition 2 can be considered validated.

6.3 The ambivalence of AI in drifting and converting policies

The validation of the propositions outlined building on the framework by Hacker et al. (2015) accounts for the role of AI impacting policy change: when AI is engrained at the core of the policy, it acts as a source for drift and conversion. However, the analysis emphasizes an additional element: AI possesses the capacity to drive both drift and conversion forms of policy change.

On the one hand, AI drifts the policy change by creating resistance to formal policy modifications which overshadows the need to adjust the mutated effects of the policy. On the other hand, AI enables a substantial redirection of the policy ends that enable policymakers to achieve significant outcomes without formally altering the policy. The embedding of the AI within the policy and the diffusion of the policy within the welfare system confers the AI a critical relevance in the whole public administration scaffolding, up to the point that a formal modification of the AI-driven policy encounters several challenges. However, the same factors that make the formal modifications unfeasible – the centrality of AI engrained in the policy and the centrality of the policy within the system – drive the adaptation of the policy towards other ends which ultimately serves the interests of the policymakers. In other words, the AI possesses an ambivalent capacity to impact policy change because it is both a source of drift and conversion.

7. Conclusions

This research has explored the transformative role of Artificial Intelligence (AI) in emergency policy change,

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

focusing on its dual capacity to resist and enable policy change through the theoretical lens of drift and conversion (Hacker et al., 2015). By analysing the case of Peru's SISFOH AI system during the COVID-19 pandemic, the research has illustrated how AI reshapes policies in ways that extend beyond their original design, highlighting its ambivalent role in both stabilising and adapting policy frameworks.

The findings demonstrate that AI systems when embedded into policy processes, act as powerful institutional actors (Avgerou, 2004; Rudko et al., 2024). On one hand, the SISFOH system triggered drift, resisting formal policy changes even as the pandemic dramatically altered the socio-economic context. This resistance stemmed not only from the public administrators' inertia but also from the structural centrality of the AI itself, which constrained policymakers' capacity for formal reform. On the other hand, the same system enabled significant policy redirection through conversion, as policymakers leveraged SISFOH's capabilities to expand welfare coverage and address emergent challenges. By facilitating reverse targeting and reorienting policy goals, AI proved instrumental in adapting to the demands of a rapidly evolving crisis.

These findings contribute to the digital government literature in several ways. First, they underscore the importance of studying AI not merely as a technical tool but as a dynamic force that interacts with institutional structures to shape policy change (Agostino et al., 2021; Luna-Reyes & Gil-Garcia, 2011). Second, they offer empirical insights into the complexities of AI-driven policy change in emergency contexts, where resource constraints and socio-economic inequalities amplify the stakes of emergency response (Firmino & Evangelista, 2023; Meijer & Webster, 2020).

However, this research also raises important questions about the governance of AI in public administration. The dual capacity of AI to resist and facilitate change suggests that its integration into policy processes must be carefully managed to balance stability and adaptability (Valle-Cruz & Sandoval-Almazán, 2024). This implies the need for a more robust, modular approach to AI design, that facilitates reprogramming and re-tailoring to achieve desirable outcomes. Moreover, policymakers must consider the ethical and operational implications of AI-driven systems, particularly in contexts where technological limitations may exacerbate social inequities (Milan et al., 2021). Furthermore, the findings point to the need for ongoing scrutiny of how AI shapes policy outcomes over time, calling for future research into its long-term institutional effects (Cordella & Gualdi, 2024).

In conclusion, this research highlights the ambivalent role of AI as both a source of drift and conversion forms of policy change. As governments increasingly turn to AI to address complex challenges (Scholl, 2023), it is crucial to recognise and navigate its dual nature, ensuring that the integration of AI into policymaking serves not only to optimise outcomes but also to uphold principles of equity and inclusivity. By advancing the understanding of how AI drives hidden forms of policy change, this research contributes to a deeper appreciation of the transformative potential of digital technologies.

Abstract. Recently, governments and organizations have expanded their interest and efforts toward acquiring Artificial Intelligence-powered systems to support the delivery of public services. However, there is insufficient information in the literature to help us understand how different types of public services are supported by AI, particularly regarding aspects such as collaboration support and the innovation achieved within organizations. To address these literature gaps, we conducted a rapid review to identify types of AI applications, problem solved, government functions supported, their impacts on innovation in public organizations, and the collaborative arrangements they have fostered among various stakeholders. Furthermore, in this same scope, we also designed a taxonomy as an analytical framework to answer the literature review questions. The review found that AI in the public sector is mainly used for prediction, data visualization, predictive analysis, and automating repetitive processes, particularly in economic affairs, health, and public order. Governments develop AI solutions primarily for administrative and repetitive tasks. In this sense, there is potential growth for new AI adoption forms and public management innovations, benefiting public service delivery and society. These contributions aim to help researchers, public managers, and tech companies better understand and analyze the complex domain of AI in public services, enabling them to develop and responsibly implement new AI solutions in the future.

Keywords. Artificial Intelligence, Public Services, Taxonomy, Digital Government, Human-AI interaction, Collaboration
Research paper, DOI: https://doi.org/10.59490/dgo.2025.950

1. Introduction

Recently, governments and organizations responsible for providing public services have increased their interest in acquiring Artificial Intelligence (AI) technologies to support public services (Sousa et al., 2019). Potential benefits are pointed out in several sectors related to the public sector, such as public health, climate change, disaster prevention and response, and government-citizen interaction, among others (Luusua et al.,2023), (Valle-Cruz et al., 2019). Such AI-powered services can be incorporated into the urban environment (Luusua et al.,2023), be made available in digital services such as citizen inquiries and information (Mehr, 2017), or be directly linked to the bureaucratic functioning of public entities or directly related to the decision-making process. of decision-making by public managers (Kuziemski and Misuraca, 2020).

In this context, many researchers have been investigating the topic of AI in the public sector. For example, Wirtz et al. (2019) present a conceptual approach to and analysis of AI applications and challenges. They identify ten AI application areas and discuss their value creation and functioning, as well as specific public use cases. Similarly, Sousa et al. (2019) discuss insights from AI projects in government and present a classification framework for AI applications in the public sector. Their framework aims to facilitate the deployment of AI in the public sector by providing a lens to different deployment-related questions.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Nevertheless, Desouza et al. (2020) and Zuiderwijk et al (2021) highlight governments and public organizations' increasing interest in and adoption of AI systems. More specifically, the first offers a systematic review of existing literature on the implications of AI in public governance, and the latter reviews a sample of 250 cases across the European Union and finds that AI is primarily used to support improving public service delivery, followed by enhancing internal management. They both also discuss the complexities and risks of implementing those systems. Also, through a systematic review, Valle-Cruz et al. (2019) collected 78 publications and applied a public policy framework to identify future areas of implementation. In addition to these, Straub et al. (2023) also conducted a literature review and developed a typology addressing concepts such as operational fitness, epistemic alignment, and normative divergence.

Despite the advancements in the field and the efforts from academia to understand this phenomenon, some aspects related to the impact of AI adoption on innovation and collaboration in the public sector remain open. Besides, it is noted that there is a need to create more robust classification structures that allow organizing knowledge about AI applications in public services.

In this sense, this work has two complementary objectives: (i) to conduct a literature review aimed at mapping how AI applications have been used, their impacts on innovation in the public sector, and the collaborative arrangements they have fostered among various stakeholders; (ii) to design a taxonomy that allows for the classification of AI applications in the public sector, including aspects related to innovation and collaboration. Furthermore, we validated the taxonomy as an analytical framework to answer the literature review questions. Finally, we expect that these contributions can support researchers, public managers, and tech companies in understanding and analyzing the complex domain of AI in public services to create and responsibly adopt new AI solutions.

2. Theoretical background

2.1 Public Services and Government Functions Definitions

As presented by Denhardt and Denhardt (2000), although the execution of services conducted by complex and organized governments is ancient, public administration as a field of practice and reflection dates back to the late 19th century. The traditional public management practice, primarily centered on hierarchy and efficiency, and the perception of the public interest has evolved. The two main contemporary streams of thought regarding models of public service revolve around the clash of market-based models focusing on efficiency versus models based on democratic values and the effectiveness of government work.

The concept of Public Services in this work is associated with the idea of Services of General Interest (SGIs), which are services provided by government and private organizations operating under some form of state regulation or public contract. The term SGI was coined within the context of the European Union and reasonably avoids the semantic ambiguities that the term' public services' may carry due to the philosophical perspective one holds on the subject. The term primarily refers to tasks and functions assumed as essential services for the quality of life of citizens, their well-being, and the functioning of society (Bjørnsen et al., 2015).

Given the differing perceptions of what constitutes public services, this work will utilize the Classification of the Functions of Government (COFOG) developed by the Organisation for Economic Cooperation and Development (OECD), as presented in Table 1, to reference the context or function of public services that AI tools support. COFOG consists of 10 first-level groups of government functions divided into 69 second-level subgroups.

2.2 Types of problems and AI applications in Public Services

Wirtz et al. (2019) discussed types of AI applications, describing various categories of AI-based systems, their functional propositions, and public sector use cases. The systems addressed in this research are AI-Based Knowledge Management (KM) Software, AI Process Automation Systems, Virtual Agents, Predictive Analytics & Data Visualization, Identity Analytics, Cognitive Robotics & Autonomous Systems, Recommendation Systems, Intelligent Digital Assistants (IDA), Speech Analytics, Cognitive Security Analytics & Threat Intelligence. Wirtz et al. applied an AI value creation and functional proposition within each of them, as well as its use cases in the public sector.

• AI-Based Knowledge Management Software: Generation and systematization of knowledge – gathering, sorting, transforming, recording, and sharing knowledge. Distribution, sharing, and analysis of knowledge with neural networks, with its usage in the public sector on clinical documentation powered by AI.

• AI Process Automation Systems: Automation of standard tasks; performing formal logical tasks with unpredictable conditions, complex human action processes, and robotic process automation, with its usage in the public sector on Faster and higher quality request processing for immigration applications, automated image diagnoses, human-computer interaction for repetitive tasks.

• Virtual Agents: Computer-based systems that interact with users through speech analysis, computer vision, and written data input. For example, it is used in the public sector in virtual nursing assistance and chatbots to help refugees seeking asylum.

• Predictive Analysis & Data Visualization: Analytics based on quantitative and statistical data analysis. Processing of Big data for reporting, prescriptive and predictive analysis. Its usage in the public sector is in control, performance, and monitoring of public areas for police departments to determine terror threats and crime hotspots for preventive action.

• Identity Analytics: Software combined with big data, advanced analytics and identity access management to control access to IT systems with deep and machine learning. Facial recognition software is used in the public sector to verify and identify criminals in public spaces.

• Cognitive Robotics & Autonomous Systems: Higher-level cognitive function systems involving knowledge representation that can learn and respond. Its usage in the public sector in electric-powered autonomous vehicles for public transportation.

• Recommendation Systems: An information filtering system. Its usage in the public sector in E-service for government offices to provide personalized information for employees.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

• Intelligent Digital Assistants (IDA): Software based on speech analytics, providing an intuitive interface between user and system. Its public sector usage connects federal programs to IDAs to make public service information available to customers.

• Speech Analytics: Software for intelligent recognition and processing of language, translation from spoken to written language, or from one to another natural language. Its usage in the public sector in Real-time universal translation to translate speech and text in face-to-face communications in public service settings.

• Cognitive Security Analytics & Threat Intelligence: Additional application for cognitive technologies to analyze security information through natural language processing and machine learning. Its usage in the public sector in Applications like Watson for cybersecurity to support human security analysis.

Mehr et al. (2017) also acknowledge the potential benefits of AI in the public sector, such as improving government efficiency, enhancing citizen engagement, and modernizing service delivery. However, they also highlight several significant concerns, difficulties, and obstacles that must be addressed.

• Resource Allocation: Require administrative support to speed up task completion. Its Inquire response times are long due to insufficient support.

• Large Datasets: The dataset is too extensive for employees to work efficiently. Internal and external can be combined to enhance outputs and insights.

• Predictable Scenario: The situation is predictable based on historical data. Prediction will help with time-sensitive responses.

• Procedural: The task is repetitive by its nature. Its inputs and outputs have a binary answer.

• Diverse Data: It includes visual/spatial and auditory/linguistic information. Quantitative and qualitative data need to be summarized regularly.

2.3 A typology of Public Service innovation

Processing of Big data for reporting, prescriptive and predictive analysis. Its usage in the public sector is in control, performance, and monitoring of public areas for police departments to determine terror threats and crime hotspots for preventive action.

Chen et al. (2020) introduced a comprehensive typology to elucidate and classify innovative endeavors within public service organizations. This typology is characterized by two pivotal dimensions: 'innovation focus,' which encompasses three distinct public value creation processes, namely strategy, capacity, and operations, and 'innovation locus,' which discerns between internal and external innovation sources. The confluence of these dimensions yields an intricate taxonomy comprising six distinct categories of innovation, each delineated as follows:

• Mission Innovation: This classification introduces a novel worldview, mission, or overarching purpose that transcends the entirety of the organization, encapsulating a holistic transformation in its fundamental ethos.

• Policy Innovation: Within this purview, the emphasis lies in introducing new paradigms of benefits and obligations to stakeholders, aiming to address and alleviate societal issues. Policy innovation extends beyond traditional frameworks to encompass a broader societal perspective.

• Management Innovation: This facet pertains to the infusion of innovative management practices, processes, structures, or techniques, with the express objective of enhancing the organization's capacity for advancement and effectiveness.

• Partner Innovation: This category is characterized by establishing innovative partnerships to augment the organization's prowess in achieving its strategic goals and objectives. Partner innovation underscores the value of external collaborations in catalyzing organizational progress.

• Service Innovation: Under this rubric, the focus is on the inception and provision of innovative services meticulously designed to align with and fulfill the organization's overarching goals and mission.

• Citizen Innovation: This genre encompasses the creation of novel platforms and avenues geared explicitly towards facilitating citizen engagement and collaboration in pursuing organizational objectives. Citizen innovation heralds a shift towards inclusive governance models.

This typology will help identify the focus and locus of AI solutions and their contribution to innovation in public services.

2.4 Collaboration between Agents and Human-Machine Networks

Artificial intelligence can significantly enhance collaboration among diverse agents, thus facilitating innovation in public services. Hartley et al. (2013) explain that theories of collaborative innovation in the public sector emphasize the importance of network governance and inter-organizational learning. These theories highlight how

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

collaborative networks can solve complex problems and drive significant changes through interaction. Another widely recognized theory addressing how innovation is a product of interaction among multiple agents is presented by Leydesdorff & Etzkowitz (1998). Through the concept of the triple helix of innovation and entrepreneurship, the authors argue that the key agents responsible for innovation are universities, industry, and government through their interactions. Therefore, this collaboration is essential for knowledge-based economic growth, as it allows the public sector to benefit from the knowledge and expertise of academia and industry. The innovations resulting from this process can potentially transform the delivery of public services, making them more efficient, accessible, and tailored to societal needs.

Furthermore, Linders (2012) highlights citizens as another important agent by emphasizing the growing significance of "citizen co-production" in public service provision. Instead of being passive clients, citizens play an active role as partners in service delivery. This approach helps mitigate budgetary challenges in the public sector and leverages new technological tools that enable mass collaboration. As technology advances, the relationship between government and citizens evolves, with "citizen co-production" becoming more relevant and feasible. This phenomenon means that citizens can actively contribute to innovation in the delivery of public services by participating in policy definition and service improvement.

Kattel et al. (2020) focus on the increasing adoption of technology and automation in the public sector, presenting intelligent machines as yet another agent. As intelligent machines play a greater role in delivering public services, collaboration includes machine-machine and human-machine interactions. These interactions are shaping the space for innovation as new technologies and approaches are developed to enhance the efficiency and quality of public services. Automation and artificial intelligence can play a fundamental role in process optimization, data collection and analysis, and personalization of services to meet individual citizens' needs. Furthermore, Tsvetkova et al. (2017) demonstrated that we can represent the collaboration between human agents and intelligent machines through graphical schemes illustrating human-machine networks and their fundamental interactions. In this research context, hybrid arrangements produce synergistic effects in the provision of public services.

3. Methodology

In broad terms, the research design developed to conduct this study integrates, in a complementary manner, the methodological procedures of the Rapid Review method (Tricco et al., 2015) and a method for developing taxonomies in the Information Systems (Nickerson et al., 2013). A Rapid Review is a simplified approach to Systematic Review, where some steps, such as information search and synthesis, can be omitted (Tricco et al., 2015). On the other hand, Nickerson et al. (2013) proposed a method for developing taxonomies that incorporates the Design Science Research (DSR) (Iivari, 2007) approach to generate new knowledge about AI applications in government while designing the artifact, in this case, the taxonomy.

Figure 1 illustrates the methodological procedures carried out in parallel for the rapid review and taxonomy development. After defining the research questions, conducting the search process, and selecting the studies, the extracted data was utilized to develop the taxonomy. This section provides an overview of the review process as well as the systematic approach to creating a comprehensive taxonomy. It details each phase, from establishing the initial meta-characteristics and ending conditions to the iterative refinement cycles, transitioning between conceptual-to-empirical and empirical-to-conceptual stages.

In the first iteration, following a Conceptual-Deductive approach, 60 AI use cases from the selected publications in the review are examined based on the conceptualized characteristics and dimensions. Subsequently, during the second iteration, employing an empirical-inductive approach, all the 103 AI use cases in the selected publications in the review are utilized to identify common characteristics and perform object groupings. After grouping the characteristics into dimensions, we refined the taxonomy. Once finalized, we validated the taxonomy using an analytical framework for data analysis and synthesis of the 103 AI use cases described in the publications.

3.1 Research Questions and Search Process

The planning of this review enables the identification of objectives and the construction of a protocol that presents the research methodology used. Table 2 shows three research questions (RQs) developed to characterize how AI applications have been used, their impacts on innovation in the public sector, and the collaborative arrangements they have fostered among various stakeholders.

Tab. 2 - Research Questions.

ID	Research Question
RQ1	What are the types of AI solutions developed to support public services? And what problems do they solve?
RQ2	Which government functions are using artificial intelligence? And what is the extent of these government functions covered by AI?
RQ3	In what ways do AI solutions support collaboration in the public sector? And, what types of innovation are achieved by implementing AI in public service organizations?

We formulated a search string to answer the research questions by combining terms related to the topic. Tab. 3 shows the search terms. We tested several string combinations of the terms to assess the potential of the returned results. The searches were conducted in the Scopus database for dates after 2018.

Tab. 3 - Search String for Scopus database.

SUBJAREA (comp) TITLE-ABS-KEY (“Artificial Intelligence” OR “Machine Learning” OR “AI”) AND TITLE-ABS-KEY (“public services” OR “public sector” OR “government” OR “city”) AND TITLE-ABS-KEY (“collaborat*” OR “cooperat*”) AND PUBYEAR > 2018

We also formulated another string to collect public reports directly in the Google search engine, as shown in 4. It was necessary because many AI solutions adopted by the public sector are described only in the gray literature.

Tab. 4 - Search String for Google search.

(“Artificial Intelligence” OR “AI” OR “machine learning”) AND (“public services” OR ‘government“ OR “public sector” OR “city”) AND (“collaborate” OR “cooperate”)

3.2 Selection of Studies and Quality Assessment

Table 5 presents the exclusion criteria applied across the search engines throughout the search process. In the Scopus database, the first step involved using the search strings, which returned 658 publications. Then, duplicate publications were excluded, and all selected publications had their titles and abstracts analyzed according to the exclusion criteria, resulting in 156 publications. In the full reading step, we applied the exclusion criteria again and selected 54 publications, each with one AI use case. In Google, the first step involved using the search strings that yielded 33.800.000 results. Then, we went through the first 120 results on the list, evaluating titles and abstracts according to the exclusion criteria. This process resulted in 8 reports with a collection of AI use cases in the public sector. In the full reading step, we again applied the exclusion criteria and selected six reports with 49 AI use cases.

Tab. 5 - Exclusion Criteria.

Criterion	Scopus	Google
The study does NOT answer at least one research question from the RQs	✓	✓
The study does NOT present at least one developed application	✓	✓
The study is a literature review	✓	✓
The study is NOT a report with a collection of AI cases in the public sector		✓

3.3 Meta-characteristic and Ending Conditions

We started by defining a clear meta-characteristic as the base for all classifications. This meta-characteristic ensures that every category logically follows from it, avoiding arbitrary groupings and addressing the needs of scholars, practitioners, and public managers. These users are interested in high-level features that allow them to understand AI's various concepts and applications in public services and how the agents involved collaborate or do not collaborate with these systems. In this sense, these users are not interested in technical aspects of AIs, such as the algorithms used, the model training technique, or the strategies applied for data processing. By anchoring our taxonomy in this high-level meta-characteristic, we ensure each category is relevant and aligned to clarify AI’s essential properties and practical uses in the public sector. This method provides the taxonomy remains coherent

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

and purposeful throughout its development.

Our taxonomy development process follows objective and subjective ending conditions as Nickerson et al. (2013) outlined. The objective conditions are met when the taxonomy is mutually exclusive and collectively exhaustive, meaning each element of AI in public services fits into one unique category without overlap, and all possible elements are covered. The subjective conditions require the taxonomy to be concise, robust, comprehensive, extensible, and explanatory. These conditions imply that the taxonomy should have a manageable number of well-differentiated categories, cover all relevant aspects of AI in public services, allow for future additions, and provide clear, valuable explanations. The development process concludes when these conditions are fully satisfied, ensuring the taxonomy is valid and useful for its intended users.

3.4 First Iteration: Conceptual-to-Empirical

In this iteration, we decided to use a conceptual-to-empirical approach because we already had a theoretical background that provided relevant conceptualizations for this study. From this background, we conceptualized the following dimensions: AI application (Wirtz et al., 2019), Problem-solving (Mehr, 2017), Innovation (Chen et al., 2020), and Government Function (COFOG) (OECD,2023).

Then, we randomly selected 60 of the 103 use cases collected in the literature review and examined them according to the conceptualized characteristics. We noticed that almost all the characteristics identified in the four dimensions corresponded in at least one of the observed cases. The only exception was the Government Function dimension, which had several unmatched characteristics across use cases. Despite this, we still decided to maintain these characteristics because, even if there are no AI applications for certain government functions, soon, this could be different.

Although we inserted four dimensions in this iteration, making it concise, extendable, and explanatory, we realized it could become more robust if we included one more dimension related to supporting collaboration. Because of this, we decided to carry out a second iteration.

3.5 Second Iteration: Empirical-to-Conceptual

In this iteration, we used an empirical-to-conceptual approach to include a new dimension related to collaboration support and discover its characteristics. To do this, we selected all 103 cases from the literature review so that common characteristics could be analyzed and identified.

However, before starting this analysis, defining the types of agents and their relevant interactions was necessary to characterize collaboration. To do this, we were inspired by the work used by Tsvetkova et al. (2017) and used a Human-Machine Networks approach to conduct this research stage. More specifically, we define a pattern language (Van Welie and Van der Veer, 2003) based on an arrangement of agents and interactions, as presented in Fig. **2**.

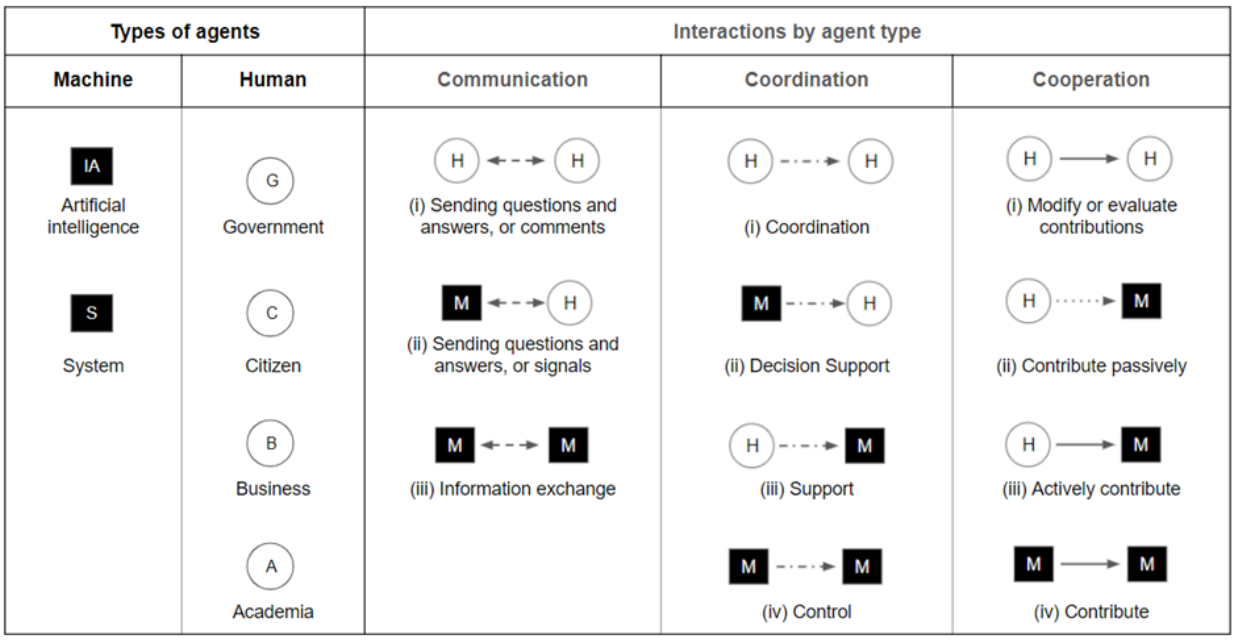

Fig. 2 - Pattern Language of Agents and Interaction in AI in the Public Sector.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

In this arrangement, first, we define the types of agents, which can be machines or humans. The machines were identified as Systems or Artificial Intelligence. System refers to public or private systems that already exist and are in use, which can be traditional information systems or systems that include physical devices such as sensors, actuators, and signals (such as traffic systems and their traffic lights, for example). Artificial Intelligence refers to the AIs presented in the respective selected studies and is a new element within the specific government context in which it is applied. As for human agents, we identified from the theoretical background that Government, Citizens, Business (this term includes industry), and Academia are the main interested parties capable of interacting and collaborating.

Next, we define the types of interactions related to communication, coordination, and cooperation (Fuks et al., 2008). Communication involves exchanging questions, answers, comments, or signals between humans, between humans and machines, and between machines themselves. Coordination occurs when humans organize and manage others, machines support human decision-making, organizations or individuals maintain system functionality through resources and technical upkeep, and machines have command and control relationships with others. Cooperation involves humans modifying or evaluating the contributions of others, passive contributions from humans to machines usually collected automatically, active and voluntary contributions between humans and machines, and machines building upon the contributions of other machines.

We analyzed the 103 use cases identified in the literature from the constructed pattern language. The HMN arrangements represent how they incorporated AI in that government context. Therefore, it was possible to identify common characteristics and group objects according to the agents involved. Fig. **3** presents the primary arrangements already grouped according to the agents involved, which are the characteristics of this new dimension called collaboration support.

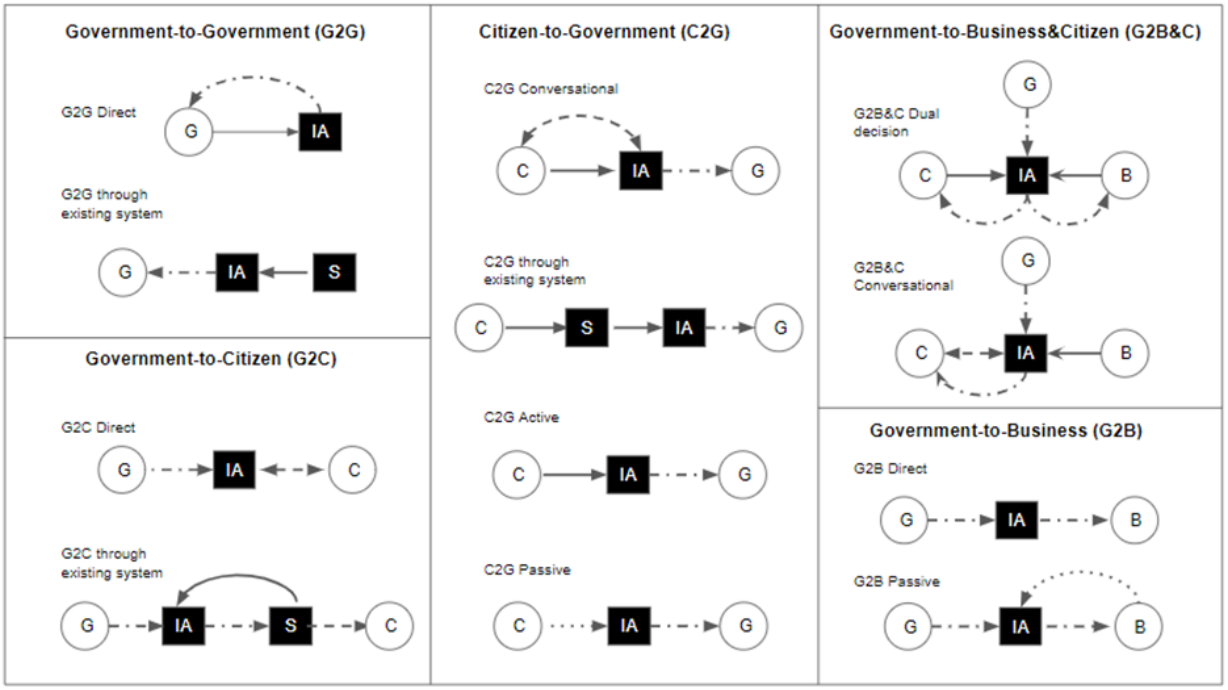

Fig. 3 - Collaboration Support grouped by the Agents involved.

Below, we summarize these main characteristics and sub-characteristics found and described in Fig. **3**:

Government-to-Government (G2G): The government uses AI to solve its own problem. It could be an internal approach for a particular agency or an inter-agency solution.

- Direct G2G: The government actively contributes to AI, providing the necessary data, and AI supports some decision-making directly.

- G2G through the existing system: There is another existing system, private or from the public sector itself, that provides data for the AI and supports some government decision-making.

Government-to-Citizen (G2C): The Government provides an AI capable of supporting citizens in some task type.

- G2C through the existing system: The government supports an AI that receives active contributions from another system and simultaneously controls it, with this system being responsible for sending signals to

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

citizens.

- Direct G2C: The government supports an AI that exchanges questions and answers or sends signals to citizens.

Citizen to Government (C2G): The government supports an AI that directly or indirectly interacts with citizens, obtains information, and supports government decision-making.

- Conversational C2G: Citizens advancing AI while exchanging questions and answers. The data obtained in this process supports government decisions.

- C2G through existing system: Citizens active with an existing system, who in turn actively contribute AI to support government decisions.

- Active C2G: Citizens advanced with AI, and the data obtained in this process supports government decisions.

- Passive C2G: Citizens invest passively with AI, and the data obtained from this process supports government decisions.

Government-to-Business&Citizen (G2B&C): The government leverages AI to support collaboration between citizens and businesses.

- G2B&C Dual Decision: The government supports an AI that receives active contributions from citizens and businesses while supporting the decision-making of these same agents.

- Conversational G2B&C: The government sustains an AI that receives active input from businesses, exchanges questions and answers with citizens, and supports the latter's decision-making.

Government-to-business (G2B): The government supports AI to support businesses.

- Direct G2B: The Government supports AI that supports companies' decision-making.

- Passive G2B: The Government supports an AI that supports companies' decision-making based on passive contributions from the last.

4. Results

4.1 Taxonomy for AI applications for public services

As presented previously, throughout the first iteration with a Conceptual-to-empirical approach, it was possible to conceptualize the taxonomy with the following dimensions: AI application, Problem Solved, Innovation, and Government Function (COFOG), which were already described. In the second iteration, we conceptualized a new dimension called collaboration support and its characteristics with an empirical-to-conceptual approach.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

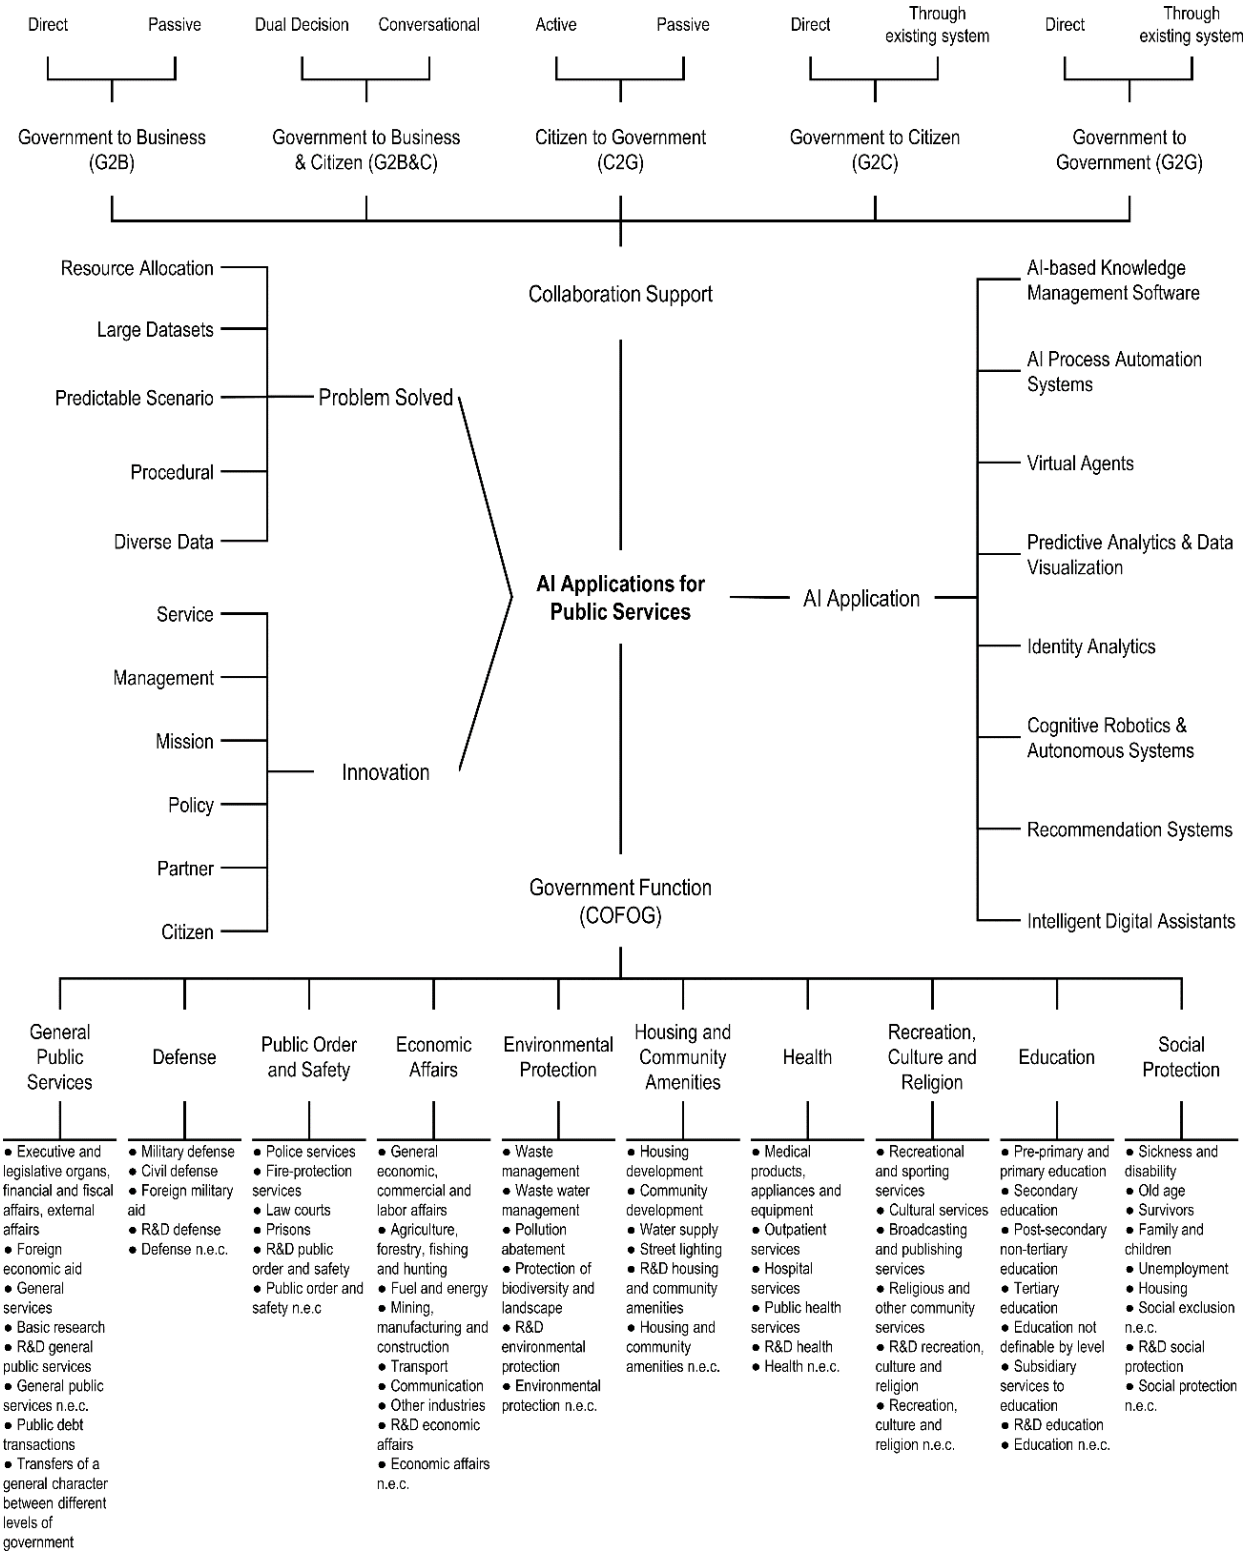

Fig. 4 - Taxonomy of AI applications in the Public Sector.

4.2 Answering the Research Questions

Once we conceptualized the taxonomy, we analyzed the documents identified during the review to demonstrate the usefulness and generalizability of the proposed taxonomy. In this way, we applied the taxonomy as an analytical framework to make it possible to answer the following questions below.

RQ 1: What are the types of AI solutions developed to support public services? And what problems do they solve?

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

The primary type of AI solution identified, as seen in Fig. **5**, was Predictive Analysis & Data Visualization, followed by AI Process Automation Systems in 41.75% and 22.33% of cases, respectively. All other types were below 10% of occurrence each, with a greater emphasis on Intelligent Digital Assistants (IDA) and AI-Based Knowledge Management (KM) Software, identified in 9.71% and 6.80% of cases, respectively.

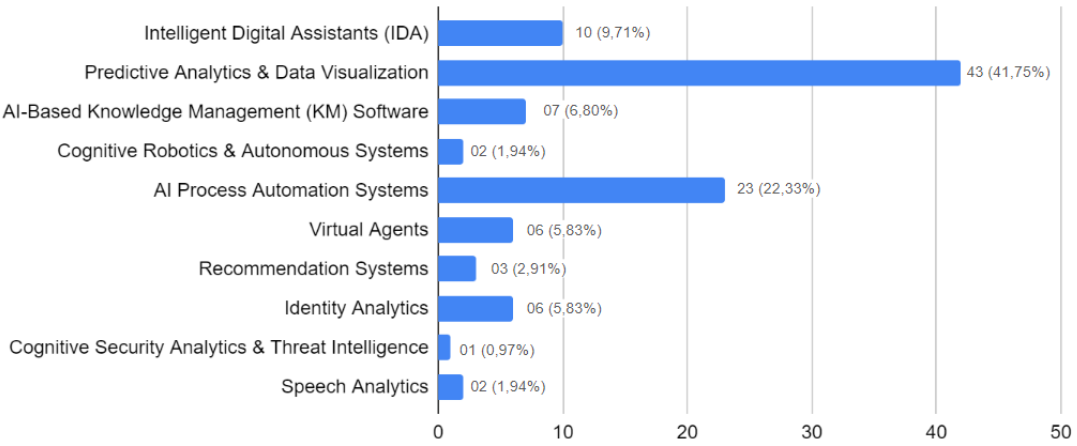

Fig. 5 - Distribution of types of AI applications in the publications analyzed.

As for the types of problems solved through AI, it is clear that the main problems addressed are the Diverse Data and Predictable Scenario problems, identified in 41.75% and 27.18% of cases, respectively. All other types were below 13% of occurrence each, with a greater emphasis on Resource Allocation, identified in 12.62% of cases, as seen in Fig. **6.**

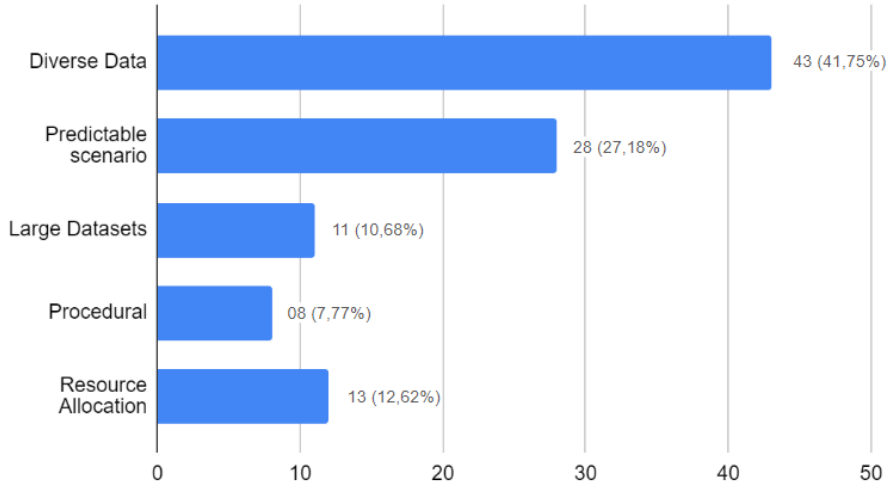

Fig. 6 - Distribution of types of problems in the publications analyzed.

Fig. **7** presents the correlation between the problems identified and the AI solutions employed. The same solution can be used to solve different problems, as in the case of Predictive Analysis & Data Visualization, which addresses four of the five types of problems encountered. The same problem can be solved through different solutions, as in the case of Diverse Data, which is addressed by nine of the ten types of solutions. Furthermore, somewhat obviously, the relationship between Predictive Analysis & Data Visualization solutions and Predictable Scenario problems stands out, with an occurrence of 24%. Next, the Predictive Analysis & Data Visualization solution stands out again, but now with the relationship with Diverse Data problems with an occurrence of 10.68%. Next, the relationships between the AI Process Automation Systems Solution and the Diverse and Procedural problems stand out, with 9.71% and 7.77% of the cases found.

RQ 2: Which government functions are using artificial intelligence? And what is the extent of these government functions covered by AI?

The central government function category that stands out is Economic Affairs, followed by Public Order and Safety, and Health, with 35.92%, 14.56%, and 14.56%, respectively, as can be seen in Fig. **8**. All other government function categories individually do not reach 9% of occurrences; if totaled, they reach 34.96%. As for the most prominent government function subcategories, we have Transport (#11) within the Economic Affairs category with 17.48% and then tied with 6.80%. We have the subcategories of Law Courts (#10), Agriculture, Forestry, fishing and hunting (#12), General, economic, commercial and labor affairs (#14), and Hospital services (#24) from the categories of Public Order and Safety, Economic Affairs, Economic Affairs, and Health respectively. Of all 28 subcategories, 16 (57.14%) present up to 1.94% of occurrences and a total of 21.34% of occurrences.

Fig. 8 - Distribution of Government Functions in the publications analyzed.

On the other hand, as can be seen in Fig. **9**, it is worth mentioning that the fact that some categories, such as Education and Defense, still seem to be poorly supported by AI, which may be a reflection of a limitation of this research related to the search protocol used. More specifically, in the case of Defense, for example, it may be that AI research is being published in other forums that were not reached with the strings used in the database consulted (Scopus). The same goes for the Education category, which, despite having many new features related to well-publicized AI applications, was not mentioned in this work, probably because the published AI applications for educational purposes are developed with a focus on the private sector that sees AI as a solution capable of bringing competitive advantage. Regardless of the limitations of this research, it is possible to note that seven of the ten government function categories have at least 50% of subcategories not supported by AI.

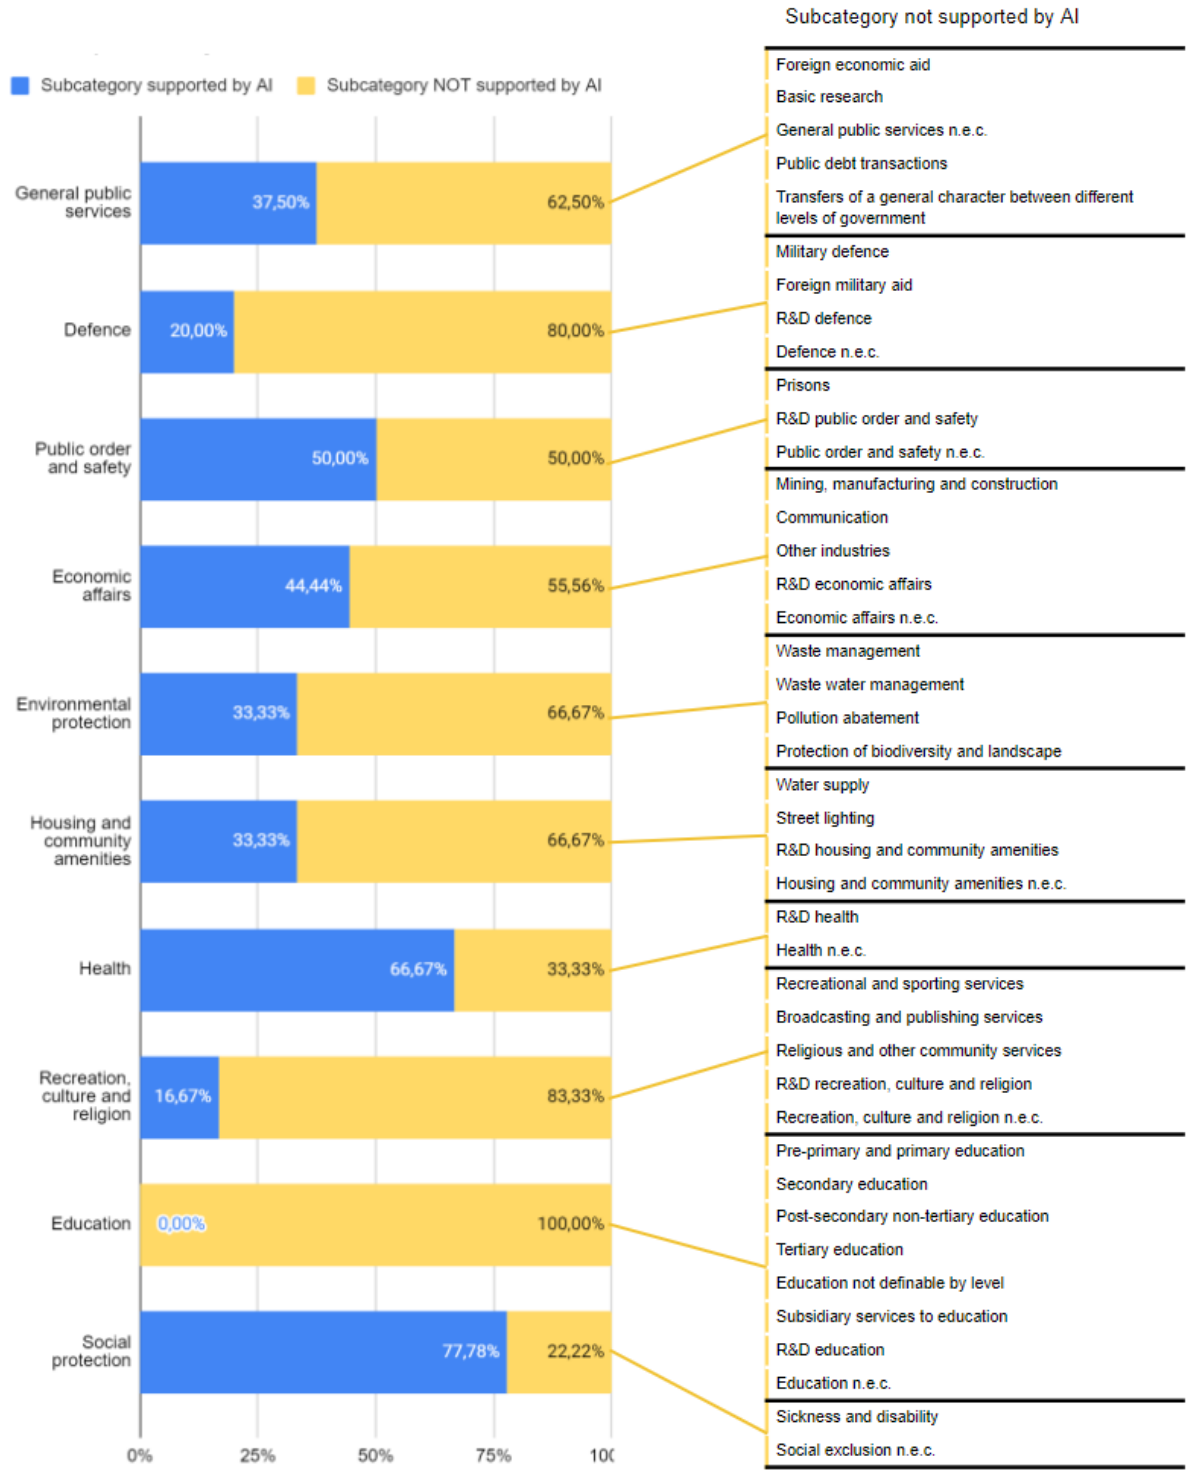

Fig. 9 - Distribution of the AI support in different Government Functions in the publications analyzed.

RQ 3: In what ways do AI solutions support collaboration in the public sector? And, what types of innovation are achieved through the implementation of AI in public service organizations?

The main collaboration category identified is Government-to-Government (G2G), followed by Citizen-to-Government (C2G), with 67.9% and 16.5% of occurrences, respectively, as seen in Fig. **10**. When we analyze the collaboration subcategories, we find that the G2G Direct subcategory is identified in 65% of cases, followed by C2g Active. All subcategories were identified individually, with a maximum of up to 4.9% of occurrences each.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

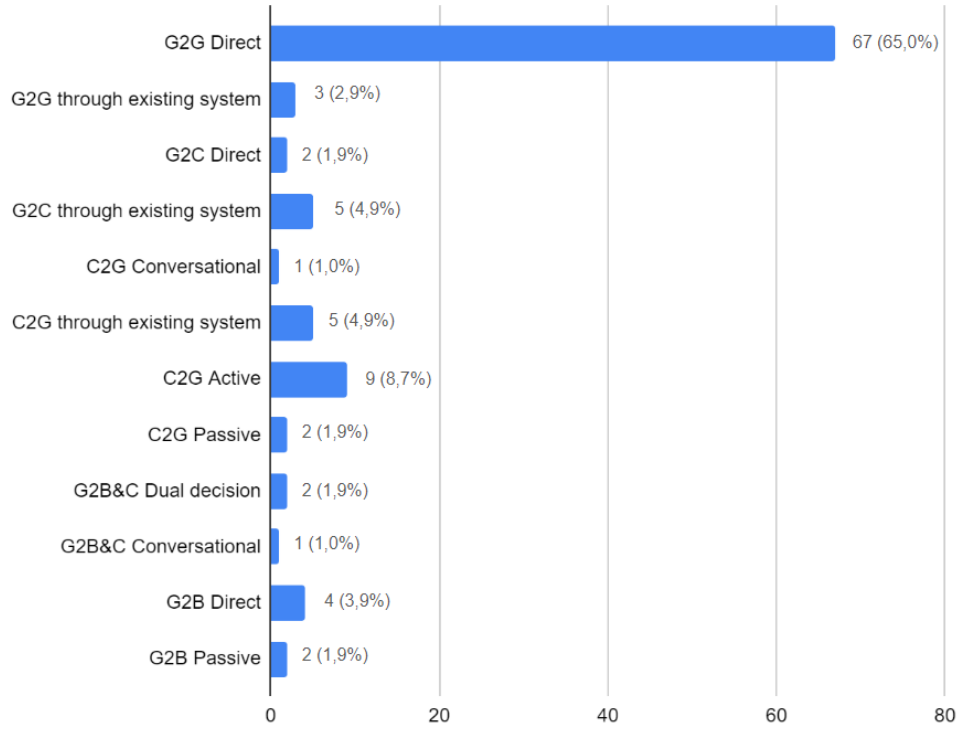

Fig. 10 - Distribution of types of Collaboration support in the publications analyzed.

As shown in Fig. **11**, regarding the type of innovation in organizations providing public services, innovations at the Management, Citizen, and Policy levels stand out mainly with 55.3%, 16.5%, and 11.6% of occurrences, respectively. The other types of innovation do not exceed 6.8% of occurrences each. It is also important to highlight that there is no direct relationship between the classification made regarding collaboration and the classification made regarding innovation. For example, the fact that collaboration involves citizens in some way does not imply that that innovation will necessarily be characterized as an innovation at the citizen level.

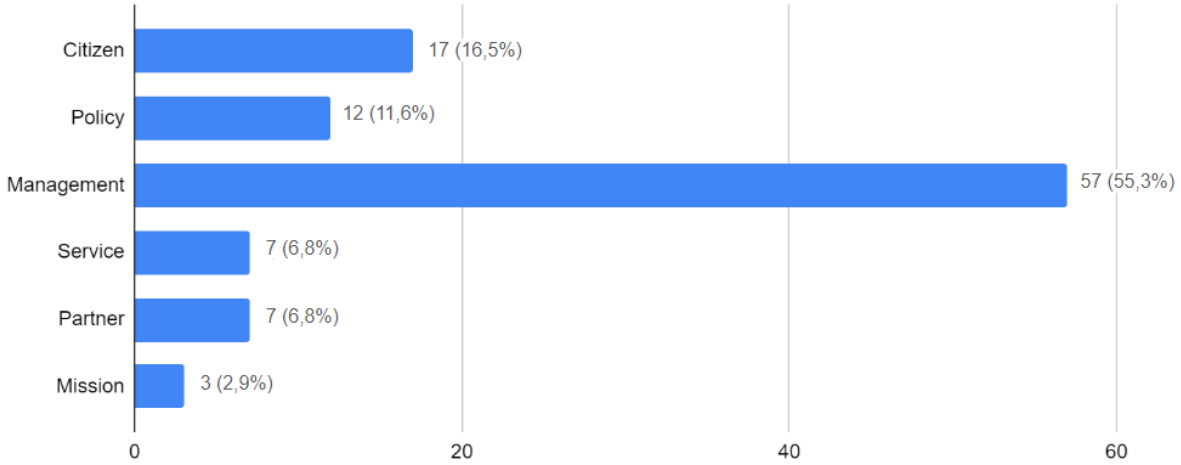

Fig. 11 - Distribution of types of Innovation in the organization in the publications analyzed.

5. Discussion

5.1 AI support beyond government administrative tasks

Based on the results of this research, AI in the public sector is primarily oriented towards addressing prediction problems and diverse datasets. Hence, the solutions often involve data visualization and predictive analysis, as well as the automation of repetitive processes. Furthermore, AI is predominantly applied in government functions such as Economic Affairs, Health, and Public Order. The reasons for the predominance of AI adoption in these areas are uncertain. One possible driver for acquiring these technologies may be the budget, as Economic affairs and Health are among the 4 COFOGs with the highest expenditure (Eurostat., 2024). However, this factor does not explain the high adoption of AI in the Public Order government function. The willingness to adopt AI technologies in

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

government depends on how officials perceive their positive and negative impacts on society in the long run and their familiarity with these technologies (Ahn and Chen, 2022). In this way, some of the impacts of AI have already been part of the collective social imagination for a long time, such as health and transport (inserted in economic affairs) as hopeful visions or the threat of surveillance, which denotes its power to be applied in the context of public order (Fast and Horvitz, 2017).

In terms of collaboration, it is evident that most of the collaboration achieved is within the government itself. The government tends to create technological solutions that it will utilize internally. When citizens are involved, they typically interact with AI systems to facilitate the production of information, knowledge, or decision support that the government needs. The government mainly develops AI solutions to its administrative and repetitive problems. These problems are often characterized by having extremely diverse, poorly structured, and fragmented datasets that require automation and predictive capabilities, particularly in sectors with large budgets.

While this focus on administrative efficiency is somewhat expected and natural, there is also a range of applications, problems, government functions, and innovative and collaborative efforts that, although currently in the minority, show significant potential for growth. For instance, government initiatives using AI applications can operate as platforms (O'Reilly, 2011) that impact citizens and businesses in crucial areas to enhance life quality and contribute to sustainable development goals (Singh et al., 2024). The concept of public services in this research is associated with Services of General Interest (SGIs), which are tasks and functions deemed essential for the quality of life of citizens, their well-being, and the overall functioning of society.

In this light, the diversity found in AI applications within the public sector offers alternative and innovative pathways for public services. These pathways differ from the traditional models we have seen and hold the potential for disruptive innovation, leading to new collaborative governance models. Such models could transcend the current dichotomy between market-based approaches focused on efficiency and those grounded in democratic values and the effectiveness of government work. This research underscores AI's potential to streamline administrative tasks and drive meaningful improvements in public service delivery, ultimately benefiting society.

5.2 How do Language Models and this Taxonomy connect?

When this research began, we had not yet experienced the boom of generative AI and the use of LLMs on a large scale. The rapid adoption of LLMs, which are machines with conversational and textual synthesis capabilities previously unfamiliar to much of the public, combined with extensive marketing from AI companies often backed by big tech, presents a vision of the future where LLMs are seen as a near step to Artificial General Intelligence (AGI). This AI hype already presents us with costs and threats that go opposite to what governments should pursue (Markelius et al., 2024). Furthermore, overestimating the ability to use LLMs in the public sector can generate a series of problems, and the risks of its use must be mitigated well (Analysis and Research Team, 2023).

In other words, AI lacks genuine understanding despite its ability to mimic human communication (Bishop, 2021). LLM does not indicate a direct pathway to AGI and its generalized problem-solving capabilities, but we can consider Biological and Quantum approaches to AGI (Mohammad et al., 2023). Therefore, we use Narrow AI (Berryhill et al., 2019), which refers to a machine with specific capabilities. In this context, the taxonomy presented in this work is especially valuable as it offers an analytical framework for classifying AI applications and types of problems, reminding us that LLM is not a panacea for the public sector challenges.

So, a question that might arise for those using the taxonomy is: how do LLMs fit into the dimension of AI application? First, it's important to understand how the specific LLM is primarily used to answer this question. Second, it's important to consider that a particular LLM could be part of a more robust architecture capable of presenting various capabilities. However, this is not unique to LLMs. Some solutions investigated in the review also pointed to certain multi-capabilities. Nonetheless, this is entirely different from claiming that LLMs, simply because they are LLMs, can perform all the diverse capabilities of various types of AI applications.

6. Conclusion

In this work, we investigated the support of AI-powered technologies in public services. Despite advancements in the field and academic efforts to understand the phenomenon, certain aspects related to the impact of AI adoption on innovation and collaboration in the public sector remain unresolved. A recognized need is also to create more robust classification structures for organizing knowledge about AI applications in public services. To address these gaps, we conducted a rapid review to identify how AI applications have been used, their impacts on innovation in the public sector, and the collaborative arrangements they have fostered among various stakeholders. Furthermore, we designed a taxonomy to classify AI applications in the public sector that was used as an analytical framework to answer the research questions.

The review results indicated that AI in the public sector is mainly used for prediction problems with diverse

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

datasets, involving data visualization, predictive analysis, and automating repetitive processes. These applications are primarily found in economic affairs, health, and public order. These are government functions with substantial budgets and where potential AI applications have been part of the collective imagination for a long time. Generally, governments develop AI solutions to their administrative and repetitive problems. However, fewer applications and collaborative arrangements were identified, suggesting potential growth for new AI adoption forms and possible public management disruptions, ultimately benefiting public service delivery and society.

Regarding the development of the taxonomy, two iterative cycles led to a result encompassing five dimensions along with a new conceptualization of collaborative arrangements based on a language of patterns of agents and interactions. Ultimately, these contributions are expected to support researchers, public managers, and tech companies in understanding and analyzing the complex domain of AI in public services to create and responsibly adopt new AI solutions in the future.

The main limitation of this study lies in the search protocol. Our search strings did not include broader terms such as "algorithm", nor did they draw from curated repositories like the OECD AI Observatory. Consequently, we may have overlooked relevant cases, especially AI applications in health, education, and defence that, although developed in predominantly private settings, are already being adopted by public organisations. Moreover, our collaboration framework (G2G, G2C, C2G, G2B..) aggregates interactions at a macro level and therefore does not adequately reflect public-private partnerships, citizen co-creation initiatives, or decentralised governance arrangements. Finally, ethical risks and challenges, algorithmic bias, transparency, accountability, and citizen trust, receive only limited attention.

Future work will address these gaps by (i) expanding the search strategy with additional descriptors and specialised databases to capture a more diverse set of cases; (ii) developing an extended version of this article that includes detailed case studies, demonstrating the taxonomy's applicability and refining it to accommodate intergovernmental and multi-stakeholder collaborations; and (iii) deepening the discussion on ethics and AI governance in the public sector by integrating systematic risk assessments and models of organisational, social, and environmental impact. These efforts aim to guide both the development of more responsible, explainable AI solutions and the formulation of evidence-based public policies.

Submitted: 31 January 2025, Revised: 26 March 2025, Accepted: 21 April 2025, Published: 19 May 2025

Abstract. The integration of artificial intelligence (AI) in local governments has gained increasing attention as a means to enhance civic engagement and streamline public participation. This study examines how local governments utilize AI-powered platforms for civic engagement, exploring the perspectives of public servants and developers on the implementation of AI, its benefits, challenges, and ethical considerations. With a qualitative approach, semi-structured interviews were conducted with developers, product designers, public servants, and decision-makers involved in developing and using the AI-powered platform for civic engagement initiatives. Thematic analysis was employed to identify key themes related to AI functionalities, user experiences, and governance challenges. The preliminary results reveal that four distinct types of AI applications have been employed, including AI-powered optical character recognition (OCR), AI-based content moderation, AI sensemaking, and AI-driven translation. These AI tools facilitate efficiency in data processing, enhance accessibility, and support decision-making. However, concerns regarding AI transparency, data privacy, and public trust remain significantly challenging. Additionally, public servants emphasized the need for AI literacy training and the development of ethical guidelines to ensure the responsible use of AI in local governance. This study contributes to the growing discourse on AI in civic engagement by offering insights into the practical and ethical dimensions of AI adoption in local governments. The findings underscore the need for policy frameworks, digital inclusivity measures, and ongoing capacity-building efforts to enhance AI-driven public participation.

Keywords. Artificial Intelligence, Local governments, Civic engagement, Technology adoption.

1. Introduction

As public sector organizations worldwide embark on digital transformation initiatives, the integration of Artificial Intelligence (AI) technologies has emerged as a distinctive force. At its core, AI refers to the development of computer systems capable of performing tasks that typically require human intelligence. In today's rapidly evolving technology landscape, AI has increasingly become integral to the functioning of the public sector, playing a pivotal role in optimizing government processes, decision-making, and service delivery (van Noordt & Misuraca, 2022). Such technologies are deployed in the public sector to support the smart allocation of public resources, assist citizens with chatbots, identify patterns, develop predictive analytics models, and enable sensor-based detection and prevention (Medaglia & Tangi, 2022). However, limited research has been conducted in this area compared to the research on AI adoption in the private sector. The public sector's slower pace of AI adoption, combined with the need for regulations and ethical oversight, makes it challenging to implement and study AI technologies on a large scale. Yet, it is critical to learn about AI adoption in a social and organizational context like

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

the public sector, where the performance value (e.g., reducing the cost and increasing the efficiency) does not always have the priority it has in the private sector; there is also public value (e.g., fairness and accountability) that needs to be considered (Sousa et al., 2019).

Civic engagement, in general, is defined as individual or collective forms of action designed to identify and address matters of public concern (Axelsson et al., 2010). It encompasses a wide range of activities through which individuals or groups seek to influence public policy, improve their communities, and ensure that their voices are heard in the decision-making processes. Examples of civic engagement include voting, attending town hall meetings, participating in local boards or committees, volunteering for community projects, petitioning (Dumas et al., 2015), and engaging in public advocacy (Uslaner & Brown, 2005). Since the last decade, digital participatory platforms have enabled governments to engage citizens more effectively, promote transparency, and foster collaboration in decision-making processes (Falco & Kleinhans, 2018). While digital government research has examined e-participation tools, AI-driven engagement remains underexplored. It is essential to explore how digital participatory platforms harness AI technologies to further advance democratic participation.

To address this gap, this research endeavors to investigate the use of an AI-based platform for civic engagement in local governments when delivering public services. We adopted a socio-technical perspective to examine the intricate interplay between a specific social system (i.e., local governments) and the technological infrastructures (i.e., AI). This approach posits that technological artifacts and social dynamics are mutually constitutive, meaning that technologies are designed, implemented, and used within specific social contexts, and, in turn, they shape social practices, organizational structures, and human behaviors (Kling, 2007). We aim to provide a comprehensive understanding of the socio-technical dynamics surrounding the implementation and use of AI in local governments, facilitating more informed decision-making and promoting responsible AI deployment for the public good.

In this study, the GoVocal platform was selected for its AI features, which are designed for civic engagement in public services. The local governments in the US that are using the GoVocal platform were exhaustively sampled for an interview study. To gather data about practices and perceptions of AI for civic engagement, we talked to 1) the developers, product designers, and customer support specialists from the GoVocal platform on the development side, and 2) the public servants who work with GoVocal's AI features in local governments on the implementation side to triangulate the investigated phenomenon from different perspectives. Compared to prior studies that investigate how citizens as users at the front end respond to digital participatory platforms, this study focuses on public servants who are users of the GoVocal platform at the back end.

The research questions we seek to address in this study are: **RQ1:** What AI features have been developed and used to enhance civic engagement in local governments? **RQ2:** What are the benefits, challenges, risks, and ethical considerations of AI adoption for civic engagement in local governments?

2. Literature review

The adoption and use of AI in governments worldwide are growing rapidly. Governmental agencies at local, regional, and national levels have begun to pay close attention to AI applications being developed in commercial settings and envision utilizing AI to support administrative processes and deliver public services (Ahn & Chen, 2022).

2.1 AI capabilities in governments

AI capability, derived from the concept of IT capabilities, suggests that organizations need to leverage AI, as well as other complementary resources, to realize value rather than solely identifying degrees of AI adoption (Mikalef & Gupta, 2021). AI capability consists of complementary AI-related tangible, human, and intangible resources. Such conceptualizations of an organization's ability to leverage technology provide more accurate representations of the value that can be expected, as they encompass the intangible aspects that enable technological innovations to be implemented (Mikalef et al., 2022). Therefore, AI capability builds on the necessary technical and organizational elements required to effectively deploy AI resources to achieve prioritized objectives. Mikalef and Gupta (2021) define AI capabilities as "the ability of a firm to select, orchestrate, and leverage its AI-specific resources." (p.4) This definition denotes that an AI capability goes beyond just selecting, or else adopting AI, and includes the capacity to bring AI-related projects to fruition.

When investigating AI capabilities in governments, Medaglia and Tangi (2022) found that requirements indicated as important by public managers involved in public service in European AI projects largely overlap with classic drivers known from well-established research in e-government, which include both internal factors, such as middle and top management commitment and external factors, such as the availability of IT resources, government support at different levels, citizen support, and business support. Yigitcanlar et al. (2023) investigated how the adoption of AI would impact local governments' abilities to enhance services and establish user expectations, using semi-structured interviews with city managers from Australia and the United States. On the one hand, the adoption

of AI may lead governments to learn from and cultivate their own AI systems, particularly those governments that are at the forefront of experimenting with AI and have the necessary leadership and funding support. On the other hand, some governments that cannot afford or are unprepared to adopt these systems, prioritize them, and train to use them will be left behind. This suggests that the disruptive impacts of AI adoption are predicted to create a widening knowledge and skill gap between local governments, with those that cannot adopt it likely to lag behind.

Moreover, prior literature has highlighted the importance of having a robust technical infrastructure in place to support the deployment of AI (Zuiderwijk et al., 2021). This technical infrastructure is necessary to obtain, manage, and store the various data required to train AI. AI is typically integrated into existing IT systems and is never used in isolation, which requires organizations to have a basic IT infrastructure with suitable hardware and software. Local governments should, therefore, have access to an infrastructure with high connectivity and enough bandwidth, processing power, server hardware, networks, and database management technologies to facilitate the storage and analysis of the large datasets needed to develop AI. Alternatively, in the case of cooperating with a third party for AI services, local governments should initiate the guidelines and set up the principles before employing external AI services.

Additionally, utilizing AI in local governments requires that public servants and citizens possess a certain level of digital literacy. Hence, local governments in some countries provide training to citizens of all ages and public servants on the basics of computer use, navigating the Internet, and searching for information. Increasingly, some also provide specialized knowledge on AI. These initiatives enhance computer literacy and support individuals' ability to leverage existing work on AI for their own personal and professional purposes. For instance, the French Institute for Public Management and Economic Development (IGPDE), which forms part of the French Ministry of Economy and Finance, offers many different training courses, including short, one-day sessions such as "Digital Transformation of the State and Data" and "Artificial Intelligence, Data Science: New Economic Challenges." These aim to equip public servants with a basic understanding of AI and its opportunities and challenges. One more example is the government of Singapore, which offers AI workshops open to public officers and middle to senior managers. It aims to increase digital literacy and provide foundational knowledge about the potential of AI for public work and public organizations.

2.2 The benefits and challenges of AI in governments

The use of AI in government could bring a range of benefits. Three primary ones can be summarized as **1) Improving internal efficiency:** AI applications have the capabilities to perform specified tasks (e.g., extracting structured data from relevant documents) and consequently free up precious cognitive resources of public workers, which can then be allocated to tasks of higher added value (Loi & Spielkamp, 2021). This reallocation enables the government to concentrate its scarce resources on tasks where human workers excel, such as problem-solving activities that require empathy, creativity, and innovation. **2) Enhancing the capacity of decision-makers:** A natural benefit of applying AI techniques to public decision-making is the ability of AI algorithms to consider a greater number of variables, as well as the increased granularity and accuracy of the actions that AI systems can recommend. In cases where citizens' opinions are important, AI-powered simulations can model policies and their effects, and these simulations can be used to support discussions among citizens (Charles et al., 2022). In addition, the potential benefits could be perceived as impartiality, which decisions delegated to AI-powered algorithms can provide. For instance, AI may be perceived as not having the same biases as humans do. Local-level bureaucrats in public sector organizations face the possibility that various factors, such as corruption, organizational politics, and personal biases of any type (e.g., gender, race, and socio-economic status), may influence their decisions (Alon-Barkat & Busuioc, 2023). **3) Promoting citizen-government interaction:** On the one hand, AI can enhance existing service interfaces or create new ones with more usable and human-centered applications. For example, implementing chatbots to collect citizens' opinions and facilitate deliberative interaction with natural language processing and text analysis (Henk & Nilssen, 2021). On the other hand, AI can potentially increase citizens' trust and participation in public sector activities. For instance, AI functions as a nudging device, prompting humans to consider the value implications of their decisions or to reflect on when to make decisions that are perceived as more equitable, fair, and legitimate, thereby increasing trust (Aoki, 2020). Scholars have also pointed out that the adoption of AI within government institutions supports organizations in becoming more transparent and open to citizens, as well as more participatory with other sectors (van Noordt & Misuraca, 2020).

While the benefits of AI in government are significant, there are also potential risks to consider when seeking to minimize the unintended consequences, which include: **1) Algorithmic bias**: While the ability of AI applications to recognize patterns can be beneficial when segmenting populations, for example, in welfare service provision or when addressing anti-social behavior, it can also amplify discriminatory biases already present in human-led assessments (Gualdi & Cordella, 2021). Predictive algorithms can favor groups that are better represented in the data used to train algorithms. As algorithms can play a role in the propagation of existing social biases across gender, race, sexuality, and ethnicity, AI could thus participate in and potentially increase systematic and unfair treatment of citizens based on social biases (Zuiderwijk et al., 2021)—an outcome that is in direct conflict with the mission of governments to provide unbiased and equitable treatment of citizens under the rule of law. **2)**

Algorithm opacity: The increasing complexity of AI systems, especially deep learning solutions with more and more layers and parameters, reduces the capability of human operators to trace outputs back to specific inputs, making it potentially impossible to account for specific AI-driven outcomes clearly, and to correct actions with unintended consequences (Morley et al., 2020). The broader consequences of this phenomenon have been referred to as creating a "black box society" (Wirtz et al., 2020) and have profound implications for governments, which, by definition, are bound to citizens' expectations of transparency and accountability. On the other hand, AI systems can shift public servants' responsibility for accountability, posing challenges in the legal and political liability dimensions (e.g., who is responsible for damage to a citizen stakeholder if the decision has been outsourced to an AI application?) (Wihlborg et al., 2016). **3) Invasion of privacy:** The harvesting of large volumes of personal data required to fuel AI solutions poses a risk of infringing on the privacy of citizen users (Zhang et al., 2021). Any AI algorithm, regardless of its area of application, can produce relevant outputs only if trained with an appropriate amount of data. Such data might be personal, sensitive, or inappropriately collected or managed. Additionally, the use of AI in governments may entail the risk of extensive surveillance (Valle-Cruz et al., 2019). Addressing these risks requires a comprehensive and ethical approach to the development, deployment, and governance of AI systems in governments.

2.3 Public servants' and developers' perceptions of AI in governments

Public servants play a critical role in governments' adoption and use of new technologies, and their attitude and willingness to utilize them are crucial in creating a sustainable and meaningful digital transformation. Based on survey results from current government employees in the U.S., Ahn and Chen's (2022) analysis reveals that the willingness to implement and use AI technologies in governments is contingent upon a series of positive and negative perceptions about the new technologies, the long-term outlook on the role of AI technologies in society, and their familiarity and experience with using some form of AI applications in the past. Specifically, Ahn and Chen (2022) found that when asked if the government should consider using AI to improve public service, a vast majority (77%) agreed or strongly agreed, while 10% disagreed, and 11% remained neutral. When asked to choose one area of their work that they perceived that AI would improve, the majority of the respondents said that its use would increase the efficiency of their work (55%), improve service quality and effectiveness (21%), and relieve them of mundane and repetitive tasks (19%). The results also indicated that government employees were mildly concerned with AI taking discretionary authority away from their work (55%), while 45% were not concerned or were uncertain about AI's role in their discretionary authority. Also, a correlation was found between exposure to AI and the degree of support for AI in governments, where the employees who had used AI were likely to show a greater degree of support for implementing AI in their agencies.

However, government employees' perceptions of the transformative potential of AI for improving government transparency reduced their willingness to adopt AI in government, reflecting resistance to opening governmental processes to the public. Among the perceived concerns, the concern over AI's ability to make sound ethical and moral judgments had a statistically significant influence on the willingness to use AI in government (Ahn & Chen, 2022). Regarding the perception of the role of AI in society, its ability to surpass human intellectual abilities, its role as a competitor to humans, and the perception of its eventual benefit to humanity had statistically significant impacts on respondents' willingness to use it. Among the types of government work and the demographic characteristics of public servants, party affiliation with the Democratic Party was negatively associated with the willingness to adopt, while working in state government had a positive impact. Middle managers were less willing to support AI technologies in government, while male respondents were more likely to support them than female respondents (Ahn & Chen, 2022).

Henk and Nilssen's (2021) empirical findings on the use of AI in Scandinavian public services showed that implementing AI-based chatbots in day-to-day activities alters rather than completely replaces the existing jobs of frontline service workers. For example, implementing AI results in the need to improve the empathic and intuitive skills of service workers. This may occur because public servants may need to respond to personalized inquiries that require close human interaction, rather than handling routine requests that can be automated. Additionally, the organizational culture has not undergone significant changes due to the implementation of AI. Employees perceived the chatbot as an assisting "new colleague" rather than a breakthrough technology that disrupted everyday activities. The findings suggest that instead of creating a new culture, managers created an understanding of the chatbot's limitations and integrated it into the existing culture. Moreover, the participative leadership style of managers facilitated the uninterrupted implementation of the application by promoting cross-departmental cooperation and fostering a positive attitude toward the change.

Figueras et al. (2022) examined how AI developers perceive ethical issues concerning AI design and how they interpret and put them into practice by conducting interviews with AI practitioners working in or for public organizations in Sweden and found four different kinds of tensions: 1) tensions in respondents' ranking of the ethical principles, which means that practitioners valued ethical principles differently; 2) tensions in the interpretation of ethical principles, which means practitioners interpret ethical principles in different ways; 3) tensions in enacting ethical principles, which means practitioners embedded ethical principles in design in

different ways; 4) tensions between national and professional practice, which means national governance may clash with the AI design practice and ethical principles on certain occasions. Interviews with chatbot designers revealed that they prioritize specific value dimensions for public services (Makasi et al., 2022). The first level comprises six dimensions, which are discussed as high priorities for both basic and advanced chatbots in the public sector: efficiency, effectiveness, user orientation, professionalism, adaptability, and trust in government. The second level consists of five value dimensions cited as critical to public services, particularly in relation to chatbots that retain user profiles, which is typically the advanced type of chatbot. These are privacy, legitimacy, accountability, acceptability, and social license. Finally, the third level consists of four dimensions acknowledged as highly important in the overall performance management of all chatbot initiatives in the public sector: openness, sustainability, fairness, and collaborative intelligence. These value dimensions shed light on the ethical design of AI.

3. Methods

3.1 Research subject

When examining the use of AI in local governments, we identified a specific platform (i.e., GoVocal, see Figure 1) that incorporates AI features adopted by multiple local governments in the US. The investigated phenomenon in this research is the use of this platform, particularly its AI features, in local governments for civic engagement initiatives when delivering public services. GoVocal is a digital platform designed to empower citizens and enhance civic engagement by fostering meaningful dialogue and facilitating constructive interaction. It serves as a digital town hall where residents can voice their opinions and contribute ideas to a wide range of civic projects, including urban planning, environmental sustainability, and social initiatives. With its technological affordances and AI-based features, such as online surveys, idea generation, interactive mapping, and discussion forums, the platform supports diverse forms of citizen participation.

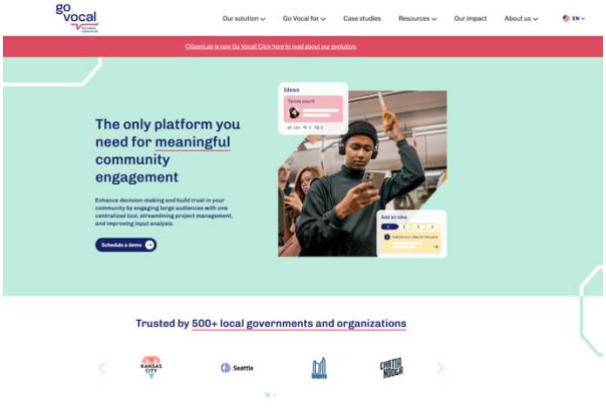

Fig. 1 - Homepage of the GoVocal (formerly CitizenLab) website (https://www.govocal.com/).

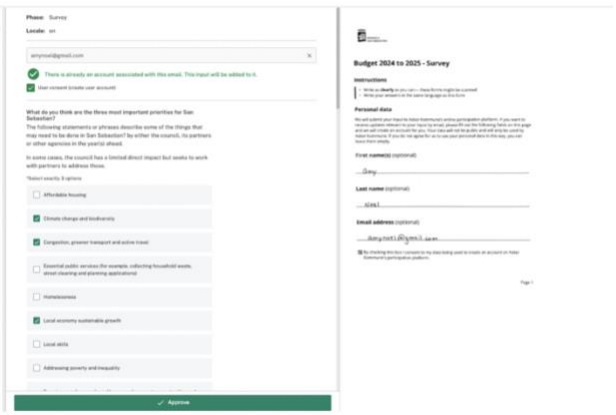

Fig. 2 - The user interface for the AI-powered OCR.

AI features developed and provided by GoVocal include:

1. AI-powered optical character recognition (OCR) is used to scan and digitize the uploaded paper participation at scale by handling a wide variety of document layouts and handwriting with minimal manual intervention (see Figure 2).

2. AI-based content moderation automatically assesses and filters online content by identifying abusive, toxic, harmful, or other inappropriate expressions from user-generated posts, proposals, and comments on the platform.

3. AI sensemaking is an AI-driven tool that analyzes, interprets, and derives meaningful insights more quickly across vast amounts of textual and quantitative data collected during engagement projects, identifying patterns and contextualizing results (see Figure 3).

4. AI-driven translation leverages large datasets and sophisticated algorithms to learn linguistic patterns, content, and nuances across multiple languages, enabling the automatic conversion of text from one language into another.

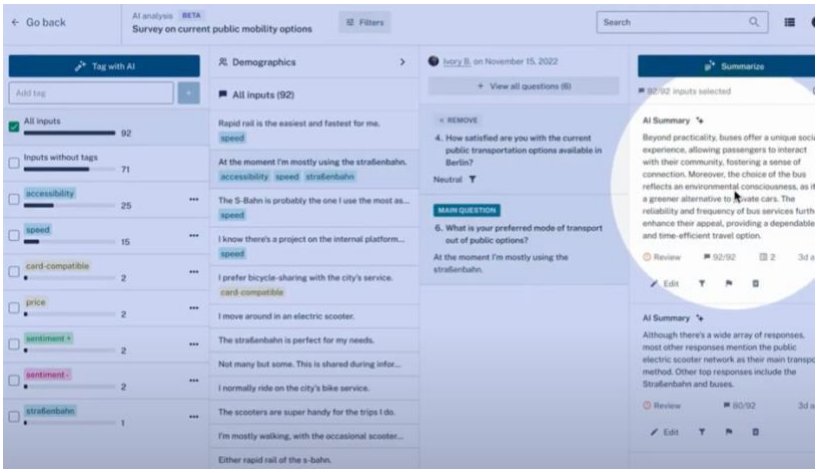

Fig. 3 - The user interface for the AI sensemaking tool.

3.2 Data collection

According to GoVocal's website, the platform has been used in a wide range of countries in Europe and North America. In this study, all the local governments in the US that were using the platform by the time the interview study was conducted have been exhaustively sampled and contacted (see Table 2). Interviews are particularly helpful when aiming to explore the use of AI for civic engagement in local government as a complex yet novel social phenomenon, and to gather in-depth information to understand participants' lived experiences, perspectives, and opinions (Gubrium et al., 2012).

Tab. 1 - Local governments in the US that use the GoVocal platform and their population size based on 2023 census data.

Location	Population size	text
Carlisle, PA	22K	https://carlisle.govocal.com/en/
Lancaster, PA	57K	https://engage.cityoflancasterpa.gov/en/

Hyattsville, MD	20K	https://hellohyattsville.com/en/
Kansas, MO	510K	https://speakeasy.kcmo.gov/en/

We conducted a series of semi-structured interviews with two groups of stakeholders: 1) developers, product designers, and customer support specialists from the GoVocal platform, and 2) public servants and decision-makers in local governments who work with the GoVocal platform and its AI features for civic engagement. The interviews aim to gain contextualized information about the actual design and implementation of the AI features provided for civic engagement. Additionally, the perceptions of benefits, challenges, and ethical considerations associated with using AI in local governments will be investigated (please see the interview questions in the Appendix). In this preliminary finding, we report the results of our interviews. We interviewed three GoVocal developers, product designers, and customer support specialists, as well as seven public servants (one to two from each local government, based on their availability).

3.3 Data analysis

The audio-recorded interviews were transcribed, and a thematic analysis was conducted with a grounded theory approach (Glaser & Strauss, 1967). This method involves analyzing patterns or themes by closely examining the data line by line to identify concepts or ideas, which will then be labeled with descriptive codes. The grounded theory approach avoids reliance on preconceived theories or hypotheses, allowing for the exploration of the

complexity and richness of the phenomena under study. The NVivo application was used for the analysis. First, we conducted an open coding guided by the research questions on 10-20% of the corpus to start developing the codebook. After that, each author separately coded the same sample using a well-defined codebook and then calculated the intercoder reliability. The percentage of agreement exceeds 90% when comparing our coding results, and disagreements were resolved through discussions and re-coding. We didn't use Cronbach's alpha because the unit of coding is not consistent, as it is not always on the sentence level, and many codings were conducted on the paragraph level, which made the calculation of Cronbach's alpha a bit difficult. The codebook was ready when one of the authors completed the coding for the rest of the corpus. The identified codes for the thematic analysis are shown in Table 2.

Tab. 2 - Codebook for the thematic analysis of interview transcriptions.

Codes	Descriptions
AI features	The features provided by the platform, designed with AI technologies by developers and utilized by public servants in local governments for civic engagement, include existing ones that have been developed and implemented, as well as future ones that are being envisioned and anticipated.
Civic engagement	The understanding of civic engagement in local governments from the perspectives of developers and public servants, such as the objectives and goals.
Evaluation	The evaluation of AI features' performance from the perspectives of developers or public servants, for example, their effectiveness, usability, and potential public value in creating civic engagement in local governments.
Benefits/Challenges/ Risks	Benefits, challenges, or risks of developing, implementing, and using AI features for civic engagement in local governments.
Ethical consideration	Considerations of ethical issues like fairness, bias, transparency, accountability, data privacy, and security and how they are addressed in the development, implementation, and actual use of AI features for civic engagement in local governments.

4. Findings

4.1 What and how are the features developed and used for enhancing civic engagement?

Platform developers and public servants described how various AI features were designed and utilized to enhance civic engagement in local governments, including AI-powered OCR, AI-based content moderation, AI sensemaking, and AI-driven translation.

First, platform developers explained the motivation for developing AI-powered OCR was that when talking to public servants to learn about their needs for a digital platform enhancing civic engagement, public servants complained that it was quite time-consuming to transcribe all ideas after collecting surveys offline while "*offline consultation is important to engage senior citizens or people who have lower digital literacy and have difficulties with accessing digital surveys online*." (P5) Hence, the platform provided the AI-powered OCR to help with speeding up the transcription by extracting data from scanned PDF/Excel documents to generate structured input. This feature utilized AI technology to make engagement more inclusive by enabling public servants to efficiently synchronize offline insights and input. While traditional OCR is a rule-based technology suitable for basic text recognition, developers have noted that "*AI-powered OCR leverages advanced machine learning techniques to deliver higher accuracy, contextual understanding, and adaptability in complex scenarios*" (P8). AI-powered OCR can learn and adapt to different fonts, languages, and writing styles. It also handles low-quality or distorted images more effectively and recognizes text from complex layouts, such as tables or multi-column documents.

Second, AI-based content moderation automatically reviews and manages citizens' inputs on the platform by unpublishing content that is non-compliant with established community guidelines. The developers (P7) mentioned that they have built "*profanity blockers that contain lists of offensive words for governments across Europe, the US, and Latin America*." With AI technologies, content moderation seeks to foster civic engagement by creating a more respectful online environment that encourages public participation. One of the public servants (P1) mentioned, "*What I always tell people is I was amazed at the depth of thought and quality of the answers. It was not like a Facebook forum where everyone just said and argued nasty things. Of course, at the back end, we see email notifications about the red-flagged posts removed by the AI moderation, but at least people who go to the platform for a civilized discussion don't have to build their opinions on that.*"

Third, the AI sensemaking tool automatically extracts useful insights from large volumes of citizens' input and generates summaries for public servants. The developers pointed out that government agencies spend far more time analyzing, communicating, and acting on data than gathering it; however, they often lack sufficient time to analyze the data, which ultimately motivated the platform to develop this AI sensemaking tool. For example, one of the developers (P6) mentioned, "*Our platforms get like thousands of comments and inputs from residents. It's really hard for local administrations to make sense of them. So we even had people saying that 'I just can't process it at all, and sometimes I only process 20% of the input.'*" Another developer (P7) added, "*It's not only sad, but as a city, you have a responsibility towards your constituents, and you are only reading 20% because you don't have time. So that's why we started developing AI sensemaking that helps summarize communities' input topically, sentiment-wise, and controversy-wise*." When talking to the public servants, one of them (P2) described this time-consuming process for analysis and lack of skills in dealing with vast amounts of qualitative data as "*we are surrounded by data, but too often starved for insights*." The AI sensemaking tool offers functionalities such as auto-tagging keywords, generating summaries, and providing references to original inputs for human validation. Public servants can filter responses based on specific answers and ask follow-up questions to gain a deeper understanding of the data. Moreover, this tool analyzes the most popular keywords or concepts discussed within the community, and then visualizes the most popular keywords on a map relative to their importance, clustering them together with keywords that appear together repeatedly. The visual representation, in addition, helps public servants quickly understand what people are discussing and then "*find out what the trends, changes, and gaps are in the current project and decide whether a detailed analysis is necessary for the next steps*" (P4).

Fourth, like AI-powered OCR helps maintain offline accessibility, a public servant emphasized the importance of language accessibility, particularly in cities serving communities with diverse cultural and linguistic backgrounds. P4 explained, "*As a city, as we communicate with citizens, we don't want to spend extra money to translate everything, so it's not useful for us unless the translations are built into the platform that makes everything accessible to people in different languages*." The AI-driven translation was very important as the GoVocal platform is a company based in and serving many European countries. One of the developers (P8) said, "*We serve, I think, around 17 different languages on our platform today. We also sometimes have platforms that are using multiple languages. We initially struggled with limited algorithmic resources for translation, but now we are utilizing a combination of ChatGPT 4 and Clouds, which are becoming increasingly proficient in multilingual tasks. So, as developers, we need to make sure that the platform generates their answers in the right language by specific prompt engineering to make it happen*."

4.2 The benefits and challenges of adopting an AI-based platform for civic engagement in local governments.

While using the AI features embedded in the platform, public servants expressed positive feedback, highlighting the user interface, effectiveness, and interaction design. For example, they noted improvements in efficiency, extended capacity, and the ability to accomplish more with limited resources, which they viewed as key factors in justifying the implementation of AI to government stakeholders. "*Because we are a quasi-governmental organization of two to six people, efficiency is the drive. That's how we convinced the local governments that we need to implement, utilize, and leverage AI tools, as we require greater efficiency and increased capacity for investment. I would simply say the investment is 100% worth it here with this platform. We were able to do more with less.*" P9 from the same institute added, "*In terms of convincing the stakeholders, it's very important for them to see the actual product and understand how it works. It gives them a clear picture of what results this product can bring to the organization*." (P3)

Furthermore, public servants appreciated the referencing functionality of the AI sensemaking tool, noting that its interaction design saves time, facilitates the verification of information sources, and enhances the reliability of the generated summaries. One of the public servants (P4) mentioned, "*Let's imagine a summary of 2,000 inputs that we've received. We will see a little bubble, sometimes with 20 bubbles or 30 bubbles, and by clicking on each bubble, we can actually see where that little insight or sentence originates from. Then we go back to the original source of the input for human verification.*" (see Figure 4)

Besides its summarization functionality, the AI sensemaking tool enables public servants to pose specific questions regarding residents' input using various prompts. One of the public servants (P10) reflected on this design and said, "*Most people's experience, like at least their greatest exposure to AI, is ChatGPT, so you get used to this chat box and just type in your questions. I'm surprised to see we can also ask questions based on how this AI tool understands the residents' input.*" This chatbot-like design for interaction lowered the entry barrier for individual public servants to effectively leverage AI capabilities. Overall, with the various tools and AI features provided by the platform, public servants feel more empowered when analyzing data, as some may lack the skills or expertise to handle large volumes of qualitative data or interpret survey results. This is especially beneficial for smaller local governments with limited human resources dedicated to civic engagement initiatives. P2 elaborated, "*It's useful when going through all the data because I'm not a statistician, I'm not whatever. It saves time when pulling out keywords and recurring themes, which I previously had to do manually by reading everything. So that kind of thing makes the handling of the data a little easier, especially being a one-person team for all the public engagement stuff*."

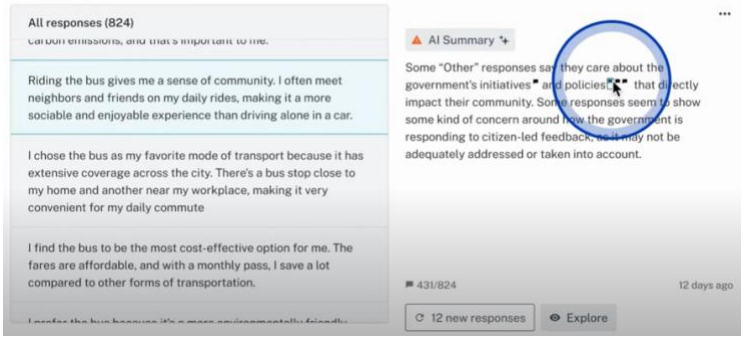

Fig. 4 - AI summarization enables users to verify the source of the input.

The first challenge identified by public servants is the accuracy of AI-generated summaries, which highlights the need for careful consideration of which projects are suitable for analysis using AI tools and which require alternative approaches. According to the interviews, public servants believe that AI performs effectively in projects where its primary role is to extract information and keywords from citizen input. However, they prefer manual analysis for projects that demand deeper contextual understanding or when capturing the sentiment of the input, which is particularly important. For instance, P5 described their strategy utilizing AI summarization, "*What I'm worried about with AI is that they're going to give me the information, but because this is such a contentious issue with people holding polarized opinions, what I really want to understand is the context and people's feeling when they're typing things out. I want to know if they are really against it. Are they pissed off? Do they feel heard?*" P9 also expressed concerns over the quality of data being produced by AI summarizations and emphasized that human verification is essential: "*It's a great tool, but it still needs a human to review it. Make sure that it is, in fact, correct and accurate. And I think people rely too heavily on just saying, 'Oh, well, the tool did it.' That would be my concern that people would forget that it still needs oversight and fix things before it goes out into the world*."

The second challenge pertains to public servants' AI literacy, which is crucial for ensuring the effective and ethical application of AI features in civic engagement within local governments. One of the public servants (P10) said, "*There were elements about it that were not as user-friendly as it could be*." In addition, public servants may resist using AI features due to a lack of understanding, as "*AI algorithms function as so-called black boxes,*" according to one of the developers (P8). Therefore, the platform provided onboard training for public servants when they first adopted the AI features and they found it "*very helpful to get a basic idea about what's going on and how to process citizens' input*." (P4) One of the developers (P6) added that, "*The training sessions don't mean to tell public servants how we developed the platform and how we're using AI models to make everything happen. They only need to learn how to analyze the data with all AI features, and we emphasized many times about human moderation so that they also know how to double-check with original inputs and summaries generated by AI*."

Challenges related to the digital divide, fairness, and inclusiveness also emerge as significant concerns. Although the platform was designed to enhance civic engagement, public servants noted difficulties in ensuring that it serves all members of the community. Limited access to the internet or digital devices among certain groups restricts their ability to participate, thereby hindering the platform's inclusivity. P1 commented, "*Obviously, the only limitation is if you're going to be in an area where there may be questionable internet access, how do you reach those residents? When you're talking about rural parts of the United States, due to the cost barriers, people might not have access to the internet, or they don't even have the infrastructure*." Therefore, public servants also adhere to their offline engagement strategies. As P2 stated, "*When we do major projects, we've also had either face-to-face meetings, or mailers, or door hangers, especially targeting those areas that we know are low tech and not okay with online show-ups*." To further raise public awareness about the online platform for civic engagement, public servants shared their methods of directing people from traditional engagement channels to the platform. For example, P9 said, "*We are simultaneously using old-school posters that point people through a QR code back to that platform. We will issue a press release to the local newspaper. We'll put it on our social media*."

4.3 The ethical considerations of AI adoption for civic engagement in local governments.

The application of AI for collecting and analyzing civic engagement data introduces potential risks related to the use, storage, and sharing of personal information. When asked about data security and privacy issues, public servants shared different perspectives. For example, one public servant highlighted the importance of data ownership and the ability to export and retain data after the contract expires. As P1 said, "*There were very few platforms that would allow the municipality to keep the data or to export the data when the contract with the platform expired. But this platform allowed us to export all the data and keep it, even if the municipality chooses not to use the platform any longer*."

Regarding the risk of data breaches, where unauthorized parties may access sensitive or confidential information,

most public servants did not express significant concern. This was primarily because sensitive data were not stored or shared online, or due to the perception that the platform operates similarly to other commonly used platforms. P10 explained, "*Not in the sense that we were asking any questions that would ask for social security numbers, bank account information, or healthcare data. Nothing felt where the residents, at least through the platform, were providing a lot of information that would put them at a data breach type of problem*." P5 added, "*Since anything online is going to have the possibility for a data breach, we weren't worried about this any more than you'd be worried about residents using any type of platforms that are exposed to hackers. I think it's a fair assessment*."

Furthermore, developers outlined the measures implemented to safeguard user data on the back end and explained that, when utilizing APIs from large AI models, they establish contractual agreements with the respective companies to ensure the data is not used as training material. P8 said, "*We also have clear data processing agreements where we explicitly make sure that they do not use any of this data from the platform for other purposes. That's how we protect the input from citizens being used as further training material*." P7 added, "*So today, when a resident on our platform typically posts an idea or submits a survey response or contributes another mechanism that we have, they leave their name, they leave their email address, they leave potentially some demographic information. We don't send those things to the AI. AI is only about summarizing the content that they have written*."

Additionally, transparency and trust are highly voiced as ethical considerations by both developers and public servants. Developers emphasized the importance of referencing functionality in promoting transparency, explaining that it enables public servants to trace the connection between original inputs from residents and the generated summaries. P6 described, "*So we kind of create that transparency to make sure public servants can easily find back what is based on when AI makes a statement. The machine is there, but let's try to use design to make it as easy as possible for humans to understand what the machine does and verify its actions. And that's not as much rocket science AI, but it's a really better user interface that allows for a good user experience*."

Public servants underscored the necessity of being transparent about AI use and making methodologies accessible to the public to facilitate understanding and encourage further participation. P4 commented, "*There are so many disclaimers and so much information about how we are actively using AI. It's not about not telling people. I feel it is important to be upfront about the use of these tools so people feel empowered to use them as well. Our office employs specialized tools, including maps, Excel, and Python, which are used to understand and produce meaningful insights. However, those tools are not accessible to the general public. So, I think we should be transparent about how these tools helped us to understand things. And our methodology should be accessible to everyone else to encourage a more communal, participatory model of data sharing*."

5. Discussions

5.1 Embracing AI tools: The cultural transformation has happened.

The findings indicate that public servants have increasingly embraced AI tools as integral components to streamline administrative tasks and enhance efficiency. More importantly, the efficiency gained from AI-powered tools appears to differ from that achieved through traditional IT adoption: AI tools expedite the collection and processing of citizen input data and extract insights of higher added value (Loi & Spielkamp, 2021). It is about *revolutionizing the process of generating insights from citizen input*. In addition, AI-driven tools have enabled small organizations to expand their capacity, allowing them to "*do more with less*." As a result, AI tools are seen as a potential solution to the resource constraints faced by local governments (Charles et al., 2022).

The integration of these AI technologies reflects a broader cultural transformation within local governments. Traditionally, public service institutions have been characterized by bureaucratic inertia and resistance to change (Savoldelli et al., 2014). However, the current trend of AI adoption suggests a significant departure from these longstanding practices. Public servants are now more inclined to explore and utilize technological innovations that not only enhance operational efficiency but also foster a more participatory form of governance. This shift is indicative of a cultural reorientation toward openness, agility, and a willingness to experiment with novel approaches to citizen engagement (Henk & Nilssen, 2021).

The cultural shift toward embracing AI tools has significant implications for civic engagement initiatives. By automating routine tasks and providing advanced analytical capabilities, these technologies enable public servants to devote more time and resources to strategic decision-making and policy development. This reallocation of efforts has the potential to foster more meaningful and responsive interactions between local governments and their constituents (Androutsopoulou et al., 2019). Furthermore, the adoption of AI tools helps mitigate some of the challenges associated with managing large-scale digital civic engagement, such as information overload and the need for rapid response to public concerns.

5.2 Keep humans in the loop: Human moderation and AI literacy.

The integration of AI tools into civic engagement initiatives within local governments offers remarkable advantages in terms of efficiency, scalability, and data-driven decision-making. However, the findings of this study underscore that the full potential of these technologies can only be realized when human oversight is maintained—a principle encapsulated in the mantra "*keep humans in the loop*" (Alon-Barkat & Busuioc, 2023). This approach not only compensates for the limitations inherent in automated systems but also fosters the development of AI literacy among public servants, ensuring responsible and ethical deployment of technology. According to the interview results, public servants have expressed concerns about the accuracy and accountability of AI tools. While AI sensemaking adeptly analyzes and synthesizes large, complex datasets into actionable insights, the interpretation of these insights within the intricate socio-political landscape of civic engagement requires a depth of contextual understanding that only public servants can provide.

Interview results highlight a concern about a lack of oversight when governments rely on insights created by AI-based tools. Before the development of more recent AI technologies, technical experts still had a greater ability to scrutinize outcomes to some extent (Hagen, 2018). However, the latest AI technology, such as large language models, makes scrutinizing the AI outcomes nearly impossible. Notably, (1) AI outcomes lack logical paths that humans can trace, and (2) AI development involves complex training data and multiple layers of probabilistic sampling—just two of many challenges in evaluating their results (Zhao et al., 2024). Public servants, through their expertise and familiarity with local contexts, can identify potential biases, challenge erroneous conclusions, and ensure that AI-derived insights align with broader governance goals. Thus, keeping humans in the loop transforms AI sensemaking from a purely computational exercise into a collaborative process that enhances both the reliability and relevance of the outcomes (Wang et al., 2020).

Central to this human-AI collaboration is the need for robust AI literacy among public servants. As local governments increasingly adopt sophisticated digital tools, it becomes imperative that those responsible for managing these systems possess a deep understanding of their operational mechanisms and limitations. AI literacy empowers public servants to critically assess the outputs of AI systems, make informed decisions about when and how to intervene, and continuously refine these technologies based on practical, context-specific feedback (Long & Magerko, 2020). This proficiency not only enhances operational efficiency but also promotes a culture of innovation and ethical accountability within local government institutions.

6. Conclusion

This study examined AI features successfully adopted by local governments for civic engagement practice. Those AI features include automatic formatting and summarization, data analysis, and intelligence generation. Our findings suggest that AI tools have enhanced the capacity of small organizations and contributed to cultural shifts in civic engagement by promoting respectful discussion and improving efficiency. However, public servants also highlighted key challenges, such as concerns about the accuracy of AI-generated outcomes, the need for greater AI literacy, and the lack of accountability in AI decision-making.

This study will make several contributions and holds significant potential for advancing both technological innovation and democratic governance. First, exploring the use of AI-enabled civic engagement tools will significantly contribute to the design and improvement of such systems by enhancing AI-driven interactions and addressing ethical concerns. Second, by examining how AI is utilized to deliver public services and engage with citizens and communities, researchers can identify best practices and innovative approaches that enhance the quality, efficiency, and effectiveness of government services. Third, by studying the impact of AI on community participation and decision-making processes, researchers can determine whether these technologies are effectively reaching marginalized populations and amplifying their voices in the policymaking process. Ultimately, investigating the application of AI in local governments for civic engagement can also help identify and mitigate potential risks and challenges associated with these technologies. This includes concerns related to data privacy, algorithmic bias, digital divides, and the erosion of trust in government institutions. In the meantime, by focusing on the organizational level's adoption of AI in delivering public services, this study would make theoretical contributions toward social informatics in terms of social structures, civic engagement, and ethical considerations.

While this interview study served as an exploratory analysis of the understudied phenomenon of AI use in local governments for civic engagement, there are many directions for future work to expand upon the presented findings. For example, future studies can investigate the use of AI in local governments across various regions, countries, or cultural contexts to understand how variations in governance, resources, and public needs influence the adoption of AI. Additionally, it would be beneficial to conduct studies that focus on citizens' experiences and perceptions of AI-based platforms to gain a deeper understanding of trust, accessibility, and usability issues. Based on the ethical considerations in the findings, we suggest that scholars develop ethical frameworks to ensure transparency, trust, and fairness in AI decision-making processes and study the role of policy and governance frameworks in guiding the ethical use of AI in local governments.

The primary limitation of this study is the limited access to relevant and reliable data in local governments. The

interviews were conducted with one or two representatives from each organization due to concerns about low availability and confidentiality. Also, the lack of background information on each organization and the absence of standardized datasets across these local governments make comparative analysis difficult. This study focused on governments that adopted this specific platform, leading to limited generalizability, which may also result in skewed results due to the overrepresentation of more technologically advanced or resource-rich local governments. Moreover, the research only captured a snapshot in time, missing the long-term evolution of AI adoption in local governments and its impacts on civic engagement.

Appendix

Interview questions for platform designers

Background information

- Can you tell me a little about your positions and work at GoVocal? How long have you been with the company? What are your main responsibilities?
- What inspired GoVocal to focus on developing an AI-based platform for public service and community engagement? What do you think about the use of technology for public service? What do you think about community engagement?

Design and development

- Could you describe the process of designing an AI-based platform for public service and community engagement? What stages are involved? How do you initiate the project?
- What specific challenges do you encounter when developing these platforms? How do you address issues related to data privacy, user trust, and inclusivity?
- How do you ensure that the AI-based platform is user-friendly and accessible to a diverse range of users? What considerations are taken into account for different user demographics?

Technical aspects

- What technologies and tools do you typically use in developing these AI platforms? Are there any specific programming languages, frameworks, or software that are particularly important?
- How do you train and test the AI models to ensure they perform effectively in real-world public service scenarios?
- How do you evaluate the performance? How do you handle misinformation, trolling, and other kinds of manipulative language in the design?

Civic engagement

- How do you understand civic engagement in public services? What are the objectives of community engagement for local government? How do you design for those goals and objectives?
- How do you involve other stakeholders in the design and development process (e.g., public servants and citizens)? What methods do you use to gather feedback from those stakeholders?
- How do you design for different communities, especially for those who have immigrants from other countries or people with other linguistic and cultural backgrounds?

Impact and outcomes

- Can you provide examples of successful implementations of GoVocal's AI platforms in public service and community engagement? What were the key factors that contributed to their success?
- How do you evaluate the impact of your AI platforms on the communities they serve? What metrics or indicators do you use?

Ethical considerations

- What ethical considerations do you take into account when designing AI platforms for public service? How do you address potential bias and discrimination in the AI models?
- How does GoVocal ensure fairness, explainability, security, transparency, and accountability in its AI platforms?

Future directions

- What are GoVocal's future plans for developing AI platforms for public service and community engagement? Are there any upcoming projects or new features you are excited about?
- What advancements in AI do you believe will most significantly impact public service and community

engagement in the next five years?

Interview questions for public servants

Background information

- Can you tell me a little about your role within the local government? How long have you been in this position? What are your main responsibilities?
- How long has your government been using GoVocal?
- What's the size of your population in the community?

Adoption and implementation

- What are the motivations for your governments to adopt the GoVocal platform? How did you make the decision? What are the things that you considered in the adoption?
- Can you describe how GoVocal's AI features are integrated into your public service and community engagement efforts? What specific services or initiatives are you using GoVocal for?
- What was the process of implementing GoVocal Like? What steps did you take? Were there any challenges during the implementation?
- How do you train your staff to use GoVocal's AI features? What kind of training or support does GoVocal provide?

Impact on public service and community engagement

- What improvements or changes have you observed in public service delivery since implementing GoVocal? How do you measure the effectiveness of GoVocal in enhancing public services? Can you provide specific examples or metrics?
- How do you understand community engagement in public services? What are the objectives of community engagement for local government? How has GoVocal impacted community engagement in your areas? Are there any notable success stories or positive outcomes? Or what metrics or indicators do you use?
- How do you involve other stakeholders in the decision-making process (e.g., public servants and citizens) about the implementation of GoVocal in local governments? What methods do you use to gather feedback from those stakeholders?

Impact on work and public service

- How has the use of GoVocal's AI features transformed your work as a public servant? Can you provide specific examples of how it has changed your daily tasks or responsibilities?
- What improvements or efficiencies have you noticed since using GoVocal? How has it affected the way you deliver public services?
- How has GoVocal impacted your interactions with the community? Are there any specific instances where GoVocal improved community engagement?

Challenges and solutions

- What challenges have you encountered while using GoVocal's AI features? How have you addressed or overcome these challenges?
- Are there any limitations of the GoVocal platform that you have identified? How do you work around these limitations?
- Have you needed to adapt your work processes to accommodate GoVocal? What changes did you make to your workflow?

User experience and feedback

- How do the residents and community members respond to the AI features of GoVocal? What feedback have you received from the public?
- How do you collect and incorporate feedback from the community about GoVocal's features? Can you give examples of how community feedback has led to changes or improvements?

Ethical and privacy considerations

- What measures do you take to ensure the ethical use of AI in your work? How do you address issues related to data privacy and security?
- How transparent are you with the community about the use of AI in public services? What steps do you take to maintain transparency and build trust?

Future directions

- What future plans do you have for using GoVocal and its AI features in your local government? Are there any new projects or expansions you are considering?
- What advancements or features would you like to see in GoVocal to better serve your needs?

Algorithmic fairness as sociotechnical system: A typology of the information construct.

Submitted: 31 January 2025, Revised: 26 March 2025, Accepted: 21 April 2025, Published: 19 May 2025

Abstract. Organizations and enterprises search for ways to exploit the vast amount of data that is produced by citizens, sensors, devices and administrative processes. Capitalizing on the produced data should be done responsibly by preventing, mitigating and managing undesired side effects such as violation of rules and regulations, human rights, ethical principles as well as privacy and security requirements. A key challenge in employing data, algorithms and data-driven systems is to adhere to the principle of fairness and justice. In this contribution we focus on the issue of algorithmic fairness, which itself can be framed as a sociotechnical system with interacting social and technical/formal subsystems. Information is a key construct of any sociotechnical system, where information creation and exchange can ease the opacity of interactions between the social and formal subsystems, and of interactions between the subsystems and the environment in which they operate. Based on literature, we categorize the types and flows of the information construct within the sociotechnical systems of algorithmic fairness in 7 categories. As such, the presented insights about the 7 categories of the information construct can form a common mental model whereby social and technical disciplines can inform each other systematically and align their views on algorithmic fairness.

Keywords. Algorithmic fairness, fairness, information construct, justice, sociotechnical systems.
Research paper, DOI: https://doi.org/10.59490/dgo.2025.952

1. Introduction

Data are currently being generated, collected, analyzed, and distributed at a fast-growing pace. This growth is due to proliferation of connected devices (such as cameras, smartphones, sensors, and smart household appliances), widespread and intensive use of social networks, and fast-paced digitalization of business and organizational processes/services, among others. Public organizations and private enterprises collect a vast amount of data directly as a necessary input for provisioning their services or as a byproduct of their services. As a result of this growth, there is a rising interest (and demand) to harvest the available data by using Artificial Intelligence (AI) and Machine Learning (ML) algorithms to develop advanced data-driven systems, like decision-support systems, that ease our daily lives, create additional value for businesses, provide insight into societal phenomena, and guide policymaking processes. These data-driven systems are applied to various domains of society like justice, healthcare, education, public safety and security, public administration, transportation and logistics. Specifically within public organizations, AI and ML have gained a foothold in daily

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

practice for policy making (e.g., to detect social issues quickly, improve policy decisions, and monitor policy implementation), for provisioning public services (e.g., to improve service delivery and develop innovative services), and for managing internal affairs (e.g., to develop management innovations, human resources, procurement and finances), to name a few (Leeuw, 2025). All these have presently resulted in various forms of smart environment paradigms like smart cities, smart healthcare, smart logistics, and smart government.

The current trend of digitization, digitalization and digital transformation worldwide, which relies on digital technology and data-driven systems, has a huge impact on several aspects of our lives. In addition to its potentials, this trend inflicts a wide range of disorders and problems, ranging from sustainability-oriented ones to efficiency-oriented ones (Toli & Murtagh, 2020). Sustainability-oriented problems are related to social values (e.g., equity, community autonomy, citizen well-being, quality of life and gratification of fundamental human needs), economy vitality and diversity, and environment conservation (e.g., flora, fauna, and natural resources). Efficiency-oriented problems are related to efficient management of public and commercial services in various domains of society.

However, as data and data-driven systems are transforming our society on every scale, the so-called smart systems that capitalize on data should not be perceived as pure technological systems. The way that data are collected, which are often blended with sensitive and stigmatizing information about individuals, groups, and businesses, and the way that algorithms and data-driven smart systems are devised, designed, implemented, deployed, and (mis)used (are going to) impact us deeply at individual, group and societal levels. As such, all societal, environmental, technological transformations affected by or derived from data-driven systems must be attentive and respectful of legal, ethical and human rights principles.

Despite the success that data-driven smart systems are experiencing, there are still many key stumbling blocks in their large-scale and real-life deployments. Realizing smart systems, on the one hand, entails several technological challenges like establishing efficient mechanisms for integration, storage, and retrieval of (large volumes of) data, and processing (different types of) data in almost real-time. On the other hand, there are many non-functional challenges for using data and algorithms in practice, also known as soft challenges. Some examples of these challenges are mitigating the security issues of largely distributed data-reliant systems, managing the quality issues of loosely coupled data sources, and dealing with biased and/or wrongful discrimination of individuals and groups (i.e., unfairness) as embedded in collected data or induced due to inattentive design or use of algorithms. Not handling these soft challenges appropriately and adequately would harm individuals, groups and society, adversely affecting basic human rights like privacy, liberty, autonomy and dignity.

In this contribution, we consider decision-support systems, which are a specific case of data-driven smart systems. Often in such systems, AI and ML algorithms are used to train classification models, the trained models are used to predict some outcomes, and the predicted outcomes are used as (partial) evidence for making decisions about individuals (e.g., in credit granting) and/or groups (e.g., in policy-making). A publication by the European Union (EU) office (see Misuraca & van Noordt, 2020) has extensively analyzed the landscape of AI usage in public services across Europe. During the period of May 2019 – February 2020, the report gives an account of 230 initiatives for using AI in public services across Europe. Of these 230 initiatives, there are 29 initiatives (about 13%) categorized as "Expert and Rule-based Systems, Algorithmic Decision Making", which can give a good estimate of the mentioned AI/ML based-decision support-systems for public services. A well known example of such systems in the justice domain is the Correctional Offender Management Profiling for Alternative Sanctions (COMPAS) tool. The tool was used for measuring the risk of a defender to recommit crime, i.e., recidivism. Although the tool was designed to be fair from some perspective (Dieterich et al., 2016), a follow up study showed that the COMPAS tool was unfair from another perspective (Larson et al., 2016). Specifically, African American defendants were more likely than Caucasian defendants to be incorrectly flagged as higher risk of recidivism (false positive rate), while Caucasian defendants were more likely than African American defendants to be incorrectly flagged as low risk of recidivism (false negative rate). Note the results of this paper can be applied to other usage areas of algorithms.

As the outcome of such decision-support systems can be biased against social groups and individuals unjustifiably (Choenni et al., 2018; Dolata et al., 2022; Netten et al., 2018; Starke et al., 2022), we aim at addressing the soft-challenge of social biases and wrongful discrimination (i.e., unfairness) when realizing and using data-driven decision-support systems. This unfairness stems from, for example, the biased data used for training algorithms, the bias introduced in such algorithms, and/or the way that the outcomes are interpreted and applied to the practice (Choenni et al., 2021). In other words, we focus on the field of *algorithmic fairness* which

aims at addressing these biases and discrimination when the outcomes of an AI/ML algorithm is used within (i.e., as a part of) social service provisioning. Not only are decision-support systems used within social services sociotechnical systems, but also their algorithmic fairness component can be regarded as a sociotechnical system with two interacting subsystems: a formal/technical subsystem and a social subsystem (Dolata et al., 2022). Sociotechnical systems are generally characterized by some generic constructs in literature. Information is one of these constructs that shapes and is shaped by how the components of a sociotechnical systems interact and it paves the way to achieve the desired goals of a system by providing some sort of order (i.e., by reducing uncertainty/entropy via imparting dialog, meaning, and utility to sociotechnical interactions) (Chatterjee et al., 2021). Towards the research objective described above, we deliver the following contributions in this paper.

- We present a model of the sociotechnical systems corresponding to algorithmic fairness, which conceptualizes the development stages of these systems. The model encompasses fairness conceptualization, design, and operation stages, where each of these stages has footholds in both technical and social subsystems.
- We delve into the information construct of sociotechnical systems and, based on literature, identify and specify 7 information artifacts that may arise due to interactions among the components of the sociotechnical systems associated with algorithmic fairness.

For this study we have conducted extensive content analysis of the literature to derive the insights and the model presented. The conducted literature review can be characterized as a theoretical review that "draws on existing conceptual and empirical studies to provide a context for identifying, describing, and transforming into a higher order of theoretical structure and various concepts, constructs or relationships" (Paré et al., 2015). Our primary goal was to develop a conceptual model that explains the existing structure and the information construct of algorithmic fairness. To this end, we studied and analyzed a number of selected papers that have been published in leading journals and conferences in fields of data science, law, and ethics. The analysis is performed through the lens of applying AI/ML classification outcomes to social context where, due to uncertainty, the impact on individuals and social groups can be unfair and can thus lead to (social) injustice.

The outline of the paper is follows. In Section 2 we provide some background information about algorithmic fairness and present our conceptual model of algorithmic fairness sociotechnical systems. In Section 3 we review the related literature. In Section 4, we present our typology of the information construct for algorithmic fairness, supported by evidences from the literature. Finally, in Section 5 we discuss the results, draw our conclusions, and mention several directions for future research.

2. Algorithmic fairness as a sociotechnical system

In this section we provide some background information and present our first contribution. We start with explaining relevant concepts in Section 2.1. In Section 2.2 we explain the social and formal views on fairness and algorithmic fairness, as well as their pitfalls. Subsequently, in Sections 2.3 and 2.4 we explain the need for adopting a sociotechnical viewpoint and approach, respectively, to address the issues of algorithmic fairness in complex social settings. In Section 2.5, we summarize the outcome of the section.

2.1. Fairness and algorithmic fairness

Fairness in the context of decision-making refers to the "absence of any prejudice or favoritism toward an individual or group based on their inherent or acquired characteristics" (Mehrabi et al., 2021). Two sources of unfairness (lack of fairness) are bias and wrongful discrimination. (NB., from this point on we will use the term discrimination instead of wrongful discrimination for brevity as well as for conformity to the literature.) In data-driven decision support systems bias can exist in data, algorithms, and/or the way that the outcomes of algorithms are applied to practice (i.e., in interaction between algorithms and users), see (Mehrabi et al., 2021). Some forms of bias can lead to unfairness in different down-stream systems that use the outcomes of data-driven decision support systems. Discrimination is attributed to human prejudice and stereotyping that is based on the sensitive attributes (like gender, race and religion).

Algorithmic fairness refers to those technological solutions that are devised for detecting and preventing systematic harms or benefits to different subgroups and individuals in data-driven decision-making (Dolata et al.,

2022). In other words, algorithmic fairness aims at (a) mathematically quantifying biases in AI and ML based systems using various metrics (or indicators) and (b) devising measures (i.e., solutions) to mitigate unjustified biases and discrimination. We note that protecting both individuals and subgroups is at the focus of such solutions. Further, as will be explained in the following sections, the scope of algorithmic fairness spans beyond technical solutions and intertwines with social solutions (i.e., social measures or interventions) for mitigating undesired biases and discrimination in AI and ML based systems. Therefore, we use *algorithmic-based fairness* to refer to those technical and non-technical solutions in data-driven decision-making processes that can be devised for preventing systematic harms or benefits to individuals or different subgroups (one may refer to this holistic view as algorithmic justice).

Note that algorithmic fairness together with algorithmic transparency (and the related concepts of explainability and interpretability) and cybersecurity (which includes privacy protection) constitute the core components of the field of responsible AI (Chorąś et al., 2020).

2.2. Social and formal views on (algorithmic) fairness

Figure 1 shows our model of the sociotechnical systems corresponding to algorithmic fairness. It actually conceptualizes the development stages of these systems vertically; and the technical and social subsystems of sociotechnical systems horizontally. Conceptually, as shown by conceptualization space in Figure 1, there are two main views on fairness that originate from the social discourse and formal discourse on fairness (see Starke et al., 2022 and Dolata et al., 2022). The social view on fairness can be traced back to disciplines like philosophy, political science, legal science, organization science, criminology, sociology, anthropology, neuroscience, and psychology. The formal view on fairness encompasses attempts to model (aspects of) the social concepts of fairness, especially those borrowed from anthropological and organizational viewpoints. To this end, based on the derived models, one builds formal (i.e., technical) fairness measures and mechanisms in Information System (ISs). While the social discourse inspires the formal discourse (see the link drawn in Figure 1) – thus resulting in mathematical or formal definitions of fairness or the so-called fairness metrics – the formal discourse lays down the ground for the formal aspects of algorithmic fairness.

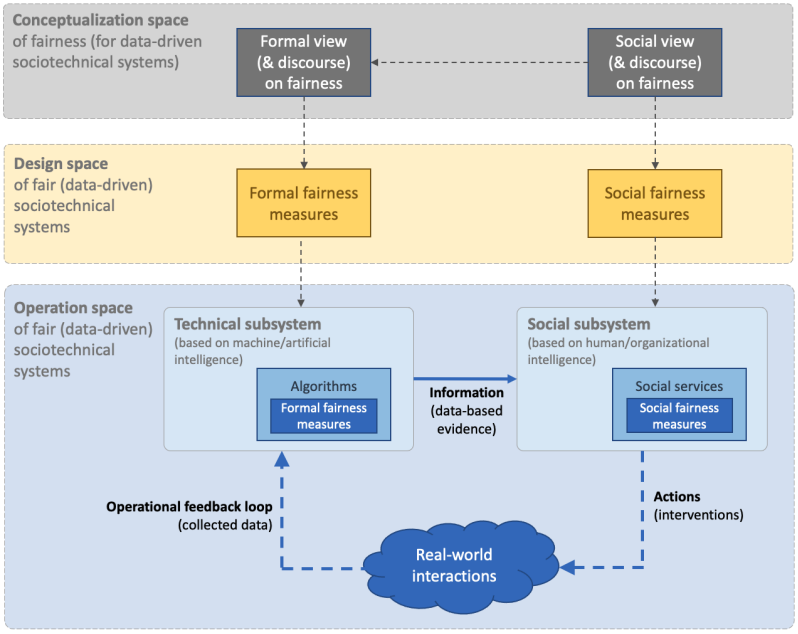

Fig. 1 – An illustration of social and formal aspects of algorithmic fairness in three system development spaces.

In practice, the design space of algorithmic fairness encompasses technical metrics as well as both formal and social measures (solutions), as indicated in the middle of Figure 1. Through design, the formal and social measures of fairness should be combined appropriately to deliver algorithmic-based fairness in a given context. In the operation phase of a data-driven decision support system, as indicated by operation space in Figure 1, the formal and social subsystems, which include formal and social fairness measures, are applied into practice to operationalize the intended intervention. Depending on the operation context, the operation space may encompass group related actions (e.g., making policies) and/or individual related actions (making decisions

about someone). Through interacting with the real-world phenomena and environment, the interaction between technical and social subsystems may lead to emerging behaviors that were not foreseen in the design phase.

2.3. Algorithmic fairness as a sociotechnical system

Investigating algorithmic fairness solutions from the literature, the authors of (Dolata et al., 2022) identify several wrong assumptions that are typically made about algorithmic fairness within the social and formal discourses. For example, in the social discourse one may ignore the differences among various formal fairness measures and treat them equally and/or assume that only human reasoning yields fair decision making (i.e., the so-called black box and purity assumptions). Similarly, in the formal discourse one may assume that there is a technical solution that captures all complex notions of fairness completely (i.e., the so-called equivalence and translation assumptions). Although these assumptions might be stereotypical to some degrees, we think reviewing them is useful for informing about and preventing the possible pitfalls of algorithmic fairness. We argue that system designers may cause harm if they either totally ignore or naively adopt the existing formal solutions.

Each of the social and formal views on fairness puts forward several, to some degree, valid points about algorithm fairness. Nevertheless, there are also interactions between social and formal aspects (and both with environment) that should be considered. In other words, not only is the data driven decision support system a sociotechnical system, so is the algorithmic fairness (aspect of the) system (Dolata et al., 2022). One can characterize algorithmic fairness as a sociotechnical phenomenon because, as illustrated in Figure 1, the process of algorithm design and development is a social practice, since the outcomes of algorithms impact individuals, groups, and society; and algorithms and algorithmic fairness are a matter of public debate (Dolata et al., 2022). As such, the social and formal aspects of algorithmic fairness interact directly or indirectly (i.e., via feedback loops as shown in Figure 1). Further, we note that the nature of these interactions is dynamic and changes in time due to gradual impacts of the interventions triggered by the models, which are a result of the algorithms. Part of this dynamicity can be attributed to the changes that occur in the environment in which the algorithms are deployed due to, for example, introducing new policies, laws, and technologies.

2.4. Adopting a sociotechnical approach

Looking at formal and social aspects individually and optimizing fairness in the formal or social domain separately does not consider the existing interactions and inter-dependencies between them nor does it account for the emerging interactions among social, formal and environmental factors. These interactions and inter-dependencies could be noticed and dealt with if one would consider them together. As the overall outcome of the sociotechnical system should be fair, unfairness threats must be sought in the combined system (like undesired emerging behavior when the formal and social subsystems interact with each other and with the environment). A careful consideration, analysis, or design of machine and human collaborations and engagements in a sociotechnical system relies on the following constructs (Chatterjee et al., 2021; Lee, 2004; Sarker et al., 2019):

- having social and formal subsystems,
- having reciprocal interactions between the social and formal subsystems (and the environment), and
- information arising from the interaction between social and formal subsystems.

In this paper, as to be explained in the following section, we contribute to the basic construct of information within the sociotechnical system of algorithmic fairness (i.e., the last construct mentioned above). The *information* construct is not a subsystem but an emergent property of the overall system that shapes and is shaped by how its social and technical subsystems interact (Chatterjee et al., 2021). "[T]he role of information is to help realize the path (by being well-formed and meaningful) of achieving the desired goals of a system. In other words, information provides some sort of order to a goal-seeking system in its effort to realize those goals, thus reducing entropy" via imparting dialog, meaning, and utility to sociotechnical interactions (Chatterjee et al., 2021). Thus, creating and exchanging information in a well-formed, meaningful, and order-giving way, is a key element/construct of sociotechnical systems. Through contributing to the basic construct of information exchange for the sociotechnical system of algorithmic fairness, we intend to move one step away from the traditional formal notion of algorithmic fairness toward the *sociotechnical* notion of fairness (or *algorithmic based fairness* as we defined in Section 2.1).

2.5. Recapturing on the proposed (mental) model

The model shown in Figure 1 is the a conceptual mental model of the sociotechnical systems associated with algorithmic fairness that we introduce in this contribution. The model aims at conceptualizing the development stages of these systems in three layers (or spaces) of fairness conceptualization, fairness design, and fair algorithm operation. The proposed model of the sociotechnical system of algorithmic fairness captures also the footholds of these stages in both technical and social subsystems.

3. Related work

Algorithmic fairness is complex as it encompasses social and formal components as well as interactions between them and the environment. There is a lot of literature describing the complex landscape of algorithmic fairness from various perspectives. Although there are valuable contributions to various aspects of algorithmic fairness, there is still room to provide more in depth understanding about how these aspects influence each other and how the disciplines involved can inform each other about the characteristics (e.g., capabilities and limitations) of fairness concepts and notions in their fields. In brief, an overarching and unifying framework for algorithmic fairness that streamlines the different perspectives and disciplines is missing.

A lot of the literature emphasizes the need for adopting a cross-disciplinary approach, particularly from a sociotechnical perspective. The authors of (Altman et al., 2018) argue that for algorithmic fairness one should consider the foreseeable effects or harms that algorithmic design, implementation, and use have on the well-being of individuals. They propose a harm-reduction framework for algorithmic fairness, which aims at identifying and mitigating harms during all stages of data lifecycle. Based on a systematic literature review, Starke et al. (Starke et al., 2022) argue about the necessity of a human-centric approach that takes individuals' perceptions on fairness into account when designing and implementing algorithmic decision-making systems. They advocate for more interdisciplinary research that adopts a society-in-the-loop framework. Dolata et al. (Dolata et al., 2022) argue that since fairness is an inherently social concept, using algorithmic fairness technologies should be based on a sociotechnical approach. They aim at embedding algorithmic fairness in the sociotechnical view of ISs and call for undertaking a holistic approach to algorithmic fairness. We build on these ideas behind the sociotechnical approach for algorithmic fairness and aim at providing a systemic view on algorithmic fairness and an informative overview of the main information flows within that systemic view.

4. A typology of the information construct for algorithmic fairness

Realizing an effective sociotechnical approach to algorithmic fairness requires, among others, information harvesting and exchange across the formal and social disciplines involved. In addition to creating transparency, the basic construct of information for sociotechnical systems, as mentioned in Section 2.2, can impart meaning and utility to sociotechnical interactions, can ensure alignment of the social and formal subsystems, and thereby can play a major role in realizing the overall goals of the system. Providing appropriate information about, for example, system components, their dynamic interactions, and the emerging behaviors, can reduce randomness and uncertainty when realizing and operationalizing the system. According to (Beynon-Davies & Wang, 2019), reducing entropy (or in other words uncertainty) is a unifying conception of information that can be related to environmental structures, organization of signals, coding and decoding of signals, shared intentionality of actors, and coordination of joint actions.

Based on literature we distinguish several flows and types of the information construct that may arise due to the interactions between the components of the sociotechnical system of algorithmic fairness shown in Figure 1. The resulting information types and flows are shown in Figure 2, which are inspired by various papers that contribute to each or a subset of therein identified elements. Without intending to be exhaustive, we motivate these information flows/types by reviewing a couple of example works per flow/type shortly in the following.

4.1. Informing about social justice norms

As illustrated by link (a) in Figure 2, the social view informs the formal discourse about social justice and fairness norms. As a result, social view inspires formal view on (aspects of) fairness. The social definitions of fairness originate from various disciplines like philosophy, political science, legal science, criminology, sociology, anthropology, neuroscience, and psychology (Dolata et al., 2022). In (Binns, 2018) the author explains

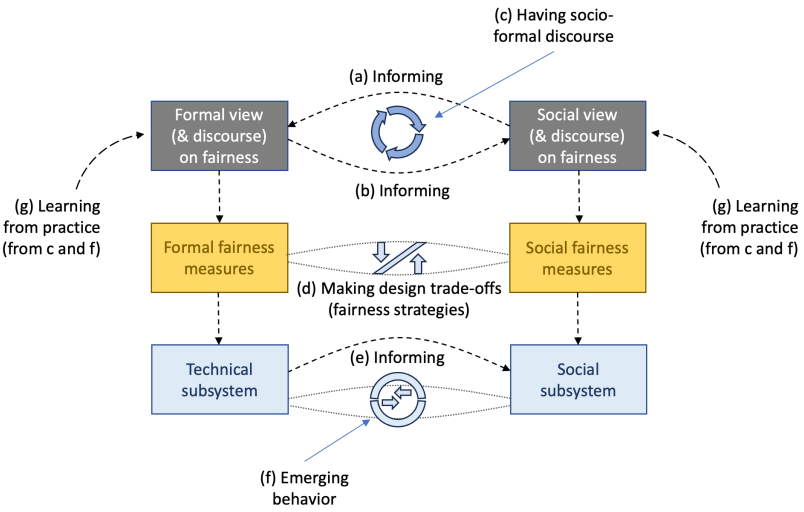

Fig. 2 – An illustration of the informational interactions between social and formal aspects of algorithmic fairness at three levels, which forms the information construct.

the terms fairness and non-discrimination as have been laid down by moral and political philosophers. Binns aims at providing a rigorous understanding about these concepts from political philosophy and elucidating the emerging debates about fair algorithms. This work can be regarded as a typical example of information link (a) shown in Figure 2.

It appears that there are inherent trade-offs between some formal metrics that quantify group and individual fairness. In (Dwork et al., 2012) the authors raise the concern that simple statistical parity metrics between protected groups could be intuitively unfair at the individual level. (In several examples they show the outcome is blatantly unfair for individuals, while statistical parity is maintained for the group the individuals belong.) The work marks another example for information link (a) in Figure 2.

4.2. Informing about algorithmic fairness measures

As illustrated by link (b) in Figure 2, the formal view uses data, simulation and formalism to quantitatively inform the social discourse about some aspects of social fairness (and justice) norms. Often inspired by social definitions of social biases, IS developers define and realize technical measures, i.e., the so-called algorithmic fairness solutions, to deal with the biases, especially when using algorithms in social domains. Existing technical definitions or measures of social bias are of four types: statistical-based, similarity-based, performance-based, and causal reasoning-based (Starke et al., 2022). In practice, there are often discrepancies between the fairness definition(s) as realized in the technical domain, i.e., those offered by algorithmic fairness solutions, and the fairness definition(s) as desired in non-technical domains. In addition to discrepancies between technical and non-technical definitions of fairness, there are discrepancies between the ways that algorithmic fairness solutions are viewed in the technical domain and in non-technical domains. Both sorts of discrepancies (i.e., those between fairness definitions and between views on algorithmic fairness) can contribute to unjustified discrimination of social groups and individuals, especially when applying the outcomes of decision-support systems into practice in social contexts (i.e., where humans, social groups and society are affected directly or indirectly).

To elaborate further on information flow (b), we explain a well-known inconsistency issue among three statistical measures, which is identified in the literature using formal and analytical methods. Specifically, the inconsistency is concerned with statistical measures, on the one hand, the Positive Predictive Value (PPV) and, on the other hand, the False Negative Ratio (FNR) and False Positive Ratio (FPR). Chouldechova (Chouldechova, 2017) gives an analysis of the relation between the PPV, FNR and FPR, assuming that the base rate for protected and unprotected groups differ. Base rate, also called prevalence or prior probability, is the percentage of a social group (like men or women) in a dataset used for training a ML model. Assuming that the base rates for the protected group and the unprotected group are different implies that it is impossible to make both PPV and FNR/FPR the same for both sensitive groups (Chouldechova, 2017). This inconsistency necessitates making trade-offs if and when applying them together into practice is required.

These achievability conditions are also derived in (Kleinberg et al., 2016) in a different and more generic

setting. Both results of (Chouldechova, 2017) and (Kleinberg et al., 2016) show the need for making trade-offs between false positive (idem, false negative) ratios vs predicted parity (or well-calibration in the generic case of Kleinberg et al., 2016). The arguments of (Chouldechova, 2017) and (Kleinberg et al., 2016) are important in investigating the famous COMPAS like cases, where the critique focused on the violation of the false positive (idem, false negative) ratios and the counterarguments established the satisfaction of predictive parity (and well-calibration) condition, see (Corbett-Davies et al., 2016; Flores et al., 2016).

It is important to realize that these results, which are derived with formal methods (and data analytics), hold for all decision-makings; including those made by human decision makers who carry out structured decision rules (Corbett-Davies et al., 2016).

4.3. Information derived from socio-formal discourse

As illustrated by link (c) in Figure 2, the exchange of information flows (a) and (b) paves the way for a socio-formal discourse, which leads to enriching the social and/or formal concepts of fairness.

In (Binns, 2020), the author reconsiders the conflict or inconsistency between group and individual fairness metrics as was already raised in (Dwork et al., 2012). This conflict exists in cases where two similar individuals who belong to different social groups (i.e., they are otherwise similar but differ in a protected characteristic) are assigned different outcomes in order to satisfy group fairness. In this case group fairness leads to individual unfairness. The authors of (Binns, 2020) argue that the conflict is a misconception based on theoretical discussions from formal and social discourses. As a result, the paper concludes that individual and group fairness are not fundamentally in conflict and that "the apparent conflict ... is more of an artefact of the blunt application of fairness measures, rather than a matter of conflicting principles". Similarly, in (Hellman, 2020) the author reconsiders the legal and philosophical rationale behind the fairness metrics that are shown to be in conflict in the case of the COMPAS tool. Both papers (Binns, 2020) and (Hellman, 2020) can be seen as a testimony of the information creation shown by link (c) in Figure 2.

4.4. Information about design trade-offs

The link (d) in Figure 2 represents the information (e.g., the design guidelines) needed for dealing with the inconsistencies that might exist among formal (and social) fairness metrics and/or measures. In the design space, this information is needed for making trade offs within and between contending social and formal fairness measures (i.e., among the partial solutions of the algorithmic-based fairness).

Both results of (Chouldechova, 2017) and (Kleinberg et al., 2016) show the need for making trade-offs between the contending statistical measures of PPV, FNR and FPR, as mentioned for link (b). The author in (Chouldechova, 2017) propose three strategies for making such trade-offs namely:

- "Allow unequal false negative rates to retain equal PPV's and achieve equal false positive rates,
- Allow unequal false positive rates to retain equal PPV's and achieve equal false negative rates,
- Allow unequal PPV's to achieve equal false positive and false negative rates".

Other options that in theory might work would be making perfect prediction (i.e., making FPR and FNR) zero (or negligible) for both protected and unprotected groups) or making the base rates for social groups equal. Although the last two options are impractical, but they could be seen as a justification of striving for perfect solutions (like eradication of social inequalities).

The trade-offs can not only be made between technical algorithmic measures as mentioned above, but also between technical and social and/or less technical ones. For the latter category one can think of trending solutions of algorithmic recourse (Karimi et al., 2022) and algorithmic contestability (Alfrink et al., 2023). Algorithmic recourse is concerned with providing explanations and recommendations to individuals who have received unfavorable outcomes from automatic decision-making systems. The explanations and recommendations should provide end-users with actionable measures whereby the outcome of an AI system can be changed to the favorable one. Making AI systems contestable by design is another way to mitigate these concerns. Via algorithmic contestability one aims at making AI systems responsive to human intervention throughout the system lifecycle. Such a human intervention can ask an AI system, for example, to explain and

interpret how outcomes are derived (including, from which input and training data). Unlike in algorithmic recourse, in algorithmic contestability the objective is not to change the algorithm outcome, but to change the outcome of the whole process from which the algorithm is part of (i.e., the term algorithmic-based fairness we introduced above). Answering these questions in both algorithmic recourse and algorithmic contestability can be facilitated by having data lineage in place (Bargh, 2024).

These works can be seen as examples for link (d) in Figure 2, representing the information (or guidelines) needed for making design trade offs among various formal metrics and social interventions.

4.5. Information about the applied fairness measures

As illustrated by link (e) in Figure 2, during system operation phase, there is a need for the AI/ML system to explain and inform social domain about the meaning and certainty of the outcomes of the technical subsystem. This information may help social domain practitioners to interpret the outcomes appropriately within the operation context.

Several works give overviews about the formal (i.e., technical) metrics and measures to algorithmic fairness from different perspectives, which can be characterized as examples of information flows and types denoted by link (e) - and to some degree of types (a) and (b) - in Figure 2. In (Verma & Rubin, 2018; Zafar et al., 2017) the authors present statistical fairness metrics according to three fairness notions of disparate treatment, disparate impact and disparate mistreatment. (Note that the scope of technical solutions covered in Verma & Rubin, 2018 is broader than statistical fairness metrics.) Carey and Wu (Carey & Wu, 2023) survey statistical fairness metrics and explain the philosophical views on fairness (like equality of opportunity and luck-egalitarian) that support or inspire those metrics.

Similarly, Verma and Rubin (Verma & Rubin, 2018) provide an overview of the most prominent formal metrics and measures of fairness which can be applicable for the algorithmic classification problem. Further, they elaborate on inconsistencies among these definitions. Balayn et al. (Balayn et al., 2021) and Mehrabi et al. (Mehrabi et al., 2021) survey the literature about bias and unfairness, the metrics and methods to identify these biases, and the measures to deal with these biases. While the former focuses on bias in training data (thus on fairness metrics, fairness identification, and unfairness mitigation methods in the field of data management), the latter considers these aspects also within algorithms and at the interaction point between end-users and algorithms.

4.6. Information about unforeseen behavior

As illustrated by link (f) in Figure 2, due to interactions of the technical and social subsystems in the operation phase, a new behavior may emerge that was not known beforehand (i.e., during the conceptualization and design phases). This emerging behavior should be accounted for and documented for further use.

Considering the feedback loops shown in Figure 1, context dependency, and the growing use of AI algorithms, algorithmic fairness sociotechnical systems can be perceived as complex systems. Scholars consider the notion of complex systems versus simple systems, although the boundary between them cannot be identified precisely (Manning & Ravi, 2013). In narrative terms, complex systems encompass, among others, contextuality, reflexivity, temporal sensitivity; allowing for reproduction, self-organization, and adaptation. In such systems, interaction among localized mechanisms within sybsystems may cause undesired emergent (mis)behaviors at a more aggregated scale (Manning & Ravi, 2013; Mogul, 2006).

When an algorithmic fairness solution is designed and implemented, there might arise new insights that were not foreseen beforehand during conceptualization or design phases. A testimonial example for this is the COMPAS tool. As mentioned in the previous sections, the tool was designed to be fair from the viewpoint of some formal fairness metrics (Dieterich et al., 2016) but, as shown by a follow up study (Larson et al., 2016), the tool was unfair according to another metric. This case can be seen as an example of link (f) shown in Figure 2.

4.7. Informing formal and social definitions

As illustrated by link (g) in Figure 2, the emerging behavior can be used for enriching social and formal views and their discourse. Current research communities are predominantly reactive in addressing the emerging "issues" from the growing use of algorithms in society. Therefore, there is an urgent need for the unity of intellectual frameworks beyond disciplinary perspectives and research practices, to offer holistic thought leadership in this space (Engin et al., 2024). A key aspect of this holistic approach is to learn from and adopt to the emerging (mis)behaviors from the practice. To this end, a realistic (impact) evaluation of such systems, which is lacking nowadays, is needed before, during and after their operation (Leeuw, 2025). The outcomes of such learning can be used to enrich the conceptualization and design of algorithmic fairness.

One of the concepts close to fairness that has changed during the time is privacy (Bargh, 2019). As the early principled discussion of privacy, Aristotle made distinction between public and private spheres of life (Nissim & Wood, 2018). Afterwards, there have been many definitions for privacy introduced, particularly within legal regimes like the right to be let alone by Warren and Brandeis in 1890, limited access to the self by Godkin in 1880, and control over personal information by Westin (Westin, 1968). An interesting point within the evolution of privacy concept is the role or rise of certain technological developments. The definition of Warren and Brandeis, i.e., the right to be let alone, brought up as a reaction to Kodak's new snap cameras and widespread newspaper circulation in 1890's. Later on, we notice ICT developments which made it possible to transfer data between remote servers (like development of the DARPANET in the 1970's), coincides with Westin's definition in 1968.

5. Conclusion

Despite the success that data-driven decision making systems offer, there are still many obstacles in their large-scale and real-life deployments like mitigating the security issues of largely distributed data-reliant systems, managing the quality issues of loosely coupled data sources, and dealing with social biases and wrongful discrimination of individuals and groups (i.e., unfairness) as embedded in collected data or induced due to inattentive data processing. Not handling these soft challenges appropriately and adequately would harm individuals, groups, and society, adversely affecting basic human rights like privacy, liberty, autonomy, and dignity.

Inspired by non-technical definitions of social biases and discrimination, IS developers define and realize algorithmic fairness solutions to deal with these issues, especially when using AI/ML based algorithms. In practice, there are discrepancies between the ways that algorithmic fairness solutions are viewed in formal and social domains. Such discrepancies can contribute to an inefficient system design, which may lead to to unjustified biases and discrimination of social groups and individuals. Such a practice becomes highly risky, especially when applying the outcomes of decision-support systems in social contexts (i.e., where humans, social groups and society are affected directly or indirectly).

In this contribution we focused on the issue of algorithmic fairness, which, in itself, can be framed as a sociotechnical system with interacting social and formal components. The information construct is considered as a key element of sociotechnical systems. It is concerned with creating and exchanging information in a well-formed, meaningful, and order-giving way. As part of the information construct, we presented a conceptual (mental) model of the sociotechnical systems associated with algorithmic fairness. The model conceptualizes the development stages of these systems for both formal and social views. As such, it can serve as a mental model for both formal and social stakeholders. Having such a common view on the complex algorithmic fairness sociotechnical systems can facilitate information exchange among the multi-disciplinary stakeholders involved and thus help bridging the gap between the formal and social views. In addition, from the literature, we noted that providing information eases the opacity of the components of the algorithmic fairness sociotechnical system. As another contribution, we identified 7 types of the information types and flows, which can collectively constitute the information construct of the sociotechnical system of algorithmic fairness.

In our future research, we will elaborate on the existing inconsistencies among some statistical fairness metrics from the literature, which ask for making tradeoffs among contending values. Further, we will sketch and discuss several strategies to deal with some aspects of algorithmic fairness (like making trade-offs). Despite being developed within or inspired by the formal perspective, we foresee that these strategies can inform the design of integrated formal and social solutions that aim at adhering to fairness principles and ideals.

Abstract. This article introduces the AI4Gov Canvas, an evidence-based framework designed to identify and develop the competences needed by individuals working with artificial intelligence (AI) in the public sector. Recognising the need for functional specialist profiles in AI management, use and implementation within public administrations, we address the challenge of combining a variety of domains, such as technology, management and design, and policy, ethical and legal expertise.

The AI4Gov Canvas was developed through a three-step process of competence identification, clustering, and validation, involving a review of research and grey literature, expert interviews (N=5), and an online survey (N=54). It is structured around three dimensions: technology, management and design, and policy/legal/ethical, with each dimension further categorized into three levels of abstraction: meta-competences, governance competences, and operational competences.

The Canvas serves as a practical tool for mapping existing competences, identifying training needs, and designing functional specialist profiles that balance competence importance with the difficulty of obtaining them. We provide concrete examples of how the Canvas can be used to create personas, such as the "TechnoSteward" and the "Policy Sentinel", which highlight the framework's ability to guide the development of realistic and multi-disciplinary competence profiles. We conclude by outlining lessons learnt and future steps.

Keywords. Artificial intelligence, public sector, competences, governance.

1. Introduction

Artificial intelligence (AI) is becoming an increasingly vital technology for tackling social challenges and improving policymaking and public services. However, to successfully utilise these technologies, public administrations need to have the competences in their workforce to develop AI solutions, manage such initiatives, and ensure that they are used effectively.

The lack of a skilled workforce in AI is one of the critical challenges public administrations face: public managers often have limited expertise and lack competent figures to harness the benefits of AI technologies (Ahn & Chen, 2022; Neumann et al., 2022). While the lack of competencies in public administration plagues the effective deployment of other technologies as well (Zhang & Kimathi, 2022), they become crucial in avoiding irresponsible use of AI that may lead to harm. For instance, working with ethical frameworks requires different ways of working

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

than merely having these frameworks (Fest et al., 2022). Public organisations are in need for functional specialist profiles on AI development and implementation with relevant competences.

Competences encompass key skills, expertise, and knowledge that are essential for various facets of developing and utilizing AI within the public sector. The European Centre for the Development of Vocational Training's defines competences as 'The ability to apply learning outcomes adequately in a defined context (education, work, personal or professional development)' (European Centre for the Development of Vocational Training, 2008, p. 47). This definition also specifies that 'competence is not limited to cognitive elements (involving the use of theory, concepts or tacit knowledge); it also encompasses functional aspects (involving technical skills) as well as interpersonal attributes (e.g. social or organisational skills) and ethical values' (European Centre for the Development of Vocational Training, 2008, p. 47).

Some existing frameworks on competences in a digital society have tackled the need to identify and categorize competences for relevant stakeholders. The Digital competence Framework (DigComp) (Vuorikari et al., 2022), for European citizens, and the Entrepreneurship competence Framework (EntreComp) (Bacigalupo et al., 2016), for enterprises, include general competences needed for personal development, social inclusion, active citizenship and employment, and transversal skills, such as entrepreneurship. While neither specifically focused on the public sector, nor on AI, they have paved the way for the global discourse on the need for identifying, building, and disseminating competences in the workforce of the future.

Researching competences for artificial intelligence (AI) in the public sector differs significantly from studying general digital competences due to the unique challenges and requirements associated with AI adoption in government contexts. AI competences in the public sector extend beyond technical skills, reflecting the need for compliance with regulatory frameworks like the EU AI Act and the broader societal impacts of AI implementation. These competences are also closely tied to governance practices that ensure effective deployment and continuous improvement of AI solutions, which are often hindered by rigid organizational structures and limited resources in public institutions. In contrast, research on general digital competences typically focuses on foundational skills for using digital tools and technologies, which are relevant across sectors but lack the specialized focus on governance, ethics, and public accountability required for AI in government settings (Hofmann & Ogonek, 2018).

The notable framework by the European Commission's Study on the development of a European framework for interoperability skills and competences in the public sector (EIFISC) (European Commission, 2021) is an example of zooming in on general competences related to digital transformation in the public sector. Scholarly studies so far have provided numerous empirical studies on general digitalization competences in the public sector (Edelmann et al., 2023; Hunnius & Schuppan, 2013; Mankevich et al., 2022; Ogonek et al., 2016), for example in relation to public middle managers (Roehl & Crompvoets, 2024), on digital leadership (Roman et al., 2018), and the context of smart cities (Tsoutsa & Lampropoulos, 2022) or developing countries (Hooda & Singla, 2020)

Only recently, the need for a specific framework on AI-related competences in the public sector has started to be discussed. The UNESCO framework "*Artificial Intelligence and Digital Transformation: Competences for Civil Servants* (Broadband Commission, 2022) has built the foundations for an in-depth understanding of the competence profiles of public servants that public organizations need when dealing with AI and is echoed in recent calls for further development of a comprehensive framework with the same focus (Misuraca et al., 2024).

However, key challenges emerge in the definition of an evidence-based framework that can be used as a practical tool for public managers engaged in AI projects. A first challenge rests in combining a large variety of domains that the adoption of AI in the public sector encompasses. These domains include technology expertise, such as software programming and Information Technology (IT) architecture designing; but also include managerial expertise, for example in leading AI teams; domain expertise, for example in combining AI and policy formulation; and ethical and legal expertise, for example in complying with national and supra-national regulatory guidelines (see, for instance, Mergel et al., 2024; Selten & Klievink, 2024; Medaglia et al. 2024).

A second challenge is that a single individual cannot realistically master all needed competences with equal proficiency (Misuraca & Rossel, 2023). The ideal competence profiles needed for individuals dealing with the opportunities and challenges of AI in the public sector are by necessity multi-disciplinary. On the one hand, in fact, public servants that are only knowledgeable on legal compliance practices, policymaking, and project management, for example, are ill-prepared to deal with AI initiatives, because they lack an understanding of the technical inner workings of AI systems and of their affordances. On the other hand, pure technologists who master "hard" skills in system design and programming, for example, lack the necessary insights to capture the value of such technologies in a public service context. While each competence domain is in high demand and essential to avoid common public AI project failures, it is not feasible for a single individual to have equally in-depth knowledge of the many relevant domains simultaneously.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

To address these challenges, in this article we present the AI4Gov Canvas, an evidence-based framework to identify the competences required for a functional specialist in the management, implementation, and use of AI in public sector organizations.

The Canvas stems from the experience of the AI4Gov Master on AI for public services, a training programme co-funded by the European Union (EU) under the Connecting Europe Facility (CEF), designed and implemented to equip public managers with the competences needed to manage AI in the public sector. The Master was first offered in 2021-2022 and was awarded the European Digital Skills Award in the area of Upskilling in 2023.

2. Methodology

To develop a comprehensive framework of competences for the design, implementation, management, and use of AI in the public sector, we employed a three-step approach: competence identification, clustering, and validation. These steps build upon one another to generate a robust framework.

The first step, *competence identification*, aimed to gather relevant competences from existing knowledge on AI in the public sector. This involved a) a review of academic literature identified with a combination of a keyword search in research databases, and of a meta-review of published literature reviews on AI in the public sector (Reis et al., 2019; Sharma et al., 2020; Sousa et al., 2019; Wirtz et al., 2021, 2022; Zuiderwijk et al., 2021), to map competences highlighted in empirical studies (N=15); b) a review of policy and "grey" literature from think tanks, consultancy organizations, and public institutions, carried out through a snowball approach (N=5); and interviews with experts on AI in the public sector (N=5), recruited via the AI4Gov network. The outcome was a list of competences categorized into three dimensions: technology, managerial and design, and policy/legal/ethical competences.

The second step, *competence clustering*, focused on classifying these competences according to different levels of abstraction. Competences in fact range from abstract concepts such as attitudes (e.g., risk proclivity, user centricity) and general knowledge (e.g., foundational AI knowledge), to practical skills like data collection and budgeting. To systematically incorporate this range, the competences were classified into three levels: *meta-competences* (the most abstract), *governance competences*, and *operational competences* (the most practical). To validate and integrate this classification, a workshop with 20 public servants experienced in AI and digitalization in the public sector recruited through the AI4Gov network was held.

The final step, *competence validation*, assessed the relevance and difficulty of obtaining each competence. This step addressed the reality that not all competences are equally important or easy to acquire in practice, nor they are equally difficult to obtain. An online survey of experts among public sector organizations (N=54) was conducted, where participants ranked each competence in terms of perceived relevance and difficulty, using a constant-sum allocation method (Desarbo et al., 1995). The constant-sum allocation method nudged respondents to make mindful choices between survey items, thus avoiding the possibility that all competences are marked as equally important and/or equally difficult to obtain. The method has been fruitfully used in research literature to support the creation of competence frameworks, such as non-technical competences in business degrees and business graduates (Jackson & Chapman, 2012a; 2012b) and the value of smart manufacturing competences (Böhm et al., 2023). Using the Qualtrics software for online surveys, we designed items so that the respondents had to use sliders to allocate a limited number of points across each group of competences, to evaluate each of them in terms of importance, and of difficulty to obtain. The number of points for each group of competences equalled 100 points, times the number of competences in the group that the competence belongs to.

Figure 1 provides an example of how the constant-sum allocation method was presented in the online survey.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

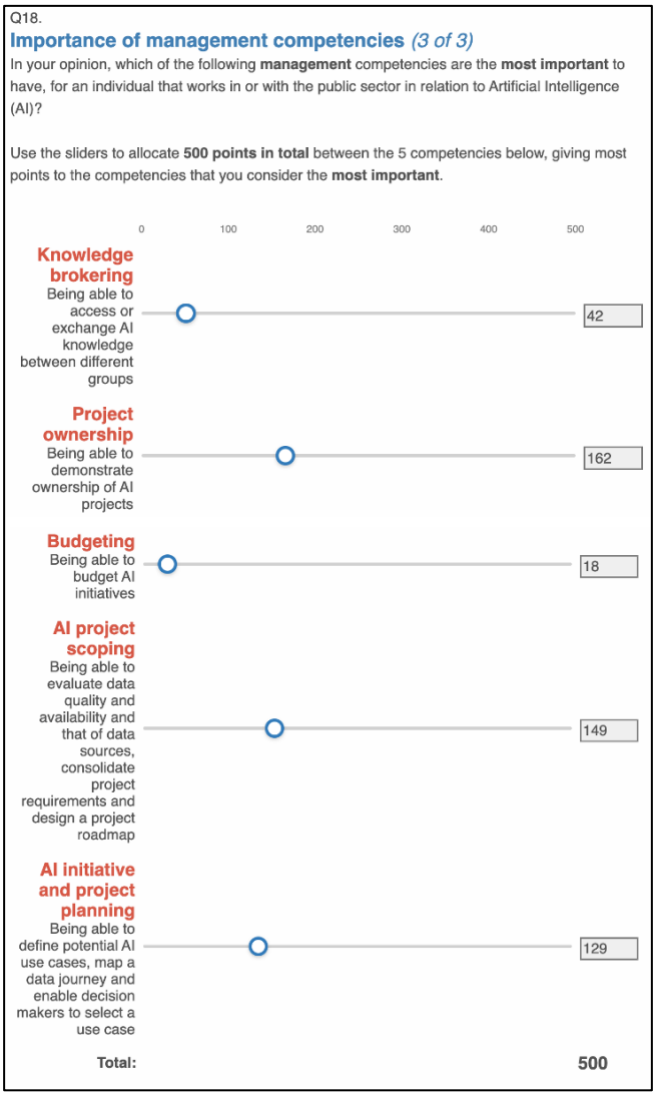

Fig. 1 – Constant-sum allocation method: example of a survey item.

The resulting data allowed us to define trade-offs when designing competence profiles that balance relevance and difficulty. This process ensures that the resulting competence framework reflects the practical constraints and priorities faced by public organizations in developing AI-related skills. As the outcome of this process, we created a comprehensive framework called the *AI4Gov Canvas*. This operational tool can be used by stakeholders to guide the development of AI competences in the public sector.

3. Results

The Annex to this article presents the list of all competences mapped, including a) the groupings in the three dimensions (management and design, technological, and policy, legal, and ethical) and in the three levels of abstraction (meta-competences, governance competences, and operational competences); b) the description of each competence; c) the coefficient of importance and coefficient of difficulty to obtain (μ) of each competence, derived from averaging the results of the online survey.

Results from the technology meta-competence group show that the most important competences are considered the foundational knowledge of AI (average score: 129) and data governance (average score: 124). This highlights the necessity for public sector professionals to have a solid understanding of AI principles and technologies to make informed decisions regarding AI integration. Coincidentally, these two competences are also considered the most difficult to obtain in the group (μ=116 and μ=169, respectively).

On the other hand, "awareness of fairness challenges" garnered an average score of 83, indicating that while respondents recognize the importance of fairness and bias mitigation in AI, they considered this technical competence not as important.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

In comparing these values, it becomes evident that data-related skills and foundational AI knowledge are of paramount importance. While other competences, such as awareness of fairness challenges, technical design, technology inquisitiveness, and cultivating a data-oriented culture, are also valuable, their ranking provides a ground for prioritizing competences in building competence profiles.

It is noteworthy that some competences are considered highly relevant, yet they are also considered relatively easy to obtain. This is the case of "positive attitude towards AI" (μ=44) and "basic data literacy" (μ=78). Such competences are to be kept in mind, as they can be considered relatively "low-hanging fruits" when devising competence profiles for a Functional Specialist of AI in the public sector.

Results from the technology governance competence group show that competences in this group are considered easier to obtain. The most important competence, technical fairness risk mitigation, in fact, features a coefficient of difficulty to obtain very close to the baseline of 100. Other important competences that are considered relatively easy to obtain are "choice of machine learning techniques" (μ=95), and "choice of AI architecture" (μ=105).

Results from the technology operational competence group show that competences related to data collection and data quality assessment are considered the most important ones. Similarly to technology governance competences, these operational competences are also considered relatively easy to obtain. Understanding the fundamentals of machine learning, for instance, features a μ coefficient of 91, while being the third most importance technology operational competence.

Results from the management and design meta-competence group show that problem identification and framing, foresight, and user-centricity are not only the most important competences, but are also considered the hardest to obtain. These competences at a high level of abstraction represent the foundation of this cluster of competences for engaging with AI for public services.

Results from the management and design governance competence group also show that the most important competences are also the ones that are hardest to obtain. Change leadership (μ=118) and risk anticipation and mitigation (μ=116), in fact, feature a coefficient of difficulty to obtain that is well above the baseline. This pattern is also confirmed in the responses on the group of management and design operational competences. Competences that are considered the most important are also the ones that are considered the hardest to obtain. The competence of AI project scoping, for example, is very highly scored in terms of importance (153), and features one of the highest coefficients of difficulty to obtain of the entire list of competences (μ=143). On the other hand, the least important operational management competences of budgeting (μ=90) and of project ownership (μ=73) feature a much lower coefficient.

Results from the policy, legal and ethical meta-competence group show that critical technology assessment is considered the most important (133) and most difficult to obtain (μ=121) of this group of competences at a high level of abstraction. In general, all competences in this group feature a relatively high difficulty to obtain, except for the competence related to dissemination (μ=60).

The policy, legal and ethical governance group includes only four competences. Survey results show that AI procurement literacy is considered the most important competence of this group (108), while AI-compatible formulation is the hardest to obtain (μ=113).

Results from operational competence group in the policy, legal and ethical dimension show that understanding legal and ethical frameworks is considered the most important competence (115). On the other hand, the competence among these operational ones that is most difficult to obtain is specialized legal expertise (μ=121).

The diversity in importance ranking and difficulty in obtaining of each of these competences belonging to different dimensions and different levels of abstraction forms the basis for building a Functional Specialist Canvas. We present this framework in the next section.

4. The AI4Gov Canvas

The AI4Gov Canvas frames all competences identified and refined through the previous steps, clustered in the three dimensions of technology, management and design, and policy / legal / ethical. Each competence is also layered according to a level of abstraction, which increases as one gets closer to the centre: operational, governance, and meta-competence. The Canvas can be used as a spatial device to position each of the competences within the two dimensions of type of competence, and level of abstraction. Additionally, competences can be selected based on the degree of importance, and the coefficient of difficulty to obtain, derived from the results of the survey study. We illustrate an example of a possible use of the Canvas in Figure 2.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

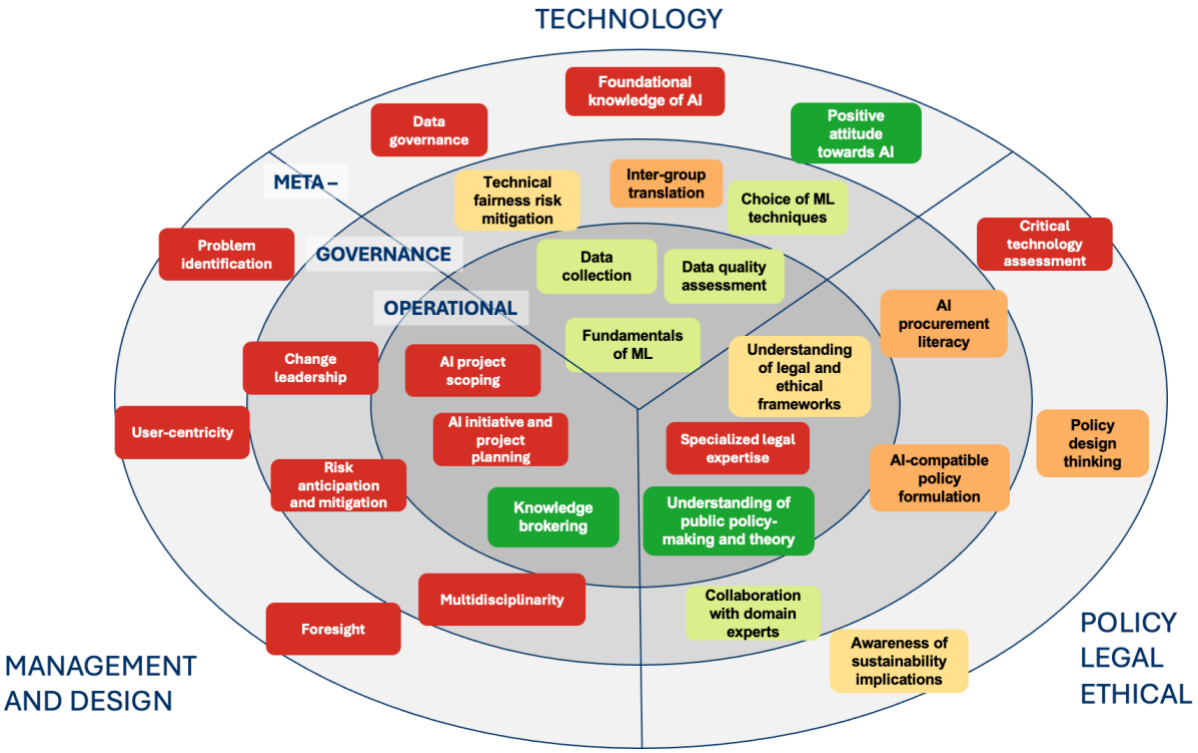

Fig. 2 - An illustration of the use of the AI4Gov Canvas.

In this example, we have mapped the three most important competences for each dimension and for each level of abstraction according to the average relevance score provided in the survey. Moreover, each competence is color-coded according to the average μ coefficient of difficulty obtained from the survey data, from vivid red (most difficult to obtain), to vivid green (least difficult to obtain).

Beyond the provided example, the canvas is developed to serve as a visual, flexible, and generative framework, rather than only a fixed assessment grid. Inspired by design research and public sector innovation practices, the use of the word *canvas* is deliberate and refers to a visual and structured co-design tool that facilitates reflection, discussion, and strategic alignment across stakeholders. The AI4Gov Canvas is not merely a static competence map; it is a generative framework that supports interactive and iterative dialogue about the conditions and capabilities necessary for a public sector organization to meaningfully engage with and govern AI. While existing tools may focus on business models or value creation, the AI4Gov Canvas is unique in its orientation toward public governance and its function as a reflective support for public sector institutions to explore their readiness and responsibilities when engaging with AI. The canvas format serves not only as an evidence-based mapping tool to assess competencies, but to stimulate critical discussion about the type of competence (technology, management and design, and policy /legal / ethical), its level of abstraction, its importance, and its difficulty to obtain. This in turn helps address the socio-technical, organizational, and political dimensions that shape AI governance. The AI4Gov Canvas is thus best understood as a sense-making tool: one that helps public sector teams explore the evolving capabilities they need to responsibly and strategically engage with AI, rather than providing prescriptive answers or benchmarking maturity levels. In this sense, it also provides a handy heuristic for tackling practical challenges in the governance of AI in the public sector.

For instance, the Canvas can be used to map the competences of a public manager, in order to precisely identify their area of strength and weaknesses against multiple dimensions (type of competences, level of abstraction, relevance, and difficulty to obtain). Such assessment can be used for purposes of benchmarking, both at individual and at organizational level of analysis; for rewarding public administration personnel; and for identifying training needs. Moreover, the Canvas can also be used to assess prospective public managers. This is the case of the use of the Canvas as a support tool in hiring processes. Candidates for a position in a public organization dealing with AI projects can be more objectively assessed against the multiple dimensions mentioned above.

Lastly, the Canvas lends itself to a *prescriptive* use. This goes beyond the *descriptive* approach that underpins the use of the Canvas for mapping competences, to include the use of the Canvas as a device to generate desired combinations of competences across multiple dimensions. This use of the Canvas allows for building of Functional Specialist profiles.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

5. Designing functional specialist personas

The structure of the Canvas enables the bounded creation of Functional Specialist profiles. It does so by drawing on both the multiplicity of the dimensions it encompasses (type of competences, and levels of abstraction, relevance, and difficulty to obtain) but also, and most importantly, on the constraints provided by the coefficients associated to each competence.

These constraints are the feature that makes the AI4Gov Canvas stand out, when compared to existing similar competence frameworks – regardless of whether they are focused specifically on AI, or on general digital competences.

By setting a maximum value of both the score of importance and of the coefficient of difficulty to obtain that each competence has, users of the AI4Gov Canvas can better avoid devising lists of competences as mere "wish lists", or "dream profiles" that are not realistic. The AI4Gov Canvas, in fact, forces its users to make the necessary trade-offs between competences, even when devising profiles that are multi-disciplinary.

These trade-offs concern each of the dimensions that form the Canvas. With regards to the dimension of the *type* of competence: even for a functional specialist that is meant to possess competences across the technical, the management and design, and the policy / legal / ethical dimension, in which ones of these should they be stronger? With regards to the dimension of the level of abstraction of competence: should a desired functional specialist have mostly operational, governance, or meta-competences? With regards to the level of importance of each competence: should a desired functional specialist possess one very important competence, and multiple competences of much less importance? Or should they possess the largest possible number of averagely important competences? Finally, with regards to the difficulty of each competence: should a desired functional specialist possess one competence that is very difficult to obtain, and multiple competences that are much easier to obtain? Or should they possess the largest possible number of averagely difficult-to-obtain competences?

The AI4Gov Canvas allows to make informed decisions in devising functional specialist profiles for AI in the public sector. We will now turn to providing some concrete examples of how the Canvas can be used to create Functional Specialist personas.

5.1 Example 1: the TechnoSteward

Table 1 provides the details of an example of a competence profile created using the constraints of the AI4Gov Canvas. This example represents a Functional Specialist persona that features nine competences. In the Table, the competences are distributed across the three dimensions of type of competence (technology, management and design, and policy / legal / ethical) and the three levels of abstraction (operational, governance, and meta-competences) of the Canvas.

	Technology			**Management and design**			**Policy / legal / ethical**			**Total**	
		Imp.	*μ*		*Imp.*	*μ*		*Imp.*	*μ*	*Imp.*	*μ*
Operational	**AI-related software programming**	87	114	Knowledge brokering	89	72	Understanding of public policymaking and theory	97	77	273	263
Governance	**Inter-group translation**	120	113	Cross-team collaboration	101	97	Collaboration with domain experts	98	95	319	305
Meta-	**Data governance**	124	169	Data-supported decision-making	96	76	Dissemination	79	60	299	305
		331	396		286	245		274	232	**891**	**873**

Tab. 1 - Competences of the "TechnoSteward" functional specialist persona.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

In this example, building a Functional Specialist profile corresponds to selecting nine competences that maximise the sum value of the level of importance of all competences combined (indicated as "Imp." in Table 1). Any competence can thus be chosen, with the constraint that the sum of the coefficient of difficulty to obtain (μ) of all the nine competences should not exceed the baseline difficulty to obtain of each competence (μ=100) multiplied by the number of competences in the profile (9 * μ100 = μ900).

The competences for this example profile have been selected within this constraint to include a particular focus on the technology dimension. Therefore, all three competences in the technology dimension have been chosen to have a very high coefficient of difficulty to obtain. These are (highlighted in bold type in Table 1): AI-related software programming (μ=114), inter-group translation (μ=120), and data governance (μ=124).

Conversely, in the other two dimensions (management and design, and policy / legal / ethical dimension), competences with low coefficients of difficulty have necessarily been selected. The three least difficult competences (highlighted in red in Table 9) are, in fact, knowledge brokering, in the management and design dimension (μ=72), and understanding of public policymaking and theory (μ=77) and dissemination (μ=60), in the policy / legal / ethical dimension.

For the rest of the competences, this technology-focused profile provides for selecting desired competences whose sum of the coefficients of difficulty is as close as possible to 900, but without exceeding it (μ=873); and for racking up as much value of importance as possible: in this case, Imp.=891.

Looking at the characteristics of this Functional Specialist competence profile, we label it as the persona of a "TechnoSteward". The TechnoSteward profile combines the technical prowess and the responsible stewardship needed for AI in the public sector. The TechnoSteward possesses a deep understanding of technology, including the hands-on competence of software programming related to AI, but also the ability to translate concepts from a bureaucratic language to a language that is understandable by users of AI public services, and to apply data governance practices. At the same time, the TechnoSteward can access or exchange AI knowledge between different groups, establish collaboration between teams, and make decisions based on data.

This persona embodies a technologist mindset, which is however also able to consider, to some extent, the implications of public policymaking and theory, to engage in dissemination, and to collaborate with experts from other domains. This combination of competences is not only cross-disciplinary but also, and most importantly, likely to be realistic, because it comprises of competences that are not all equally difficult to obtain. Figure 3 illustrates the competence profile of the TechnoSteward using the AI4Gov Canvas.

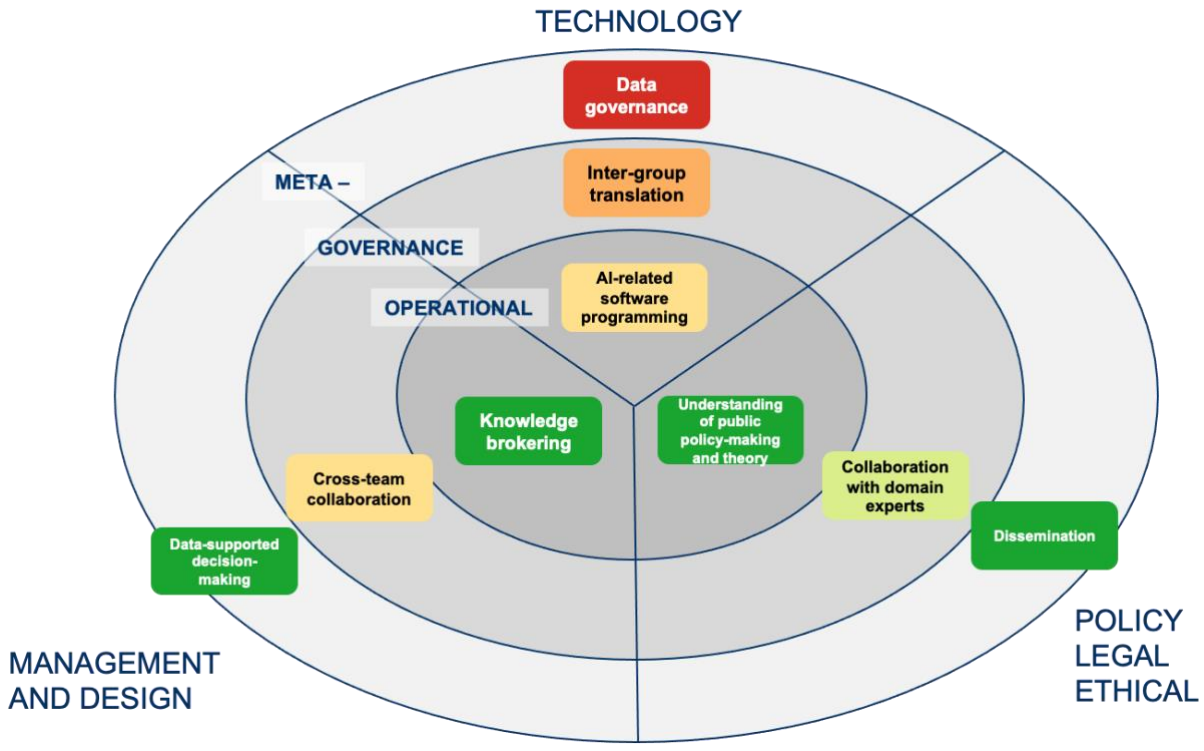

Fig. 3 - An illustration of the "TechnoSteward" competence profile.

5.2 Example 2: the Policy Sentinel

Using a similar approach, we showcase another exemplary profile that can be devised using the AI4Gov Functional Specialist Canvas.

This exemplary profile also combines nine competences in a persona that is realistically obtainable. We label this persona as the "Policy Sentinel", and illustrate its combination of competences in Table 2.

	Technology			**Management and design**			**Policy / legal / ethical**			**Total**	
		Imp.	*μ*		*Imp.*	*μ*		*Imp.*	*μ*	*Imp.*	*μ*
Operational	Data collection	136	89	Budgeting	84	90	**Specialized legal expertise**	98	121	*318*	*300*
Governance	Choice of machine learning techniques	100	95	Partnership development	103	100	**AI procurement literacy**	108	110	*311*	*305*
Meta-	Positive attitude towards AI	106	44	User-centricity	104	83	**Policy design**	113	111	*323*	*238*
		342	*228*		*291*	*273*		*319*	*342*	**952**	**843**

Tab. 2 - Competences of the "Policy Sentinel" functional specialist persona.

The competences for this example profile have also been selected within the constraint of a maximum of μ=900. However, the construction of this profile aims at having a special focus on the policy dimension. Therefore, all three competences in the policy / legal / ethical dimension have been chosen to have a very high coefficient of difficulty to obtain. These are (highlighted in bold type in Table 2): specialized legal expertise (μ=121), AI procurement literacy (μ=110), and policy design (μ=113).

On the other hand, in the other two dimensions (technology, management and design), competences with low coefficients of difficulty have necessarily been selected. The three least difficult competences (highlighted in red in Table 10) are, in fact, a positive attitude towards AI (μ=44), and data collection (μ=89), in the technology dimension, and user-centricity (μ=83), in the management and design dimension.

For the rest of the competences of this profile – whose sum of the coefficients of difficulty is as close as possible to 900, but without exceeding it (μ=843) – the Policy Sentinel encapsulates the persona's expertise in AI policy development, coupled with some relevant management and also some technological competences. "Sentinel" evokes a sense of watchfulness, indicating their role in safeguarding public interests and ensuring responsible AI governance. This persona is adept at navigating the regulatory landscape and shaping policies that strike a balance between innovation and policy and compliance considerations.

Figure 4 illustrates the competence profile of the Policy Sentinel using the AI4Gov Canvas.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

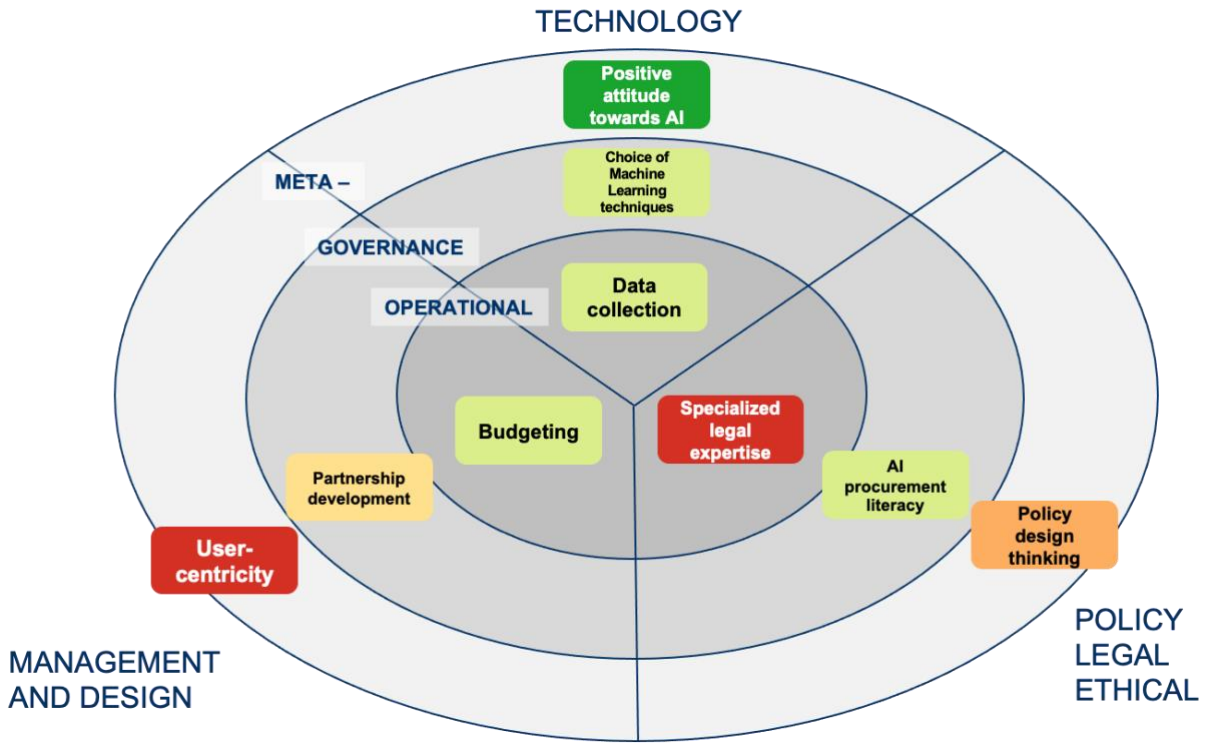

Fig. 4 - An illustration of the "Policy Sentinel" competence profile.

The Policy Sentinel features an in-depth understanding of the AI policy landscape, with specialized legal expertise, familiarity with the practices of procuring AI, and adopting a design thinking approach for devising and implementing AI policies in an iterative and user-centered way. But this persona is also able to budget, to develop partnerships, and to grasp technological dilemmas, such as choosing the right type of machine learning techniques needed in a specific situation.

Being generated within the constraints of the AI4Gov Canvas, this blend of competences spans various dimensions and is likely to be achievable, since it includes competences that vary in difficulty to acquire.

6. Lessons learned and next steps

Developing a competence framework for a Functional Specialist in AI for public services is crucial for ensuring that professionals in this domain have the necessary skills and expertise. However, it can be considered as a first step in the broader journey of investigating competence profiles for the future of AI in the public sector.

To continue developing the framework and to put it into fruitful use, we propose the following lines of action:

1) Refining / integrating the list of competences

This action involves further refining the list of competences required for AI specialists in the public sector. It may include reviewing industry standards, consulting experts, and considering specific job roles within the sector. Integration of competences should ensure that the framework covers all relevant skills and knowledge areas.

2) Soliciting feedback on clustering and levels of importance / difficulty to obtain

This action involves seeking further feedback from subject matter experts, practitioners, and stakeholders for validating the clustering of competences and determining their relative importance and difficulty to obtain. This feedback will help prioritize competences and create a more realistic framework. Moreover, it will help mitigating one of the limitations of the current version of the Canvas, which is the limited number of survey respondents on which its coefficients are based.

3) Soliciting feedback on the usability of the framework

Usability testing is vital to ensure that the competence framework is user-friendly. This action involves collecting feedback from potential users to identify any usability issues, such as unclear language, or confusing terminology,

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

and make necessary adjustments. This testing should involve different user personas, including entry-level AI specialists, mid-career professionals, and senior leaders. Mechanisms for users to provide feedback on the framework's usability should be included, to collect and analyse user feedback and allow iterative improvements.

4) Identifying use cases for the framework

This action is concerned with systematically identifying various use cases for the AI4Gov Canvas. Given that competence frameworks are non-binding, users are not obligated to follow them rigidly. Instead, they are encouraged to apply them with flexibility, allowing for customization and adaptation to suit their specific needs (Bacigalupo, 2022).

Uses of the Canvas that should be further explored include:

- *Training and development*. The most immediate use of the Canvas can be experimented with in the educational programme of the AI4Gov Master on Artificial Intelligence in the Public Sector. The Canvas can guide the design of training and development programs for AI specialists. Within public organizations, the Canvas can be used to ensure that employees receive the necessary training to engage with AI.
- *Self-assessment.* The tool can serve as a self-assessment platform, allowing public managers to evaluate their current competences, identify areas for improvement, and set personal development goals.
- *Career development.* public managers can use the framework to plan their career trajectories and identify the competences needed for advancement in their roles.
- *Recruitment and hiring.* Public sector organizations can utilize the framework as a reference when recruiting AI specialists. The Canvas can help in creating job descriptions, evaluating candidates, and aligning hiring practices with competence requirements.
- *Performance evaluation.* Managers and supervisors can use the framework to assess the skills and competences of their team members, facilitating more informed performance evaluations.
- *Benchmarking and reporting.* The tool can support the creation of reports and benchmarks to help public organizations track the overall competence level of their workforce and to identify areas where further investment is needed.

5) Integrating with existing frameworks

This action focuses on developing compatibility and integration with existing competence frameworks in the field of AI competences, such as those from national governments and international organizations. This integration can enhance the credibility and usefulness of the framework and reduce redundancy. For example, an immediate possibility for integration of the AI4Gov Canvas is with the UNESCO framework "*Artificial Intelligence and Digital Transformation: Competences for Civil Servants* (Broadband Commission, 2022), as also suggested in Misuraca *et al.* (2024). The alignment with the UNESCO framework would allow for the extension of the scope of the AI4Gov Canvas to a global horizon, beyond the one of Europe. The integration between the two frameworks could be based on the complementarity between the focus that the AI4Gov Canvas has on *individual* competences, and the focus of the UNESCO framework on *organizational* capabilities.

6) Guideline for an ecosystem of digital talent in AI, data spaces and digital transformation of the public sector

Finally, the authors have also used the AI4Gov Canvas as the foundation of the four-year AI4Gov-Accelerate project (2025-2029), funded by the Digital Europe Programme of the European Commission, that seeks to strengthen public administrations by enhancing their ability to attract digital talent and by fostering an educational ecosystem primed for innovation in AI, data spaces, and digital governance transformation. The AI4Gov Canvas has shaped the three key components – AI4Gov-X, AI4Scale, and AI4Engine – that collectively serve as core pillars of this project. First, the AI4Gov-X educational platform formalizes the knowledge base through a master program complemented by micro-credentials and extracurricular training, empowering participants with the skills required by rapidly evolving digital transformations where the AI4Gov Canvas will help participants to select their learning path. The AI4Scale sandbox then extends these learnings into practice by offering a collaborative environment where AI applications can be deployed, tested, and incubated, thus bridging academia, industry, and the public sector and again completing the practical skills addressed in the AI4Gov Canvas. Last, the AI4Engine innovation mapping – in the shape of an AI agent – is expected to serve as new input for the evolution of the AI4Gov Canvas by identifying emerging trends, and best practices on a global scale. By bringing these three elements together, AI4Gov Canvas not only cultivates individual competencies but also provides guidelines for human-centric AI-based public services.

7. Conclusion

As public organizations face the challenges of designing, implementing, and managing AI applications, the need for equipping public servants with the relevant competences becomes increasingly pressing. Given the specificity of artificial intelligence and its benefits and risks, the definition of competences needs to be not only as focussed and as granular as possible, but also grounded in empirical data. Our proposal, the AI4Gov Canvas, is an attempt to establish a data-driven competence framework that not only draws on an analysis of existing research and policy documents, but that also grounds it claims on empirical data from relevant actors involved in AI projects.

We hope that the framework can serve both as a tool for conceptualizing AI competences in the public sector; but also as a practical instrument that practitioners can use in strategic and tactical decisions related to the adoption of AI in the public sector.

Acknowledgments

The research underpinning this paper has been conducted as part of the AI4Gov Master on Artificial Intelligence for Public Services, a project co-funded by the European Union under the Connecting Europe Facility – CEF Telecom Programme (Grant Agreement number: INEA/CEF/ICT/A2020/2265375) and implemented by the Universidad Politécnica de Madrid (UPM) and Politecnico di Milano (POLIMI). Appendix A

Technology competences

Level of abstraction	*Competence label*	*Description*	*Coefficient of importance*	*Coefficient of difficulty to obtain (μ)*
Meta-competences	Foundational knowledge of AI	Being able to understand the fundamentals of AI at the conceptual level	129	116
	Data governance	Being able to apply data governance practices	124	169
	Positive attitude towards AI	Being able to have a positive attitude towards AI technologies in the public sector	106	44
	Basic data literacy	Being able to understand the basics of data	95	78
	Technical design	Being able to approach innovation of AI technology in an iterative and user-centered way	91	93
	Technology inquisitiveness	Being able and willing to keep learning on new developments in AI	86	109
	Data-oriented culture	Being able to think of data as central in the activity of a public manager	86	102
	Awareness of fairness challenges	Being able to be aware of challenges to fairness in the use of AI technologies	83	89
Governance competences	Technical fairness risk mitigation	Being able to assess fairness risks of AI and to mitigate these risks through technical instruments	126	105
	Inter-group translation	Being able to translate concepts from a bureaucratic language to a language that is understandable by users of AI public services	120	113
	Choice of machine learning techniques	Being able to know when to use a certain algorithm, tool, and library in specific situation	100	95

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Level of abstraction	*Competence label*	*Description*	*Coefficient of importance*	*Coefficient of difficulty to obtain (μ)*
	Choice of AI architecture	Being able to know when and how use which AI architecture and why (e.g., cloud infrastructure)	97	105
	Compliance with AI technical standards	Being able to adhere to and develop AI based on ethical and legal technical standards	95	97
	Re-use of AI-related components	Being able to reuse AI-related components from other sources during the development of AI solutions	91	107
	Data sharing	Being able to share data for AI-related purposes	70	78
Operational competences	Data collection	Being able to collect data for AI-related purposes	136	89
	Data quality assessment	Being able to assess the quality of data for AI-related purposes	133	90
	Understanding the fundamentals of machine learning	Being able to understand key objectives and applications of machine learning	133	91
	Understanding of causal analysis and decision theory	Being able to understand cause and effect relationships and being aware of decision theory related to data science practice	111	105
	AI-related software programming	Being able to use relevant programming languages for the development of AI, such as Python and R	87	114
	Database management	Being able to conduct data and database management effectively	83	107
	Understanding of computer vision and Natural Language Processing	Being able to understand AI computer vision and natural language processing	73	111
	Understanding of applied maths	Being able to understand and use applied mathematics	43	93

Management and design competences

Level of abstraction	*Competence label*	*Competence description*	*Coefficient of importance*	*Coefficient of difficulty to obtain (μ)*
Meta-competences	Problem identification and framing	Being able to identify and distinguish between different types of problems that require either data science or another approach	130	124
	Foresight	Being able to anticipate future needs of functional managers, suppliers and customers and proactively design AI solutions to support these needs	106	121
	User-centricity	Being able and willing to collaborate with users of AI digital services and valuing their feedback	104	83
	Leadership	Being able to lead to support AI initiatives	100	96
	Data-supported decision-making	Being able to make decisions based on data	96	76
	AI benefits understanding	Being able to understand the benefits of AI	90	83
	Risk proclivity	Being able to take risks in pursuing AI projects	89	107
	Digital-by-design thinking	Being able to think digital first in thinking of new AI services, policy, and practices	85	109
Governance competences	Change leadership	Being able to identify opportunities to improve the organisation and overcome structural and institutional obstacles to change	119	118
	Risk anticipation and mitigation	Being able to anticipate and mitigate risks of AI (e.g., privacy, security and ethical)	114	116
	Multidisciplinarity	Being able to blend traditional public service skills with modern digital skills	104	93

Abstract. This paper examines the emerging models of national competent authorities under the European Union's Artificial Intelligence Act (AI Act), providing novel insights into how different jurisdictions approach AI governance institutionalization. Through systematic analysis of official documents from early implementing Member States, we identify three fundamental dimensions that characterize distinct regulatory approaches. First, the organizational architecture reveals a spectrum from centralized to fragmented oversight models, reflecting different philosophies about coordinated versus distributed AI governance. Second, the institutional choices between leveraging existing regulatory bodies versus establishing new AI-specific authorities highlight contrasting approaches to building governance capacity and expertise. Third, the regulatory scope demonstrates a critical divide between horizontal and vertical oversight frameworks, with some jurisdictions pioneering hybrid solutions that attempt to balance specialized knowledge with coordinated supervision. Our methodology combines document analysis of legislative proposals, government resolutions, and administrative acts with a three-dimensional analytical framework examining degrees of centralization, institutional arrangements, and oversight models. The findings contribute to the theoretical understanding of AI governance by revealing how different jurisdictions interpret and operationalize regulatory requirements, balance competing institutional priorities, and address the complex challenge of overseeing AI systems. Furthermore, the analysis offers insights into the evolution of AI governance structures and contributes to the broader discourse on institutional design for emerging technology oversight. While our analysis is limited to early implementers and based primarily on formal documents rather than operational evidence, it provides a foundation for future research examining the effectiveness of different models, their evolution over time, and their impact on AI innovation and oversight. Future studies could benefit from comparative analyses of implementation outcomes, stakeholder perspectives, and the practical challenges of operationalizing these different governance frameworks.

Keywords. Artificial intelligence, European Union, AI Act, AI governance, National competent authorities
Research paper, DOI: https://doi.org/10.59490/dgo.2025.1007

1. Introduction

The rapid evolution of artificial intelligence (AI) technologies and their increased integration into various sectors have generated both enthusiasm and a greater level of attention towards policy frameworks and governance. The European Union (EU) has taken a pioneering step in this direction with the introduction of the Artificial Intelligence Act (Regulation (EU) 2024/1689), establishing the first comprehensive regulatory framework across European Member States. This regulation is designed to enhance innovation by fostering trustworthy AI, ensuring the protection of societal well-being (Laux, 2024), in compliance with EU values and fundamental rights. This highlights the need for robust oversight mechanisms to build public trust in AI technologies while guaranteeing a

flexible and comprehensive regulatory framework to accommodate cultural differences and bridge gaps across different national legal systems (Gasser, 2017). The AI Act, which came into force in August 2024, sets the standard framework that European Member States must comply with to ensure that society understands AI's capabilities and limitations, while promoting development and innovation (Lu, 2024). The AI Act also mandates the inclusion of diverse stakeholders in the governance scheme to ensure equitable representation and avoid potential biases (Cancela-Outeda, 2024). Since the conclusion of the technical negotiations in January 2024, Member States have adopted various strategies to implement the new regulation. The challenges they face are primarily focused on resource allocation, both financial and human. The latter is particularly driven by the complexity of the matter, which demands expertise from diverse fields as the technology evolves (Cancela-Outeda, 2024) with regulatory standards, addressing ethical concerns, and promoting transparency in AI decision-making (Bellogìn, 2024). This paper provides a comparative analysis of the implementing approaches adopted by European Member States in response to the European Union's Artificial Intelligence Act, in terms of national governance of artificial intelligence systems. It focuses on the legal and governance repercussions and emphasizes the diversity of models implemented at the national level, ranging from centralized to fragmented systems. While other scholars identified the possible divergences in the selection of national competent authorities by Member States (Novelli, 2024), comprehensive studies in the field are still limited. The aim is to offer practical insights into the challenges and opportunities of AI governance implementation. The paper is organized as follows: this first section introduces the key features of AI governance and its objectives. The second section presents research methods. The third section highlights the legal framework (AI Act), together with the implementation challenges related to the complexity of the regulatory infrastructure that should guarantee both effective surveillance and operational capabilities. The fourth is a detailed analysis of the different national models adopted, ranging from centralized to fragmented, from existing bodies to newly established institutions, and from horizontal to vertical oversight, mainly because of different national administrative and economic needs. The fifth presents the main discussion of the governance paths encountered. The final section offers conclusions and recommendations for policymakers, together with the limitations and potential future directions of the research.

2. Research methods

2.1 Document analysis

The document analysis process relied on official legislative and administrative sources from EU Member States. Our data collection focused on four main categories of official documents: (1) legislative proposals submitted to national parliaments; (2) government resolutions and administrative acts; (3) official online communications from relevant ministries and regulatory bodies; and (4) draft laws and amendments to existing legislation. These documents were collected through systematic monitoring of official government websites, parliamentary databases, and official journals of Member States. To ensure comprehensiveness, we based our research on documents in their original languages, employing translations, when necessary, which inevitably introduces interpretive considerations and risk of misinterpretation. The selection criteria required documents to: (a) explicitly address the implementation of Articles 28 and 70 of the AI Act regarding competent authorities, (b) represent formal government positions rather than preliminary or unofficial proposals, and (c) contain specific details about institutional arrangements and governance structures. This approach allowed us to focus on concrete implementation steps while excluding general policy discussions or preliminary proposals that had not reached formal legislative or administrative status. In some cases, such as Cyprus and Malta, we supplemented documentary evidence with correspondence with officials of the relevant institutions. While this enhanced our understanding of these specific cases, the dynamic nature of implementation processes across Member States suggests that current institutional arrangements may continue to evolve beyond what is captured in official documentation. This initial mapping provides a foundation for ongoing research as the practical implementation of the AI Act unfolds across the European Union.

2.2 Temporal framework

In addition, this research adopts a defined temporal framework shaped by two key dates: the entry into force of the EU AI Act (August 2024) and our data collection cutoff date (April 2025). This timeframe captures the initial months of implementation efforts by Member States, providing insights into early strategic approaches while acknowledging that the process remains ongoing until the deadline of August 2025 set by the AI Act for appointing national competent authorities. The decision to analyze this early implementation period, rather than waiting for the complete implementation across all Member States, is methodologically significant for several reasons. First, it allows us to identify emerging patterns and potential challenges in the implementation process as they unfold, providing valuable insights for Member States still developing their approaches. Second, examining early adopters' choices helps understand different interpretative approaches to the AI Act's requirements, particularly regarding institutional arrangements and governance models. Finally, while this temporal limitation means our analysis cannot capture the complete EU-wide implementation landscape, it offers a crucial snapshot of how Member States

with different administrative traditions and regulatory capacities interpret and operationalize the AI Act's requirements for competent authorities.

2.3 Comparative analysis

Considering the insights already identified in the different patterns of AI national competent authorities (Novelli, 2024), the analysis employs a three-dimensional framework developed to systematically examine different implementation models. This framework emerged from iterative analysis of the implementation approaches and theoretical considerations from the literature on regulatory governance. The first dimension analyzes the degree of centralization in oversight responsibilities, categorizing approaches as centralized (single government authority with broad mandate), unified (single independent authority), or fragmented (multiple authorities with distributed responsibilities). The second dimension examines institutional choices between leveraging existing regulatory bodies versus establishing new AI-specific institutions, focusing on how Member States balance their organizational needs with the deadlines of the AI Act. The third dimension considers the scope of oversight, distinguishing between sectoral/verical approaches (domain-specific regulation) and broad/horizontal oversight (comprehensive cross-domain supervision). For each dimension, we developed specific indicators to ensure consistent categorization: centralization is assessed through the number and hierarchical relationships of designated authorities; institutional choice is evaluated based on whether new bodies are created, or existing ones are empowered; and oversight scope is determined by examining the breadth of regulatory mandates and coordination mechanisms. While limited in scope, this framework enables systematic comparison while accommodating the complexity and diversity of national implementation strategies.

2.4 Clustering

The clustering methodology involved a systematic comparison of national implementation models based on their shared characteristics and divergences. We first developed a comparative matrix (presented in Table 1) mapping each country's designated authorities against two key variables: type of national authority (market surveillance and notifying) and governance approach (government control vs. independent body). This initial mapping enabled the identification of distinct implementation clusters. The clustering process followed three sequential steps: first, countries were grouped based on their primary organizational approach (centralized, unified, or fragmented); second, within each primary cluster, we analyzed sub-patterns related to institutional choices (existing vs. new bodies) and oversight models (sectoral vs. horizontal); finally, we examined outlier cases and hybrid approaches that combined elements from different models. This multi-level clustering approach revealed not only the predominant implementation patterns but also the nuanced variations within each cluster, particularly in how Member States balance different institutional and governance requirements.

3. Theoretical background

The theoretical background of this research is the European Union's Artificial Intelligence Act, or AI Act (Regulation (EU) 2024/1689). The AI Act establishes a comprehensive framework for the regulation of artificial intelligence systems in the European Union, requiring Member States to designate or establish competent authorities for its implementation. These authorities, comprising market surveillance authorities (art. 70) and notifying authorities (art. 28), are fundamental to ensuring compliance with the regulation's requirements and maintaining oversight of AI systems within the EU market.

3.1 Legal framework

The AI Act defines two types of competent authorities: market surveillance authorities and notifying authorities. While Member States have the flexibility to designate or establish these authorities according to their organizational needs, the regulation sets forth strict requirements regarding their independence, resources, and operational capabilities. A key principle established by Article 70 is that these authorities must "exercise their powers independently, impartially and without bias so as to safeguard the objectivity of their activities and tasks." This independence in exercising their powers is crucial for ensuring effective oversight of AI systems and maintaining public trust in the regulatory framework.

3.2 Market surveillance authorities

The market surveillance authority plays a crucial role in the AI Act's enforcement mechanism. While building upon established market surveillance principles from Regulation (EU) 2019/1020, the AI Act extends these authorities' responsibilities to address the unique challenges of AI systems under Article 70 provisions. Market surveillance authorities - responsible for the national supervision of AI systems - may take measures in relation to all AI systems when they present a risk in accordance with the AI Act (e.g. high-risk AI systems in the area of biometrics), perform market surveillance duties under Article 74 and report to the European Commission about the use of prohibited practices that occurred during that year and about the measures taken. Member States must designate one market surveillance authority as their single point of contact for the AI Act, creating a clear channel for coordination at

both national and EU levels. This designation facilitates the exchange of information and best practices among authorities across Member States, as encouraged by Article 70(7).

3.3 Notifying authorities

Article 28 outlines distinct responsibilities for notifying authorities, focusing on their role in the conformity assessment ecosystem. Their core functions include: (1) setting up and carrying out procedures for assessment of conformity assessment bodies, (2) designating and notifying these bodies, (3) monitoring their ongoing compliance, and (4) developing these procedures in cooperation with other Member States' notifying authorities. To maintain integrity in the assessment process, notifying authorities must: ensure decisions about notification are made by different personnel than those conducting assessments, avoid any conflicts of interest with conformity assessment bodies, refrain from offering services that conformity assessment bodies perform, maintain strict confidentiality of information obtained during their activities.

3.4 Structural and organizational requirements

The regulation provides Member States with significant flexibility in organizing their competent authorities. Article 70(1) explicitly states that the activities and tasks may be performed by one or more designated authorities, according to each Member State's organizational needs. However, this flexibility is balanced with specific structural requirements: (1) at least one notifying authority and one market surveillance authority must be designated, (2) one authority must be designated as a single point of contact, (3) information about how to contact these authorities must be publicly available through electronic means, and (4) regular reporting to the Commission on resources and adequacy is required.

3.5 Resource and expertise requirements

The AI Act places significant emphasis on ensuring competent authorities are adequately resourced and staffed. Article 70(3) mandates that Member States must provide their national competent authorities with adequate technical, financial, and human resources, along with the necessary infrastructure to effectively fulfill their tasks under the regulation. Specifically, competent authorities must maintain a sufficient number of permanently available personnel with expertise in: AI technologies, data and data computing, personal data protection, cybersecurity, fundamental rights, health and safety risks, existing standards and legal requirements. Member States are required to assess and update these competences and resource requirements annually, ensuring their authorities maintain the capacity to address evolving technological challenges. This comprehensive expertise requirement reflects the complex and multidisciplinary nature of AI oversight (Dwivedi, 2021).

3.6 Implementation challenges

The implementation of competent authorities under the AI Act presents several significant challenges that Member States must address to ensure effective oversight of AI systems. The resource allocation requirement represents a substantial hurdle, as Member States must ensure adequate funding and staffing by 2 August 2025 to ensure the appointment of national competent authorities (Article 70(2)). From an institutional theory perspective, it might pose challenges in terms of competition among institutions for resource allocation (Shao, 2020). The biennial reporting obligation to the Commission on financial and human resources creates an ongoing accountability mechanism, but also highlights the sustained commitment required. Member States must not only secure initial funding but also maintain and potentially increase resources as the AI landscape evolves and regulatory demands grow, a global tendency in AI governance worldwide (Zaidan, 2024). In terms of AI governance frameworks, those authorities can represent the operationalization of the technical and the social/legal layers of the layered model for AI governance in Gasser and Almeida (2017). The need for personnel with deep understanding across multiple domains creates significant recruitment and retention difficulties. Competent authorities must compete with private sector employers who can often offer more attractive compensation packages to professionals with expertise in AI, data science, and cybersecurity. Moreover, the requirement for expertise in market surveillance and legal frameworks alongside technical knowledge creates a need for either rare multidisciplinary professionals or carefully balanced teams that can work effectively together. Indeed, the expertise requirements pose a particularly complex challenge in the current technology labor market (Medaglia, 2024). Coordination complexity emerges as another significant challenge, particularly in cases where AI systems intersect with multiple regulatory domains (Feijóo, 2020). The requirement for consultation with authorities under other EU legislation demands careful orchestration of administrative processes and decision-making procedures. This becomes especially challenging when time-sensitive decisions are required, or when different authorities may have overlapping or potentially conflicting perspectives on specific AI applications. The mandate to maintain operational independence while ensuring effective oversight creates institutional design challenges that go beyond simple organizational structures (Fountain, 2004). Member States must establish governance mechanisms that protect authorities from undue influence while maintaining appropriate accountability. This becomes particularly complex in Member States where regulatory responsibilities are distributed across multiple bodies, requiring careful balancing of autonomy and coordination.

4. Analysis of implementation models of competent authorities

This section analyzes the implementation pattern of countries that took concrete steps from a normative point of view (e.g. legislative proposals, regulations, mandates, etc.) to address the appointment of AI competent authorities under the EU AI Act (art. 28 and 70). The deadline set forth by the AI Act for the appointment of such authorities is 2 August 2025. In April 2025, most of the EU countries did not take official legislative steps to appoint neither the notifying authority, nor the market surveillance authority. These are Austria, Belgium, Bulgaria, Croatia, Czech Republic, Denmark, Estonia, France, Germany, Greece, Ireland, Latvia, Netherlands, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden. It should be noted that the AI Act is a text with European Economic Area relevance, meaning that it also applies to Iceland, Norway and Liechtenstein. Nonetheless, none of them appointed the national competent authorities before April 2025. It should also be noted that two countries, Cyprus and Malta, already identify competent authorities in their government websites, but with no implementing law in place at the moment of the analysis. These are marked as *planned*.

4.1 Cyprus (planned)

Cyprus has taken initial steps toward implementing the AI Act, with the Council of Ministers approving a national governance structure in January 2025 (Vice Minister of Research press release of 22 January 2025) to designate competent authorities for oversight. Cyprus has divided responsibilities between just two existing regulatory bodies, creating a streamlined system. The Commissioner for Communications serves multiple key roles: notifying authority, market surveillance authority, and the single point of contact required by the AI Act. This concentration of responsibilities reflects a centralized approach using existing regulatory infrastructure rather than creating new institutions. The Commissioner for Personal Data Protection serves as an additional market surveillance authority, specifically for matters related to its existing areas of application. This allocation of oversight responsibilities to the data protection authority follows a pattern seen in other Member States, recognizing the overlap between AI governance and data protection concerns. The Commissioner for Communications, which already has a broad mandate in electronic communications and postal services markets, extends its regulatory functions to encompass AI systems. This leverages existing regulatory expertise and infrastructure while expanding to address challenges presented by artificial intelligence. Without implementing legislation currently in place, specific procedural details and enforcement mechanisms remain undefined, including how the two designated authorities will coordinate their activities and how sanctions will be determined and applied for non-compliance with the AI Act's provisions.

4.2 Finland

In June 2024, the Finnish Ministry of Employment and the Economy issued a proposal to designate the independent AI authorities that would act as market surveillance authority and notifying authority (Government's bill n. TEM050:00 of 2024). The Finnish proposal distributes oversight responsibilities of market surveillance across multiple existing government regulatory bodies rather than creating a single centralized authority. The agencies that currently monitor product safety, transportation, digital systems, healthcare equipment, and financial markets – in addition to the data protection authority - extend their supervisory duties to include AI systems within their respective domains. Specifically, these are: the Safety and Chemicals Agency, the Transport and Communications Agency (also acting as the single point of contact referred to in Article 70(2) of the AI Act), the Ministry of Social Affairs and Health, the occupational safety and health divisions of Regional State Administrative Agencies, the Centre for Safety and Development of Medicinal Products, the Energy Authority, the South Savo Centre for Economic Development, Transport and the Environment, the Financial Supervisory Authority, the National Supervisory Authority for Welfare and Health, councilors elected by Parliament, and the Data Protection Supervisor. At the same time, the Ministry of Economic Affairs and Employment, the Transport and Communications Agency, the Medicines Agency, the Ministry of Social Affairs and Health, and the Data Protection Supervisor have been proposed as notifying authorities. Governance models emphasizing distributed authority potentially enhance substantive effectiveness through domain-specific expertise while introducing coordination challenges that compromise procedural efficiency. Recognizing this trade-off carries important implications for institutional design generally, highlighting the necessity of governance arrangements that maintain appropriate equilibrium between specialized expertise and coordination capacity.

4.3 Hungary

According to the latest resolution (Government resolution n. 1301of 2024), Hungary established the new Hungarian Artificial Intelligence Council, which shall perform the official tasks both of notifying and market surveillance authorities under the AI Act. The Council is established under the supervision of the Minister of National Economy. This single organization is designed to provide a streamlined "one-stop shop" for AI governance while fulfilling all the regulatory requirements prescribed by the AI Act, including serving as the mandated single point of contact. The institutional innovation strategy of establishing a new AI-specific body represents a distinctly different conceptualization of effective AI governance, one that prioritizes specialized focus and organizational adaptability over institutional continuity and established expertise.

4.4 Italy

The Italian Parliament (Senate Bill n. 1146 of 2024) proposed to appoint the National Cybersecurity Agency (ACN) as market surveillance authority with monitoring, inspection and enforcement powers, and the Agency for Digital Italy (AgID) as notifying authority. Both agencies - the first managing the national cybersecurity issues, the latter being the technical IT agency of the government - work under the supervision of the Presidency of the Council of Italy. The designation of a cybersecurity agency as the primary market surveillance authority reflects Italy's strategic view of AI governance as fundamentally intertwined with digital security concerns. AgID instead provides experience in developing technical standards, managing digital transformation initiatives, and coordinating public administration technology adoption. To ensure effective coordination, the legislation establishes a Coordination Committee at the Presidency of the Council of Ministers, composed of the directors general of both agencies and the head of the Department for Digital Transformation. This mechanism aims to maintain consistency in Italy's overall approach to AI governance despite the functional division between market surveillance and notification responsibilities.

4.5 Lithuania

In Lithuania, the amendments adopted by the government (Government resolution n. 860 of 2024) set out a specific role for the Innovation Agency, which, together with the Communications Regulatory Authority (*Lietuvos Respublikos ryšių reguliavimo tarnyba*, RRT), will be the main body responsible for implementing the EU's Artificial Intelligence Act. RRT is meant to be an agency transcending traditional supervisory functions to become a facilitative partner promoting coordination and multi-stakeholder dialogue. The Innovation Agency has been designated as the national notifying authority, while the Communications Regulatory Authority will act as the market supervisor and single point of contact. Innovation Agency Lithuania is a non-profit agency under the Lithuanian Ministry of Economy and Innovation. The Communications Regulatory Authority of the Republic of Lithuania is an independent state institution regulating electronic communications, postal, rail markets and as well as performing supervision of trust service providers. Lithuania's implementation approach for the AI Act reflects a pragmatic balance between centralization and specialization. By assigning distinct but complementary roles to two established agencies, Lithuania has created a governance structure that avoids both excessive fragmentation and complete consolidation

4.6 Luxembourg

Luxembourg's Parliament introduced a new law to enact the AI Act (Parliament bill n. 8476 of 2024). The bill outlines the designation of national authorities responsible for applying and monitoring the AI Act, including the Luxembourg Institute for Standardization, Accreditation, Safety and Quality of Products and Services and the Government Data Protection Commission as notifying authorities. It also designates the National Commission for Data Protection as the market surveillance authority for high-risk AI systems used by law enforcement and other sectors and specifies other authorities for market surveillance based on sectoral supervision. Namely: Judicial Supervisory Authority, Financial Sector Supervisory Commission, Supervisory Authority for the Insurance Sector, Luxembourg Institute for standardization, accreditation, safety and quality of products and services, Luxembourg Regulatory Institute, Luxembourg Agency for Medicines and Health Products, and the Luxembourg's independent audiovisual authority. On top of this, as the horizontal market surveillance authority by default, the Commission for Data Protection (*Commissariat du gouvernement à la protection des données auprès de l'Etat, CGPD*) is responsible for coordination with market surveillance authorities and designated as the single point of contact. Luxembourg's approach to implementing the AI Act reveals a distinctive regulatory philosophy that emphasizes highly specialized oversight distributed according to existing regulatory competencies. This fragmented governance structure may offer advantages in terms of leveraging deep domain expertise but also creates potential coordination challenges that the CNPD, in its role as coordinator, will need to address.

4.7 Malta (planned)

As mentioned in their official websites in January 2025 and confirmed by their officials in January 2025 via direct correspondence, the Malta Digital Innovation Authority (MDIA) and the Information Data Protection Commission (IDPC) have been identified as market surveillance authorities in Malta by the latest draft government law. At the same time, the MDIA and the National Accreditation Board have been identified as notifying authorities. The MDIA is the primary government authority responsible for promoting governmental policies that promote Malta as the center for excellence for technological innovation. The IDPC is the national independent supervisory authority responsible for upholding the fundamental right of individuals to have their personal data protected and to monitor the application of data protection law in Malta. This designation reflects the Act's emphasis on protecting fundamental rights and freedoms of individuals potentially affected by autonomous decision-making technologies, with particular focus on transparency, security, data protection, robustness, accuracy, non-discrimination, and sustainability principles. The National Accreditation Board is a public entity, with no share ownership, commercial or other interest in any conformity assessment body and it operates on a not-for-profit basis. It is responsible for accreditation in accordance with the relevant national, international and European standards and guides, and the

applicable national, international and European regulations. This regulatory architecture demonstrates Malta's strategic approach to implementing the AI Act while leveraging existing institutional competencies.

4.8 Poland

The Polish draft act on artificial intelligence systems (Government bill n. UC71 of 2024) planned to establish a new market surveillance authority for artificial intelligence models and systems, which will be the Artificial Intelligence Development and Security Commission. The work of the Commission will be managed by the Chairman appointed by the Prime Minister of Poland. It is also proposed to designate the Department of Digital Affairs of the Chancellery of the Prime Minister of Poland, the institution responsible for computerization, as the authority responsible for notification of conformity assessment bodies and as the notifying authority. Poland has opted for a primarily consolidated regulatory architecture with clearly defined jurisdictional boundaries. This approach reflects Poland's strategic decision to create dedicated AI governance institutions rather than distributing responsibilities across existing regulatory bodies, enabling more focused expertise development while maintaining centralized coordination.

4.9 EU Institutions

Finally, as regards AI systems put into service or used by European Union institutions, the AI Act references to national competent authorities or market surveillance authorities shall be construed as references to the European Data Protection Supervisor (EDPS). In fact, artt. 70 and 74 state that where Union institutions, bodies, offices or agencies fall within the scope of the AI Act, the European Data Protection Supervisor shall act as the competent authority for their supervision, and as their market surveillance authority, except in relation to the Court of Justice of the European Union acting in its judicial capacity. The EDPS is an independent supervisory authority responsible for ensuring that EU institutions and bodies comply with data protection law when processing personal data.

Tab. 1 summarizes the results of the research.

Tab. 1: Emerging governance models of national competent authorities under the EU AI Act (*last update: January 2025*)

Country	Type of national authority	Institution	Governance	
			Government control	Independent body
Cyprus	Market surveillance authorities	Commissioner for Communications	X	
		Commissioner for Personal Data Protection		X
	Notifying authority	Commissioner for Communications	X

5. Discussion

5.1 Centralized, unified, fragmented approaches

The analysis of early implementations of AI Act national competent authorities reveals three distinct organizational approaches among Member States. While most EU countries have yet to designate their competent authorities, the emerging patterns from early adopters provides valuable insights into different implementation strategies. These divergent implementation strategies reflect fundamental differences in administrative traditions, institutional capacities, and conceptualizations of effective technology governance across the European regulatory landscape. The centralized approach, adopted by Hungary, Italy, and Poland, places both market surveillance and notifying authority functions under direct government control. This approach suggests a preference for strong governmental coordination in AI oversight, potentially facilitating faster decision-making and unified policy implementation. The Hungarian model exemplifies this approach through its establishment of the Artificial Intelligence Council under the direct supervision of the Minister of National Economy, creating a consolidated institutional structure with comprehensive authority over AI oversight functions. Similarly, Poland's proposed Artificial Intelligence Development and Security Commission and Italy's designation of government agencies under the Presidency of the Council demonstrate variations of this centralized institutional design. However, this model also raises questions about the independence of oversight mechanisms, particularly given the AI Act's emphasis

on authorities exercising their powers "independently, impartially and without bias" (Article 70). The unified approach, interestingly, has only been adopted by EU institutions through the European Data Protection Supervisor (EDPS). This model combines both functions within a single independent authority, potentially offering clearer lines of accountability and more streamlined operations. However, its limited adoption by Member States might suggest practical challenges in implementing this approach at the national level, where existing regulatory landscapes are more complex, the market presents more AI systems for market surveillance activities, and robust capacity in AI is needed, notably towards the need for public acceptance (Middleton, 2022). The predominant avoidance of this model by early implementing Member States indicates significant practical barriers, potentially including resource constraints, institutional path dependencies, and challenge in developing the multidimensional expertise necessary for comprehensive AI oversight within a single independent regulatory entity. The fragmented approach emerges as the predominant choice among early implementers, with countries like Finland, Lithuania, Luxembourg, and Malta adopting various mixed models. Within this landscape, institutional arrangements vary from moderately distributed (e.g., Lithuania's dual-agency model) to highly complex configurations (e.g., Luxembourg's eight-authority framework). The distributed approach operationalizes theoretical insights regarding the diversity of expertise necessary for effective technology governance, acknowledging that different regulatory domains require distinct forms of specialized knowledge that may not be readily consolidated within singular institutional structures. This organizational fragmentation potentially enhances the depth of domain-specific understanding but simultaneously creates significant coordination burdens and risks of inconsistent implementation across regulatory domains. Luxembourg's implementation particularly exemplifies this approach, with multiple sectoral authorities sharing market surveillance responsibilities while maintaining the National Commission for Data Protection as a horizontal coordinator. Similarly, Lithuania combines a government agency for notification with an independent authority for market surveillance. This approach potentially leverages existing expertise across different domains – that requires developing a nuanced understanding of a highly complex policy landscape (Margetts, 2024) – but may face increased administrative complexity and coordination challenges (Mikhaylov, 2018). The prevalence of the fragmented approach among early implementers might indicate a pragmatic response to the AI Act's comprehensive requirements. By distributing responsibilities across existing bodies, Member States can potentially meet the August 2025 deadline while leveraging established regulatory expertise. However, this choice also reflects the complexity of AI governance, where different aspects of oversight may require distinct types of regulatory approaches and expertise (Choi, 2023). These early implementation patterns also reveal an important tension between the need for coordinated AI oversight and the practical advantages of distributed regulatory responsibility. While centralized approaches might offer more straightforward coordination, fragmented implementations might better address the multifaceted nature of AI regulation, from technical standards to market surveillance duties.

5.2 Institutional continuity vs. new bodies

The results also reveal a clear dichotomy in institutional approaches to AI oversight, with most Member States opting to leverage existing regulatory bodies while only a few create new AI-specific institutions. This pattern offers important insights into different strategies for building AI governance capacity. The majority of early implementing states have chosen to adapt and expand the mandates of existing institutions. Finland distributed oversight responsibilities across established regulatory bodies in various sectors, while Luxembourg designated existing authorities like the Institute for Standardization, Accreditation, Safety and Quality of Products and Services and National Data Protection Commission for different aspects of AI oversight. Similarly, Italy appointed its National Cybersecurity Agency and Agency for Digital Italy, while Malta leveraged the existence of its Digital Innovation Authority and the Data Protection Commission. This approach suggests a pragmatic strategy that capitalizes on established regulatory expertise and existing strong institutional frameworks (Winfield, 2018). It may also reflect practical considerations regarding the ambitious implementation timeline, as creating entirely new institutions by August 2025 could present significant organizational challenges. In contrast, Hungary and Poland have opted to establish new AI-specific bodies. Hungary's creation of a dedicated AI Council and Poland's proposed Artificial Intelligence Development and Security Commission represent a more transformative approach to AI governance. These new institutions might offer advantages in terms of specialized focus and clear mandate, but they also face the challenge of building regulatory capacity and expertise from the ground up. The choice to create new bodies might reflect these countries' vision of AI oversight as a distinct regulatory domain requiring dedicated institutional frameworks rather than an extension of existing regulatory functions, highlighting the tension in diverse AI public management and organization (Selten, 2024). This approach acknowledges that effective AI oversight requires diverse forms of what may already exist within established regulatory frameworks. Moreover, building on existing institutions might facilitate faster operational capability and more efficient resource utilization, particularly important given the comprehensive expertise requirements outlined in Article 70(3) of the AI Act. However, the institutional continuity approach also presents potential challenges. Existing bodies may need significant adaptation to handle AI-specific oversight responsibilities, and there might be risks of institutional path dependency (Chiodo, 2024), limiting the development of novel regulatory approaches needed for AI governance. Conversely, while new AI-specific bodies might offer more flexibility in developing tailored oversight mechanisms, they face the substantial challenge of building institutional capacity and expertise within a limited timeframe. This institutional design dichotomy reflects deeper theoretical questions regarding the nature of effective technology governance - specifically, whether novel technological systems like artificial intelligence represent extensions of

existing regulatory domains requiring evolutionary adaptation or fundamentally different governance challenges necessitating revolutionary institutional transformation. The empirical evidence from early implementation patterns suggests that most jurisdictions have adopted the former perspective, conceptualizing AI governance as an extension of existing regulatory domains that can be effectively addressed through institutional adaptation rather than creation.

5.3 Vertical vs. horizontal oversight

Finally, the examination of Member States' implementation choices highlights a critical divide between comprehensive and domain-specific regulatory architectures for AI oversight, each reflecting distinct philosophies about effective AI governance. At one end of the spectrum lies the vertical and domain-specific model, with Finland and Luxembourg as prime examples of jurisdictions embracing specialized regulatory frameworks. The Finnish implementation distributes competencies across multiple domain experts, from transport regulators to healthcare authorities, while Luxembourg's framework carefully delineates oversight based on sector-specific expertise. This granular approach stems from an understanding that AI systems pose distinct challenges depending on the application context (Alhosani, 2024), demanding tailored oversight mechanisms. Standing in stark contrast is the comprehensive oversight model, epitomized by Hungary and Poland's approaches through their dedicated AI authorities. By establishing single entities with broad supervisory mandates, these Member States prioritize unified governance over sector-specific considerations. Their implementation strategy suggests a conception of AI oversight as fundamentally cross-cutting, requiring coordinated supervision that transcends traditional regulatory boundaries (Taeihagh, 2021). This fundamental divergence in regulatory architecture carries significant implications. The domain-specific model offers the advantage of nuanced, context-aware supervision but risks creating regulatory silos and inconsistent interpretation of AI Act requirements. Meanwhile, comprehensive oversight promises more uniform implementation but may struggle to address the technical intricacies and operational specificities of different sectors. Some jurisdictions are developing hybridized frameworks that attempt synthetic reconciliation of these competing architectural principles (e.g. Cyprus, Malta). Though empirical validation of this approach's effectiveness remains pending, its theoretical framework suggests potential for balancing competing regulatory imperatives. This balanced framework might offer valuable insights for other Member States still formulating their implementation strategies, though its practical effectiveness remains to be evaluated. The emergence of these architectural variations demonstrates the complex multidimensionality of AI governance, requiring institutional frameworks capable of simultaneously addressing cross-cutting principles and sector-specific requirements The diversity of architectonic approaches among early-implementing Member States illuminates the fundamental governance challenge of balancing systemic coherence with contextual adaptability, revealing tensions between implementation uniformity and calibration that persist across diverse administrative contexts.

6. Conclusion

Our analysis of early implementation approaches to the EU AI Act's requirements for national competent authorities reveals fundamental dimensions that characterize distinct regulatory strategies. First, regarding organizational architecture, while most EU countries have yet to designate their competent authorities, early implementers show a clear pattern. The fragmented approach emerges as predominant, with countries like Finland, Lithuania, Luxembourg, and Malta distributing responsibilities across multiple bodies. In contrast, Hungary, Italy, and Poland opted for more centralized models, while the unified approach has been primarily adopted only at the EU institutional level through the EDPS. The predominance of fragmented approaches among early implementers suggests a pragmatic recognition of AI's complex, multi-faceted nature and the diverse expertise required for effective oversight. While this distributed model leverages specialized knowledge across different domains, it also introduces significant coordination challenges that Member States must address through careful institutional design. Second, our analysis reveals a strong preference for leveraging existing regulatory bodies over establishing new AI-specific institutions. Most early implementing states, including Finland, Luxembourg, Malta, and Italy, chose to expand the mandates of established authorities, likely capitalizing on existing expertise and institutional frameworks. Only Hungary and Poland opted to create new dedicated AI oversight bodies, highlighting different philosophies about building regulatory capacity. The strong preference for leveraging existing regulatory bodies over creating new AI-specific institutions reflects both practical and strategic considerations. This approach allows Member States to build on established expertise and operational capabilities, potentially facilitating faster implementation given the AI Act's ambitious timeline. However, this choice also raises questions about whether traditional regulatory frameworks can adequately adapt to the unique challenges of AI oversight. Third, we observed a critical divide between comprehensive and domain-specific oversight frameworks. While some jurisdictions like Finland and Luxembourg embraced specialized regulatory frameworks across different sectors, others like Hungary and Poland prioritized unified governance through broad supervisory mandates. Notably, some states are pioneering hybrid solutions that attempt to balance specialized knowledge with coordinated supervision. The tension between sectoral and horizontal oversight models emerges as a critical challenge in institutional design. While sector-specific approaches offer deeper domain expertise and contextual understanding, they risk creating regulatory fragmentation and inconsistent interpretation of AI Act requirements. Conversely, comprehensive oversight models promise more uniform implementation but may struggle to address

sector-specific technical complexities. Early implementing states' diverse approaches to resolving this tension provide valuable insights for other Member States still formulating their implementation strategies. Looking forward, these early implementation choices may have lasting implications for the effectiveness of AI oversight in Europe. The institutional architecture being established now will likely shape how Member States approach future challenges in AI governance, from ensuring consistent interpretation of requirements to fostering innovation while maintaining adequate oversight. Moreover, these diverse approaches to implementing the AI Act may offer valuable lessons for other jurisdictions worldwide as they develop their own AI governance frameworks.

Several important limitations of this study should be acknowledged. Our analysis focuses on early implementing Member States during the initial months following the AI Act's entry into force, capturing only the first wave of implementation approaches. This temporal limitation, while providing valuable early insights, means our findings may not fully reflect the complete landscape of implementation strategies that will emerge as more Member States designate their competent authorities. Additionally, our analysis relies primarily on formal documents and legislative proposals rather than operational evidence, as these authorities are not yet fully functioning. These limitations point to important directions for future research. First, longitudinal studies tracking the evolution of these different regulatory models would provide valuable insights into their effectiveness and adaptability over time. As Member States operationalize their institutional frameworks and develop practical coordination mechanisms, comparative assessment of regulatory outcomes would illuminate how different structural arrangements influence governance effectiveness. Second, comparative governance studies across technological domains would enhance understanding of whether findings from AI governance extend to other emerging technologies. Research examining institutional arrangements for quantum computing, biotechnology, or autonomous systems governance could identify common patterns and distinctive challenges, potentially revealing domain-specific factors that influence optimal institutional design. Third, research examining stakeholder perspectives, including industry actors and civil society, would enhance understanding of how different institutional arrangements impact innovation and public trust in AI governance. Empirical assessment of coordination mechanisms between market surveillance authorities, notifying bodies, and sectoral regulators would address a critical gap in current understanding. Future research could examine information flows, decision-making processes, and procedural integration across institutional boundaries, potentially identifying best practices for effective coordination despite structural fragmentation. Finally, future studies should investigate how these different models perform in practice, particularly regarding their ability to meet the AI Act's requirements for expertise, independence, and effective oversight. This could include examining coordination mechanisms in fragmented systems, capacity building in new institutions, and the effectiveness of different approaches to balancing sectoral expertise with comprehensive oversight.

Submitted: 31 January 2025, Revised: 26 March 2025, Accepted: 21 April 2025, Published: 27 June 2025

Abstract This paper examines Artificial Intelligence (AI) implementation and evolution in the Brazilian judicial system from 2021 to 2023, focusing on institutional framework, governance, and applications. Analyzing data from the National Justice Council's (CNJ) AI project dashboards, we identified patterns in project development, survival rates, and categorical shifts in AI applications. Our findings reveal a 238% increase in AI projects, yet with a high mortality rate; over 65% were deprecated by 2023.

The research indicates an evolution from basic data classification applications towards more sophisticated uses like procedural intelligence and user-focused services. While initial projects targeted efficiency, newer ones demonstrate transformative potential, including novel mediation and fraud detection. The study also assesses the regulatory framework (CNJ Resolution n. 615/2025) and its adaptation to emerging technologies like generative AI. Despite progress, challenges persist in the coordinated development and strategic implementation of AI systems. The paper concludes with recommendations for enhancing cross-court collaboration, establishing impact-focused metrics, and monitoring the new regulatory framework to ensure AI improves efficiency, transparency, and access to Justice, while considering risks like algorithmic bias, data quality, and accountability. These findings also provide valuable insights for other judicial systems undertaking similar transformations, highlighting the need for strong governance and strategic coordination for a successful AI integration.

1. Introduction

Enhanced efficiency, transparency, and access to Justice drive the Brazilian Justice System's digital transformation. With a backlog of 83 million court cases, 99% in digital format (Brazil, CNJ, 2023), AI adoption was natural for task automation, data analysis, and informed decision-making, improving justice delivery speed and quality. The National Justice Council – CNJ plays a pivotal role in this transformation, especially in mapping and coordinating the implementation of AI and establishing guidelines to ensure trustworthy AI adoption by Brazilian courts.

Performing existing tasks faster through the use of AI certainly improves court efficiency and is desirable. Nonetheless, it is important to note that improving working practices using technology is only a partial enhancement. As highlighted by Susskind, technology can play a more relevant role: "It can displace and revolutionize conventional working habits—doing new things, rather than old things in new ways" (SUSSKIND, 2019). The primary challenge lies in enhancing civil litigation efficacy while ensuring equitable trial conditions for all stakeholders engaged in the process.

Therefore, it is crucial to understand how AI is being used in Brazilian Courts and whether it is being implemented to overcome inequalities, improve efficiency, transparency, and coherence, and consequently improve the quality of judicial service as a whole.

Despite potential benefits, AI use in the Judiciary presents risks and challenges. There are concerns about algorithmic bias, data quality, accountability, and the preservation of human judgment in judicial decision-making. Establishing robust governance frameworks and ethical standards is necessary to mitigate these risks and ensure

responsible AI deployment. The CNJ enacted Resolution n. 615 on March 11, 2025, superseding the previous one from 2020 with updated directives to address the evolving technological landscape, especially generative AI.

Since 2021, to advance AI Governance in Brazilian Courts, the CNJ, beyond regulation, has collected and publicly shared court AI project data via open dashboards. We analyze this data to assess CNJ's coordination of collaborative AI for judicial efficacy and explore AI's problem-solving applications and its impact on transparency and access to Justice.

This paper aims to comprehensively analyze the evolution of AI's implementation within the Brazilian Justice System, including its applications, benefits, and potential challenges.

2. Implementation and Adoption of AI in the Brazilian Judicial System

2.1 Institutional Context Shaping AI Systems

The institutional framework of the Brazilian judicial system profoundly impacts AI Systems formulation and execution. The legal system is based on civil law tradition, with an emphasis on codified statutes and laws, but it also integrates common law elements through binding precedents from higher courts. The precedent system started to be developed in 2008 to manage the immense volume of lawsuits that reflect the mass relationships in modern society. The CNJ Great Litigants dashboard shows that in 2024, 25% of the judicial cases involved big companies or the Government (repeat players). It means that a great percentage of Brazilian court backlogs are fundamentally low-value, high-volume cases with similar facts and legal issues; they are considered mass or repetitive litigation. In brief, according to the new rules, when superior courts identify this type of case proliferation, the court selects a leading case and suspends the proceedings in similar cases. Once the leading case is decided, it becomes a precedent that must be applied to the suspended and future similar cases.

This establishes a systematic milieu conducive to AI applications, as algorithms can be effectively trained utilizing established legal structures and precedents and analyzing similar cases.

This blended system raises concerns about the use of AI as decision-making support systems, because it can affect the judges' discretion and the fairness of the judicial process. There is a debate on whether these systems should replicate previous judicial decisions while allowing judges to maintain their freedom or if they should promote greater uniformity in decisions, respecting higher judicial precedents. This indicates that integrating AI could either constrain or enhance judicial discretion, depending on its design and implementation (CASIMIRO, 2024).

The hierarchical structure of the Brazilian Judiciary, with multiple levels of appeal, also influences AI adoption. AI tools can be deployed at different levels to address specific needs and challenges. The diversity in court types, sizes, and composition further influences AI adoption, as different courts may have varying needs and challenges that AI can address (BRASIL, CNJ, 2022) and different budgets to invest in technology.

The Brazilian judicial system comprises two main types of courts: legal and special courts, and both have two layers of appeal plus the Supreme Federal Court:

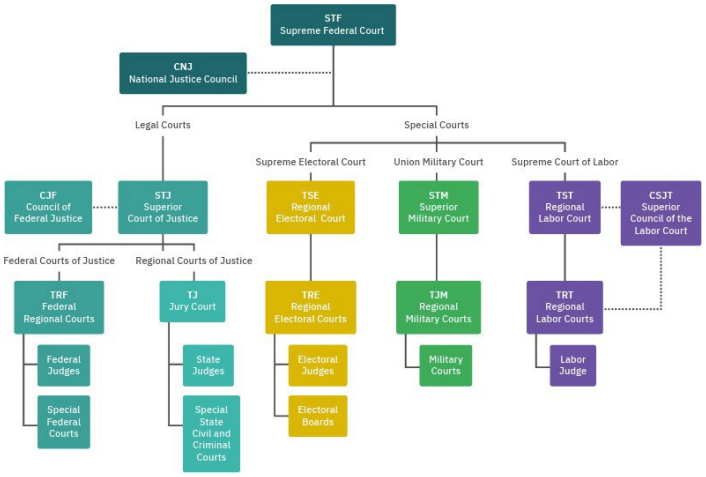

Fig. 1- Brazil, CNJ (2022).

Another important factor to consider is the enormous amount of digital legal data that has been produced for a long time. Electronic processes have been in Brazil since 2002 (Special Federal Courts), when courts introduced

digital case management systems. This trend was boosted in 2006 when the Law on digitizing judicial proceedings was enacted. Years later, in 2013, when more than 50 systems were in use by courts, the National Council of Justice established the Electronic Judicial Proceedings (PJe) as the official procedural tool. In 2015, the PJe Governance Network was created in an effort to unify the systems and facilitate communication among them. (Brazil. CNJ, 2022). Unfortunately, until now, the unification has not been accomplished, and other solutions are being studied and implemented to foster the systems communication, like the use of Application Programming Interface – API.

All this diversity led to an organic implementation of AI, and many courts were separately trying to solve the same problem by deploying different AI projects. In 2020, when the COVID-19 pandemic hit the courts and everything went virtual, the CNJ, in partnership with the United Nations Development Programme (UNDP), launched the Justice 4.0 Program – Innovation and Effectiveness in Achieving Justice for All, to coordinate better, foster collaboration and rationalize the human and material resources for the AI use in courts. The program is aligned with the United Nations Sustainable Development Goals (SDGs) 2030, especially the number 16, which includes the promotion of access to Justice for all.

It is worth mentioning three major initiatives of the program that aim to provide the infrastructure for the collaborative development of AI by courts, adopt the idea of Justice as a service, and promote data quality: the Judiciary's Digital Platform (PDPJ), the Synapses Platform, and the Codex Platform.

The Judiciary's Digital Platform (PDPJ) was launched in 2021, and its main objective is modernizing the Electronic Judicial Proceedings (PJe)transforming it into a multiservice system. It operates as a marketplace for justice services, enabling the courts to consume the functionalities created by other courts through APIs and permitting adaptations for their specific needs. The PDPJ is based on a central cloud infrastructure and fosters communication between the judicial services systems that are already in use within a unified and integrated platform, which includes other CNJ databases (Brazil, CNJ, 2022).

The Synapses Platform is an AI development and deployment platform, often referred to as an "AI Model Factory," that streamlines the delivery of AI models. It allows for creating AI microservices, which can be independently developed and integrated with various systems, especially the PJe. The platform provides an interface for supervised training of classification and text extraction models, which allows legal experts to curate and create new models tailored to specific legal needs. It also supports versioning of AI models, enabling model evolution tracking and maintaining multiple active versions. Hence, the platform facilitates the management and auditing of models in production, generating reports that detail their predictions and decision-making processes. This feature supports AI models' ethical and legal validation in the judicial environment. (Brasil, CNJ, 2019).

The Codex Platform consolidates procedural databases, providing textual content from documents and structured data. It serves as a repository of procedural information, accessible to a wide range of applications, such as producing business intelligence dashboards and reports, implementing intelligent and unified searches, and providing data for creating AI models.

On top of those platforms, the Datajud platform was created, a data lake that provides legal data from all Brazilian courts in real-time. It is the official source for the Brazilian justice statistics system. Based on the Datajud, the CNJ publishes regular court management and performance reports and maintains several dashboards. The Datajud was created in an open-source format that is accessible to the public in general, permitting researchers and anyone to audit the Courts' numbers. It contributes to developing judicial management tools based on evidence and enhancing transparency.

2.2 AI Governance in the Brazilian Judicial System

The governance of AI in Brazilian courts is a complex issue that interlaces technological innovation with ethical and regulatory challenges. While integrating AI into the Judiciary aims to enhance efficiency and precision in legal processes, it raises significant concerns regarding transparency, bias, and accountability.

In addition to the initiatives based on the Justice 4.0 Program described above, the CNJ also enacted in 2020 Resolution n. 322 to foster responsible artificial intelligence development and deployment in the Brazilian courts. Its primary objectives revolved around establishing principles and guidelines for the ethical and responsible integration of computational solutions aimed at enhancing process management and the overall effectiveness of judicial services. The structure of the Resolution was inspired by the principles proposed by the European Commission for the Efficiency of Justice – CEPEJ's ethical Charter (CEPEJ, 2018). Those principles are: i) the principle of respect for fundamental rights; ii) the principle of non-discrimination; iii) the principle of quality and security; iv) the principle of transparency, impartiality, and fairness; v) the principle of "under user control"; vi) the principle of accountability. Criticism of the Resolution n. 332/2020, relies on the difficulty of its enforcement and its inadequacy with the new technologies that have arrived.

With the objective of updating the regulatory framework for AI in the Judiciary, the CNJ enacted Resolution n. 615 on March 11, 2025, explicitly revoking Resolution n. 332/2020. The primary impetus behind this revision lies in the exponential growth and increasing sophistication of AI technologies, particularly generative AI, that are already being used in courts. This new Resolution introduces several key novelties and amendments designed to address these advancements' unique challenges and opportunities. The highlights are below.

The new Resolution brings the same principles as the old one, emphasizing human oversight's importance at all stages of AI development and use, particularly in decision-making processes. AI should serve as an auxiliary tool, and the judges retain full responsibility for their decisions. It also emphasizes data protection and security, requiring compliance with the Brazilian General Data Protection Law and adopting privacy by design and default principles. Data for training AI models must be representative, anonymized whenever possible, and subject to curation and monitoring.

Inspired by the European Artificial Intelligence Act (Europe, European Commission, 2024), it adopts a risk-based approach to categorize AI applications, with definitions of low-risk and high-risk categories placed in an annex to facilitate updating. The risk evaluation will consider factors such as the potential impact on fundamental rights, the complexity of the AI model, its financial sustainability, its intended and potential uses, and the amount of sensitive data it utilizes. It also forbids the Judiciary from developing or using AI solutions that pose excessive risks to information security, fundamental rights, or the independence of judges, especially those that 1) lack human oversight, 2) establish profiles for predicting crime or for supporting decisions in labor cases, 3) ranks individuals based on behavior or social status, and 4) uses biometrics to recognize emotions.

According to the annex of the Resolution, the following purposes and contexts for developing AI solutions are considered high risk: 1) identifying profiles and behavioral patterns of individuals or groups; 2) assessing the evidence suitability and value in court cases, mainly if it affects the final decision; 3) investigating, evaluating, classifying, and interpreting facts as crimes; 4) formulating conclusive judgments on the application of legal rules or precedents to specific sets of facts, 5) facial or biometric identification and authentication for monitoring the behavior of individuals, unless it is to confirm someone's identity or for justified public safety with strong safeguards and monitoring.

On the other hand, AI used for the following purposes is considered low risk: 1) performing routine procedural tasks or supporting judicial administration, like organizing documents and data; 2) finding patterns in past court decisions to help ensure consistency, but without replacing a judge's own review; 3) Providing judges with decision-making support through management reports and analyses using jurimetrics, as long as the AI does not make moral judgments; 4) producing supporting text to facilitate the drafting of judicial acts as long as the judge supervises and produces the final version of the document; 5) improving a previously performed human activity without changing the result; 6) doing statistical analysis for court policy, with human checks to avoid bias; 7) transcribing audio and video recordings, with a human reviewing the final transcript; 8) anonymizing documents.

Specific attention is given to Large Language Models (LLMs) and other GenAI systems, outlining their permitted use as auxiliary tools for management or decision support, preferably through corporate solutions offered by the court. Direct contracting by judges and staff is permitted under specific conditions, including mandatory training and restrictions on using sensitive data for unauthorized training or high-risk purposes.

To foster governance, the Resolution establishes a National Committee for Judicial Artificial Intelligence with a plural composition to oversee and implement the guidelines. It promotes transparency through clear indicators and public reports on AI usage. It especially requires algorithmic impact assessments for high-risk solutions, which must be made public in summary form.

Also, the Resolution establishes mandatory continuous curation and monitoring mechanisms, with provisions for corrective measures or discontinuation of AI solutions in case of discriminatory bias or non-compliance.

The Sinapses platform remains the repository for registering AI solutions, respecting intellectual property, and eliminating the need to deposit large databases. AI models must, when technically possible, have explainable mechanisms, allowing judicial operators to understand and audit their decisions and operations.

The Resolution encourages collaboration between judicial bodies in the development and sharing of AI solutions while maintaining the courts' autonomy.

Regulating new technologies whose applications are not fully understood presents a significant challenge; however, this new Resolution marks an important step towards governing the use of AI in the courts, effectively balancing innovation with the essential principles of ethics, transparency, security, and the protection of fundamental rights.

In the following sessions we describe the methodology and proceed to the analysis of the courts' AI data considering both the institutional context and the new AI regulation.

3. Methodology

3.1. Dataset

To analyze the survival of projects in the Brazilian Judiciary, we downloaded consolidated data from the dashboards

Dashboards and data available at: https://www.cnj.jus.br/sistemas/plataforma-sinapses/paineis-e-publicacoes/ of the artificial intelligence research conducted by the National Justice Council - CNJ. These dashboards compile questionnaires sent to courts about the use, development, and implementation of AI projects in the Judiciary.

After downloading the data corresponding to the compiled results for each year in .csv files, we manually inspected them to identify data quality issues. Some cleaning steps were performed, such as removing records of projects unrelated to AI, records that simply denied the existence of AI in that category and duplicate records. To enable comparison, we also standardized the project names, which had slight variations between years.

After cleaning the data, we merged everything into a single table and added a field identifying the year of origin.

The fields in the consolidated table are:

ID → Unique identifier

Year → Reference year of the project

Court → Name of the court where the project was implemented or developed

Project → Name of the Project

Description → Description of the Project

3.2. Data Processing

Since our goal is to understand project mortality, we need to determine which projects existed and which ceased to exist. To achieve this, we created three fields:

- has_2021, has_2022, has_2023 → indicating whether the project existed in each year.

Next, we created an algorithm to ensure each project had a single entry, avoiding duplicate rows for the same project in different years. The algorithm works as follows:

- If a project has not yet been processed for a given court, check whether it appears in each analyzed year.

- Assign True or False for each year accordingly.

This structure enables easy visualization of each project's timeline and facilitates the mortality study. We can see the mortality results in the graphs displayed in the use cases section.

3.3. Classification

Once the data was prepared, we took a sample from 2023 and manually classified it based on the framework created by Suriani in a preview study regarding AI project categories in the Brazilian Judiciary and explained in the following session (SURIANI, 2022).

We used this labeled dataset as a seed to create a classifier using an LLM with GPT-4o-mini. In the prompt, we:

- Described each category

- Provided two examples for each

- Instructed the model to classify each case sequentially

The model was instructed to return its response in JSON format with two fields:

- Class → The assigned category

- Reasoning → Explanation for debugging and improving classification results

After classification, we generated the same mortality chart for the following year, enabling comparison.

4. AI Use Cases in Brazilian Courts

The Brazilian Judiciary handles a substantial volume of cases (83 million), primarily processed electronically (99%), with a considerable percentage classified as mass or repetitive litigation (25%). A distinctive characteristic of mass litigation is the factual and/or legal similarity of the underlying issues, which allows for identifying patterns for classification and grouping. The major success of artificial intelligence in Law has been achieved through data-based models that identify and correlate patterns to infer outcomes. These computational models have enough input to develop enormously in the Brazilian legal market. More recently, the development of large language models has innovated AI applications in Brazilian courts. The CNJ has been collecting data on the court's AI Projects since 2021 and publishing them on dashboards. Using the data available on the dashboards, we proceeded to analyze the evolution of AI projects, especially considering what kind of problem the use of AI in courts wants to solve.

To better understand the projects and compare them over time, we used a framework that is anchored on five categories, according to each project's objectives: (i) classification and grouping of procedural data; (ii) procedural intelligence; (iii) case law organization and decision drafting; (iv) service/communication with parties, lawyers or court staff; (v) others. (SURIANI, 2022)

The majority of the legal data produced by court systems is not structured data. Therefore, not surprisingly, a significant number of AI projects are focused on data categorization and clustering functionalities. This category includes, for example, projects aiming to identify and classify legal issues, find documents and case file similarities, perform triage, and operate legal indexing.

Once the data is organized, it is possible to evolve into more complex AI models that aim to improve the efficiency of the case course procedures. Those projects, for example, suggest the appropriate procedural steps, facilitate procedural decision-making, help manage the case flow, automate procedural tasks, and accelerate the case progress. Those are what we call procedural intelligence AI projects. They are especially important in the enforcement phase of the legal procedure, as it is one of the greatest bottlenecks in the Brazilian caseload.

These two categories of projects normally increase courts' efficiency, leveraging technology to accomplish faster and sometimes more accurately what courts' assistants would take longer to achieve. Surveys show that the main barriers to access to the Brazilian courts are the perception that legal proceedings are slow, expensive, and complex (RAMOS, 2021). Thus, those kinds of projects help overcome the time and cost barriers to access to Justice.

Moving to the third category, the case law organization and decision drafting AI models help judges to understand the norms and precedents that may apply to the cases, supporting decision-making. Some AI models suggest or generate decision drafts once the correct rule or precedent is identified. More recently, with generative AI, some projects also aim to assist legal writing. Those projects help the courts achieve consistency and transparency on top of increasing efficiency. However, this kind of project might need a better understanding of the responsible use of AI and its ethical considerations, especially the interference with the judge's discretion and procedural fairness.

Finally, some projects seek to assist internal and external users of the legal system. They often use chatbots or other interfaces to answer procedural queries, provide and receive cases or legal information, and facilitate and simplify communication through the use of plain language and other legal design tools. These projects focus on user needs and mainly contribute to helping lay people through procedural complexities. It's an innovative way to interact with and serve citizens.

Some of the projects have more specific objectives that are not related to the above categorization, they are categorized as *others*. For example, projects that apply facial recognition for security reasons in the courts, and that predict the likelihood of revictimization in domestic violence cases to support public policies.

4.1 AI projects survival

As seen before, AI projects have arisen organically, and the CNJ is putting a lot of effort into changing this scenario to foster the collaborative development and deployment of AI and to rationalize the human and material resources for AI use in courts.

The data shows evidence that a potentially high level of experimentation may still be happening during this initial period of AI expansion. The vast majority of the projects launched during the analyzed period are already deprecated. Between 2021 and 2022, 145 projects were created, and on average, 50% of the projects survived at least 1 year, and 35% survived the entire period.

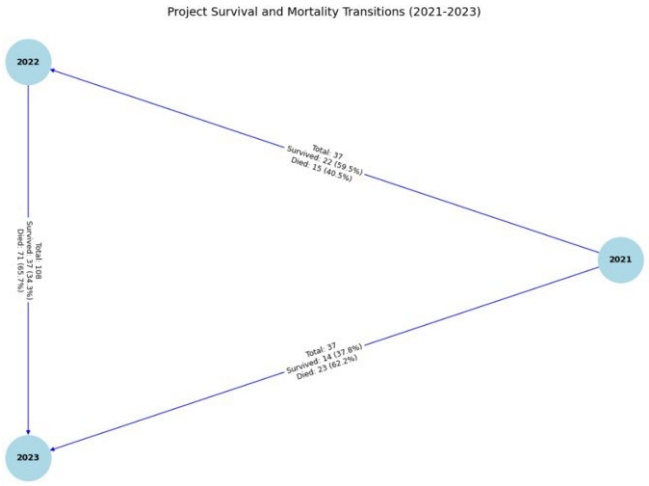

Fig. 2 – Survival and Mortality Transitions

The number of AI projects had a steep increase in the period, with a staggering rate of 238% since 2021. Also relevant, the number of projects that were shut down substantially increased. At the end of 2023, over 65% of projects created were deprecated. In other words, despite the substantial increase in the number of AI projects that could indicate clear progress on AI deployment in courts, two-thirds of those active in 2022 were short-lived. This may indicate high experimentation and a lack of a coordinated guideline roadmap for innovation.

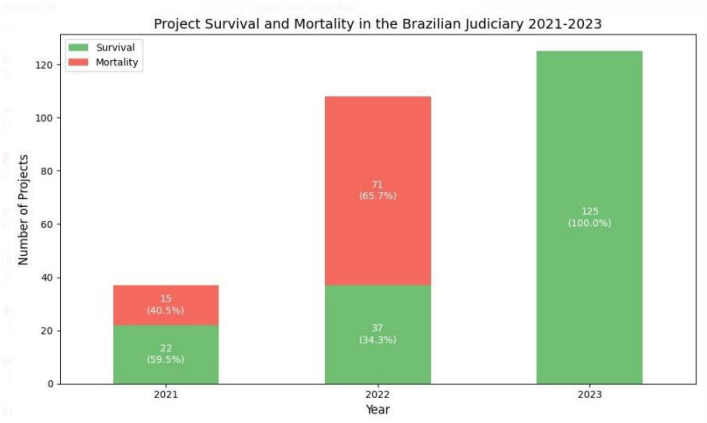

Fig. 3 – Survival and Mortality of AI Projects

4.2 Evolution by category

When looking at the data by category (Fig. 4), it is possible to see that the majority of AI projects were developed within the category Classification and grouping of procedural data. That might indicate that the foundation for an AI-based solution starts with the organization and classification of data, so it makes sense to see more projects aiming that at this initial phase of AI expansion. As we can see in Fig. 5, over time, the prevalence of this type of project is declining while other types are becoming more significant. This might show that, once the data classification problem is being solved, this is becoming less important, bringing more opportunities for developing more analytical types of projects. Another possibility is that AI models are becoming more sophisticated and require less data organization.

Procedural Intelligence projects come in second place in terms of representativeness. This shows a potential interest in going beyond data organization (a more short-term solution) towards an analytical focus. This has a much more direct impact on the efficiency of courts, delivering faster judicial service to citizens.

On the other hand, more strategic initiatives to, for example, improve the understanding of Brazilian jurisprudence, which can help enhance the legal system's cohesion and transparency, are still lagging, with only 29 out of the 210 projects falling in this category.

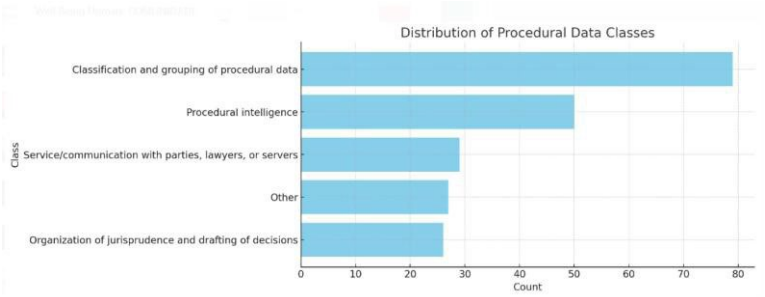

Fig. 4 – number of AI projects by category

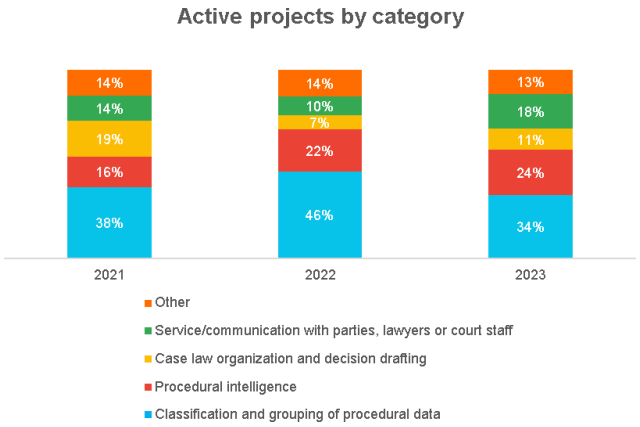

Fig. 5 – AI projects by category overtime

Looking specifically into the four main categories (Fig. 6), it is also clear that all projects are increasing, in absolute terms, when comparing 2023 with 2021. However, one of the categories (Classification) declined in 2023, reinforcing the hypothesis raised above that the need for data classification is becoming less relevant – either because it has been solved or because the AI models do not need organized data to perform, especially the LLM-based AI models.

It is also important to highlight that, despite a relative decline in the period (from 19% to 11%—Fig 5), projects aiming to organize caselaw and decision drafting saw a significant increase in absolute numbers, going from 7 to 14 in 2023 (Fig 6).

Also, regarding absolute numbers, the two categories with the most significant increase of initiatives over time, increasing 5 times in the period, were service/communication with parties and procedure intelligence. The one that increased the least, 2 times in the period, was the case law organization and decision drafting. According to Resolution CNJ 615/25, this type of initiative can be considered of higher risk, requiring a more conservative approach to its development, which may be one of the reasons for the lower rates of increase compared to other lower-risk categories.

It is important to consider that the consistent use of predictive systems, even when presented as recommendations, may make it progressively harder for judges to justify deviating from them. This is due to technological bias, the inclination to believe that algorithmic outputs are inherently more accurate and impartial than human reasoning. This situation also presents ethical challenges. If judges regularly rely on predictive system recommendations to justify their rulings, it subtly alters accountability and responsibility, shifting it from the judge to the systems and their developers. Moreover, if private entities create predictive systems, the privatization of judicial decision-making, as noted by Surden, becomes a potential problem (SURDEN, 2019).

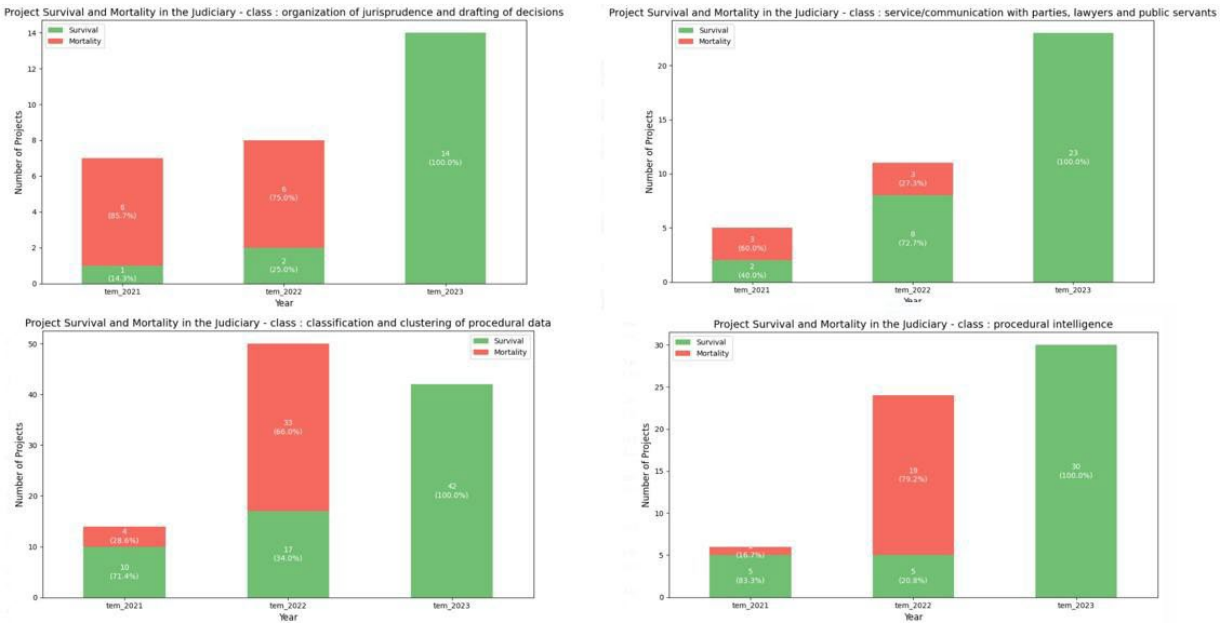

Fig. 6 – AI projects by category and mortality overtime

In 2023, new types of projects that bring an innovative way to manage conflicts have risen. More specifically, five new projects focused on identifying cases with higher chances of being resolved through mediation. Those cases are then directed to mediators for a consensual solution instead of following the regular judicial procedure. Also, there are five projects focused on identifying fraud and/or abuse of litigants who try to take advantage of the system in borderline situations and end up bloating the Judiciary. According to Resolution 615/25, those projects will probably be considered high-risk.

The report "Mapping AI risks within the Brazilian Judiciary" (Relatório de Pesquisa: mapeando riscos da IA no Poder Judiciário brasileiro) (CABALLERO et al., 2024) analyzed the projects active in the 2023 dashboard and suggests that 65% of them will probably be considered of low risk, around 18% will be considered of high risk, and 1% will be considered of excessive risk. Around 16% are inconclusive.

Finally, highlighting the increasing use of GenAI, five projects reported its application in 2023. A recent CNJ survey indicates widespread adoption of GenAI by judges and their assistants, with 50% of respondents having used it and approximately 30% of that group employing it in jurisdictional tasks (Brasil, CNJ, 2024).

Resolution 615 established that when GenAI is used to help draft a judicial act, the judge may mention this in the body of the decision. However, it must be automatically recorded in the court's internal system for tracking data, checking how it is being used, and for possible future review. It will be a huge challenge, though, to track the diffuse use of GenAI when the court's systems do not provide it and if it is being used in a responsible way.

When the National Committee for Judicial Artificial Intelligence starts implementing Resolution 615/25, we will have more clarity and data for further investigation on this issue.

5. Conclusion

The implementation of AI in Brazilian courts is rapidly progressing; however, this quick expansion has also been less organized than expected, potentially hindering the development of a more structured and strategic approach to AI implementation. The high experimentation rate and lack of a coordinated guideline or roadmap for innovation have led to a significant number of short-lived AI projects.

Also, several challenges persist. Despite the CNJ's efforts to promote collaboration through initiatives like the Justice 4.0 Program, the Synapses Platform, and the PDPJ, AI projects' organic and somewhat fragmented development indicates a need for stronger coordination and strategic alignment. The current regulatory framework, established by Resolution n. 615/2025, while providing critical ethical guidelines, brings updates to address emerging technologies, particularly generative AI, and to establish more effective enforcement mechanisms.

Establishing clear and relevant success metrics for AI projects in the Brazilian justice system is a crucial aspect that needs careful consideration. The evolving landscape can be misleading and give a false sense of progress if the

primary metric is only the number of AI-related projects. While the increase in AI projects indicates growing interest and investment, it does not necessarily translate into meaningful impact or improvement in the justice system.

As the Brazilian AI landscape progresses, three key areas require attention: first, establishing more robust cross-court collaboration and resource-sharing mechanisms to reduce redundant efforts and promote more sustainable AI implementations. Second, developing clear success metrics that go beyond project counts to measure the actual impact on judicial efficiency and access to Justice. Third, the implementation of the new regulatory framework must be monitored because it will be challenging to address emerging technologies better while maintaining the balance between innovation and ethical considerations. Ongoing monitoring, evaluation, and adaptation of AI governance frameworks will be essential to ensure that AI serves as a tool for enhancing justice delivery and promoting equitable outcomes for all stakeholders.

The Brazilian Judiciary's experience with AI implementation offers valuable lessons for other judicial systems undertaking similar digital transformations. It demonstrates that successful AI integration requires not only technological capability but also strong governance frameworks, strategic coordination, and a clear focus on sustainable, impactful solutions rather than short-term experimentation.

Track 3: Data-Driven Services in Government for Evidence-Based Policy and Public Value

Track Description

The Data-Driven Services in Government track aims to investigate how public sectors can complement services and policies through Information and Communication Technologies (ICTs) and various forms of data, such as open data, big data, and linked data. The track aimed to gather papers exploring the interactions of data application, data governance, and/or data policy. More specifically, it aimed to (i) examine the relationship between data and evidence-based policy formulation and execution; (ii) the impact of data on various types of policies at all levels of government, including health policy, social policy, water use policy, energy policy, and more; and (iii) a view on data-driven services for public value creation from various angles: the sectoral view, user view, stakeholder view, and more. Evidence-based Policy means creating, applying, and assessing policies and social programs based on the most reliable and relevant evidence available. It emphasizes making decisions grounded in current social and behavioral science research and promotes proven interventions. Creating value from government data and services is particularly important to many stakeholders, including governments, the private sector, and citizens.

Submitted: 31 January 2025, Revised: 26 March 2025, Accepted: 21 April 2025, Published: 30 June 2025

Abstract. This study introduces a multidimensional framework designed to assess Digital Public Service Quality (PS-DigQual) within e-government systems. The proposed framework integrates three pivotal dimensions: System Quality (QSt), Operation Quality (QOp), and Information Quality (QInf). QSt ensures a robust technical foundation through infrastructure reliability, navigability, and compliance with accessibility standards. QOp focuses on responsiveness, personalization, and user support to enhance service delivery. QInf emphasizes transparency, accuracy, and the timely availability of information, thereby fostering trust and accountability. Addressing gaps in traditional models such as SERVQUAL and E-S-QUAL, the framework adapts to the unique requirements of public digital services, where transparency, inclusion, and citizen engagement are critical. The research methodology is grounded in a systematic literature review and bibliometric analysis, spanning publications from 1990 to January 2025. This approach ensures a comprehensive theoretical foundation and identifies critical gaps in existing frameworks. The study further applies the PS-DigQual framework in practical scenarios, demonstrating that improvements in one dimension positively impact others, creating a cycle of continuous enhancement. Key contributions include a scalable analytical tool for policymakers and a robust foundation for further academic inquiry. The framework's adaptability allows it to be tailored across different cultural and institutional contexts, with the potential for incorporating emerging technologies such as artificial intelligence and blockchain. By promoting efficiency, transparency, and inclusion, PS-DigQual represents a significant advancement in evaluating and improving digital public services. The study concludes with suggestions for future research, emphasizing the development of measurement scales and strategies to ensure sustainable public value in the digital era.

1. Introduction

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Digital transformation in the public sector, enabled by e-government (e-gov), has reconfigured the paradigms of public administration. By transforming governmental processes, e-government enhances operational efficiency, promotes transparency, and fosters citizen engagement, thereby creating a new interaction model between governments and society (Janssen & van der Voort, 2020; Mergel et al., 2019). The success of these initiatives depends on the adoption of appropriate frameworks to assess and ensure the quality of digital services.

Traditional quality frameworks, such as SERVQUAL and E-S-QUAL, have been widely employed to measure service quality across various private sector contexts. However, studies indicate that these models fail to address critical dimensions required for the evaluation of digital public services, such as transparency, democratic participation, and accountability (Fernandes et al., 2020; Lampeão, 2023). These gaps are concerning, as they undermine the effectiveness of digital service quality measurement in the public sector, hindering the development of public policies aimed at meeting the growing demands for digital inclusion and responsiveness (Santos & Souza, 2021).

Traditional quality frameworks, such as SERVQUAL and E-S-QUAL, have been widely employed to measure service quality across various private sector contexts. However, when applied to the e-government milieu, these models exhibit distinct limitations. Specifically, E-S-QUAL, although adapted for electronic services, prioritizes consumer-centric indicators such as efficiency and reliability, while neglecting essential public sector attributes like transparency, civic engagement, and the ethical use of information (Ahmed et al., 2020; Çelik, 2021). For example, E-S-QUAL does not adequately capture the need for participatory mechanisms or the public value generated by open data initiatives, both of which are central to digital governance. Consequently, the indicators currently utilized in these models may fail to accurately gauge the multidimensional quality expected in public digital services, particularly in contexts where accountability and inclusiveness are paramount.

In the public sector, the complexity and interdependence of technology, processes, and governance render existing approaches insufficient for evaluating quality in e-government. Traditional models overlook key elements of the public sphere, such as the social impact of digital services and their capacity to meaningfully engage citizens. Furthermore, there is a lack of frameworks that integrate technical, social, and informational dimensions to meet the evolving demands of public administrations operating in a digital environment.

This article proposes a multidimensional conceptual framework for evaluating Digital Public Service Quality (PS-DigQual), structured around three interdependent dimensions: System Quality (QSt), Operation Quality (QOp), and Information Quality (QInf). The model addresses theoretical and practical gaps by providing an analytical foundation that combines technical principles with social demands, thereby promoting both efficiency and digital inclusion.

The objective of this study is to develop and validate a multidimensional framework for assessing the quality of digital public services within e-government systems. To guide this endeavor, the following research questions are posed: (1) What are the critical dimensions that define digital public service quality in the context of e-government? (2) How do existing quality models fall short in addressing the unique requirements of public digital services? (3) In what ways can the proposed framework enhance the evaluation and continuous improvement of digital public services, considering diverse sociotechnical and institutional contexts?

The structure of the article is organized into five main sections. Following this introduction, the Theoretical Foundation section presents the theories and existing frameworks that support the proposed model. The Methodology section details the systematic review approach used to develop the framework. The Framework section introduces and discusses the core dimensions and their interrelations. Finally, the article concludes with a section on Contributions and Future Research, highlighting the study's key insights and suggesting avenues for further investigation.

2. Theoretical Framework

This section presents the fundamental concepts related to quality in e-government, as well as the existing challenges and gaps. It discusses the limitations of traditional frameworks for evaluating digital public services and highlights the need for a multidimensional model that integrates technical, social, and informational dimensions, aligning with the specific demands of the public sector.

2.1. Quality in e-Government

E-government requires balancing technical efficiency with transparency, digital inclusion, and social responsiveness, demanding models tailored to the public sector's unique context (Meijer & Bekkers, 2015; Haug,

Dan & Mergel, 2024). While most frameworks stem from Western research, recent studies from Asia, Africa, and Latin America highlight additional challenges, such as digital literacy gaps, infrastructure disparities, and the influence of local governance (Alhassan et al., 2022; Chen et al., 2023; Souza & Silva, 2021). For example, South Korea and Singapore focus on digital identity integration, while Kenya and Brazil address access barriers and community engagement. These diverse perspectives enrich the theoretical basis for digital public service quality and emphasize the need for adaptable frameworks.

The DeLone and McLean Information Success Model (2003) is foundational, proposing System Quality, Information Quality, and Service Quality as key, interacting dimensions for evaluating user satisfaction and organizational outcomes. System Quality ensures robust, secure, and accessible platforms, reducing failures and building trust (Teo et al., 2009). However, usability and navigability are also vital for digital inclusion, especially for users with limited skills or access.

Information Quality, as defined by DeLone and McLean (2003), supports decision-making and interaction by ensuring data is clear, accurate, and timely, which strengthens transparency and accountability—crucial for public trust (Zaidi & Qteishat, 2012). Service Quality relies on robust systems and reliable information, enabling responsive and personalized services, especially important for real-time or high-demand situations (Teo, 2020).

These dimensions are interdependent. Strong technical infrastructure enables rapid, accurate information processing, supporting responsive services and fostering public trust, which drives continuous improvement (Lindgren et al., 2019). Transparency, closely tied to Information and Service Quality, ensures citizens understand data use and have access to reliable information. However, the emphasis on democratic values like transparency and participation varies by context, sometimes conflicting with efficiency or New Public Management principles.

The PS-DigQual framework addresses these nuances, allowing flexible integration of democratic principles according to local priorities and cultures, thus remaining relevant across diverse environments and supporting both efficiency and inclusive governance. Digital inclusion cuts across all dimensions, ensuring accessibility for all citizens and promoting equity and participation (Teo, 2020; Zuiderwijk et al., 2021).

In sum, the interdependence of these dimensions highlights the need for integrative approaches in e-government, as reliable systems and information enhance service quality, engagement, and trust, ultimately generating sustainable public value (DeLone & McLean, 2003; Zaidi & Qteishat, 2012). Quality in e-government must be operationalized in an integrated way to foster efficiency, transparency, and citizen engagement.

2.2. Integration of Dimensions and Operationalization in E-Government

The Digital Public Service Quality (PS-DigQual) Framework adopts a multidimensional approach, addressing gaps in traditional models by incorporating the specific needs of the digital public sector. Transparency and accountability are fundamental for evaluating digital public services, fostering trust and citizen engagement (Miller & Sanders, 2023). Integrating these elements into assessment frameworks strengthens governmental accountability and ensures digital services are more responsive to citizens' needs (Torres, Pina & Acerete, 2024).

Unlike traditional models focused on technical and relational aspects of the private sector, PS-DigQual broadens the perspective by including transparency, digital inclusion, and accountability. These elements reflect core public governance values and highlight the need for greater interaction between technology, information, and citizens. The framework links technical robustness, information reliability, and user experience, showing how these interdependencies generate public value.

The integration of System Quality (QSt), Information Quality (QInf), and Operation Quality (QOp) forms a framework that aligns technical, informational, and relational aspects with demands for transparency, responsiveness, and accountability (Janowski et al., 2018; Lindgren et al., 2019; Miller & Sanders, 2023; Torres et al., 2024). Grounded in Sociotechnical Systems Theory, it emphasizes the interdependence of technology, processes, and users (Trist, 1981). Recent frameworks also stress the need for transparency and accountability to enhance trust and engagement.

QSt is the technical foundation, covering Robust Infrastructure, Navigability, Accessibility, and Security. These ensure stable, inclusive, and secure platforms, supporting high traffic and protecting data (Yang et al., 2019; Zuiderwijk et al., 2021). Metrics like response time and accessibility standards ensure the infrastructure supports services and citizen interaction, underpinning QInf and QOp.

QInf centers on Transparency, Accuracy, and Relevance, ensuring data is clear, reliable, and useful. Transparent information boosts accountability, while accuracy reduces ambiguities. Operationalization includes clarity, real-

time updates, and data in multiple formats (Meijer & Bekkers, 2015; Cucciniello et al., 2019). Digital inclusion, linked to QSt, ensures marginalized groups can access services (Teo, 2020; Zuiderwijk et al., 2021).

QOp focuses on the interaction between systems and citizens, including Support, Efficiency, Responsiveness, and Personalization. Unlike SERVQUAL, the model values the government's ability to meet demands in a personalized, agile way. Responsiveness measures issue resolution speed, while Personalization assesses adaptation to user needs (Panagiotopoulos et al., 2019).

Integrating these dimensions is critical. QSt enables efficient, responsive services; QInf builds trust through accurate information; and their synergy, supported by iterative evaluation, drives continuous improvement in e-government (Lindgren et al., 2019; Cordella & Paletti, 2019).To consolidate the differences between the proposed PS-DigQual framework and existing models, Table 1 presents a comparative analysis, highlighting the gaps in traditional models and demonstrating how the proposed framework comprehensively addresses essential aspects of e-government. This includes the integration of technical, informational, and social dimensions, which are either overlooked or inadequately addressed by previous approaches.

Table 1. Comparative Analysis: Proposed Framework vs. Traditional Models

Dimension	**COBRA**	**SERVQUAL**	**E-S-QUAL**	**Miller & Sanders (2023)**	**Torres et al. (2024)**	**Other Frameworks**	**Proposed Framework**
System Quality	Does not directly address technical infrastructure but includes cost-benefit analysis.	Partially addresses technical reliability without focusing on infrastructure.	Emphasizes usability and security, but limited to the e-commerce context.	Emphasizes robust and secure infrastructure to support essential public services and minimize technical risks.	Focuses on scalability and technical resilience to promote inclusion and trust, aligned with digital accountability.	Examples: GovQual, TAM – Focus on flexibility and technical efficiency in systems.	Integrates robust infrastructure, universal accessibility, and technical security with digital inclusion.
Operation Quality	Focus on cost-benefit, risk, and opportunity for user satisfaction.	Based on responsiveness, empathy, and reliability in the private sector.	Evaluation based on efficiency and reliability without considering citizen responsiveness.	Emphasizes responsiveness and personalization as means to maximize the impact of digital public services.	Adopts metrics to measure responsiveness and support as a foundation for accountability and citizen engagement.	GovQual and other models include reliability and technical user support.	Focuses on citizen support, operational efficiency, and responsiveness in the public context.
Information Quality	Explores accuracy and relevance without explicit focus on transparency.	Addresses information quality in a limited manner, focusing on user perception.	Focuses on information quality as support for e-commerce.	Transparency as a central pillar, linked to data clarity and ethical information usage.	Prioritizes transparency and information accessibility as tools for citizen engagement and trust.	Models like TAM emphasize accuracy, relevance, and information usability.	Centers transparency and accountability as essential for public trust and citizen engagement.

ences	et al., (2014); Weera kkody et al., (2013)	n et al., (1988); Papadomich elaki & Mentzas, (2009)	et al., (2005); Zeithaml et al., (2002)	Sanders, R. (2023)	Pina, V., & Acerete, B. (2024)	(2009); Papadomich elaki & Mentzas, (2012); Venkatesh et al., (2003)	(2019); Lindgren et al., (2019); Panagiotopo ulos et al., (2019)

Source: Research Data

Table demonstrates that System Quality (QSt) is insufficiently addressed by traditional models. COBRA and SERVQUAL do not directly explore technical infrastructure, while E-S-QUAL focuses on usability and security but is limited to the context of e-commerce. In contrast, the frameworks proposed by Miller and Sanders (2023) and Torres et al. (2024) take a step forward by emphasizing the need for technical resilience, scalability, and support for digital inclusion in public services. The proposed framework builds on these recent approaches, further broadening the scope by integrating robust infrastructure, universal accessibility, and technical security while considering digital inclusion as a cross-cutting aspect. This approach addresses the specific demands of the digital public sector by ensuring resilient, accessible systems that align with the transparency and accountability required in contemporary e-government.

In the dimension of Operation Quality (QOp), traditional models focus on factors such as cost-benefit, responsiveness, and empathy—typical characteristics of the private sector. E-S-QUAL, for example, evaluates efficiency but overlooks the citizen responsiveness required in e-government. Conversely, the frameworks by Miller and Sanders (2023) and Torres et al. (2024) make significant contributions by emphasizing personalization and responsiveness as mechanisms to strengthen trust and accountability in public services. The proposed framework complements these approaches by prioritizing citizen support, operational efficiency, and responsiveness, aligning with the requirements of the public sector, where trust and engagement are essential. This evolution is noteworthy as it treats the user not merely as a customer but as an active participant in the delivery of digital services.

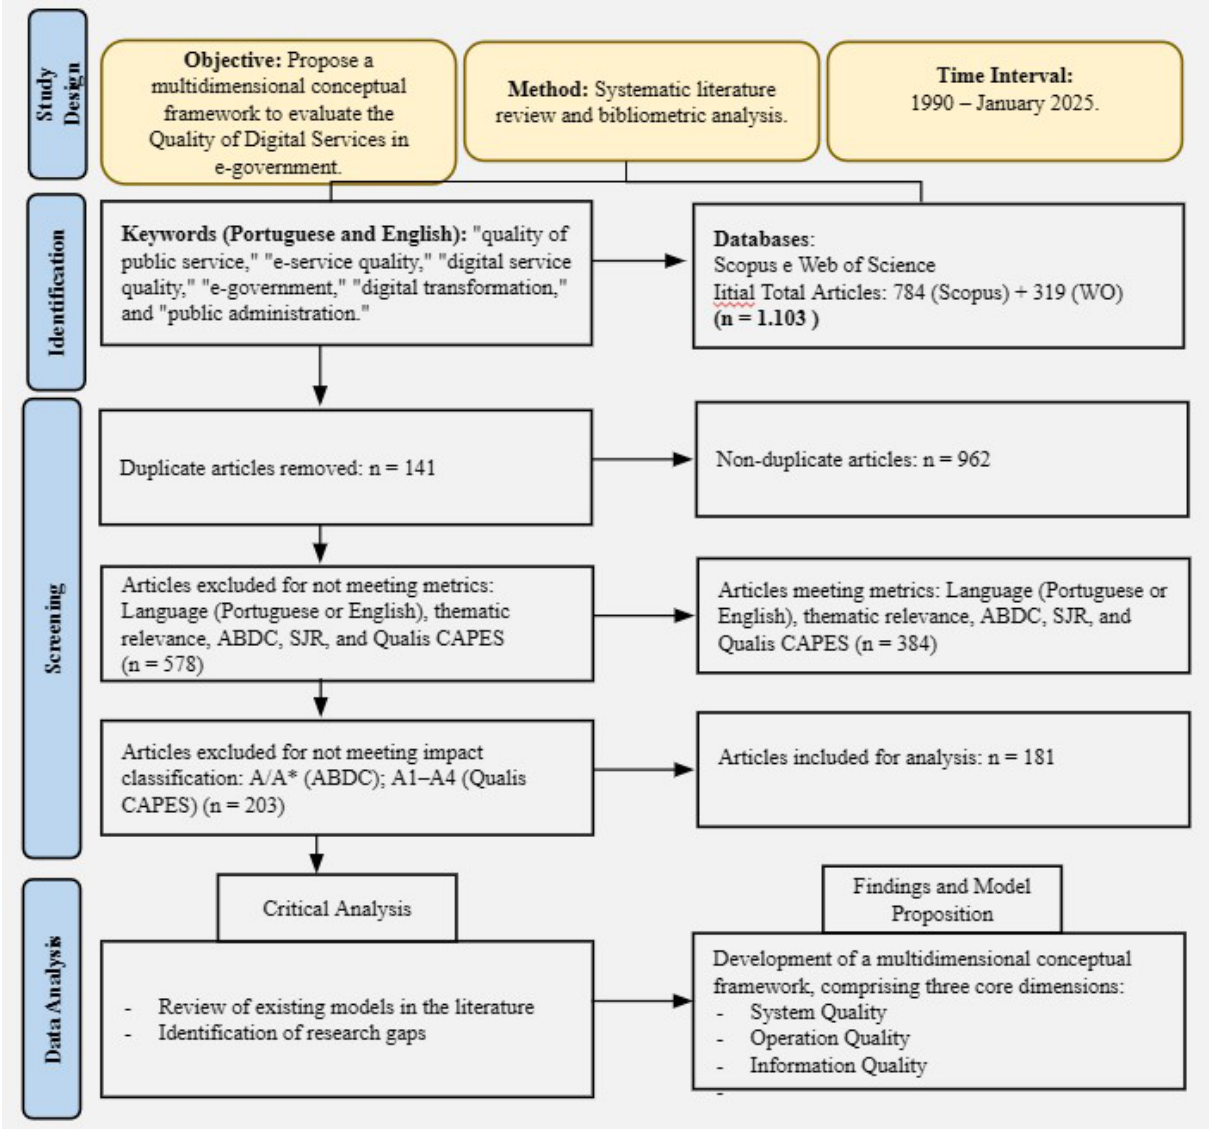
The analysis of Information Quality (QInf) reveals that models such as COBRA and SERVQUAL address accuracy and relevance but overlook transparency and accountability—critical elements for e-government. The frameworks by Miller and Sanders (2023) and Torres et al. (2024) place transparency at the center, linking it to data clarity and ethical information usage. The proposed framework goes further by centralizing transparency and accountability as essential components for fostering public trust and citizen engagement. This reinforces the role of clear, reliable, and verifiable information in digital governance, highlighting its interdependence with other dimensions.

In conclusion, the proposed framework addresses the gaps in traditional models by offering a holistic view of quality in digital public services. Its practical application extends beyond academic analysis, providing public managers with a structured tool to diagnose strengths and weaknesses in digital service delivery. For instance, by systematically evaluating system robustness, information transparency, and operational responsiveness, policymakers can identify targeted interventions to enhance user experience and foster greater citizen trust.

Additionally, the framework supports benchmarking across different governmental units and facilitates the monitoring of progress over time, thereby informing strategic decisions and resource allocation in digital transformation initiatives.

3. Method

To support the proposal of a multidimensional conceptual framework for evaluating the quality of digital services in e-government, a systematic literature review with a bibliometric approach was conducted. The selection protocol, while rigorous, adopted strict inclusion and exclusion criteria to ensure the relevance and quality of the analyzed studies.



However, this narrow focus may have inadvertently excluded pertinent research, particularly studies published in non-English languages or in regional journals not indexed in major databases. This limitation suggests that some relevant perspectives, especially from emerging economies or underrepresented regions, may not have been fully captured. Future research should consider expanding the scope of the review to include a broader array of sources, thereby enriching the analysis and enhancing the global applicability of the proposed framework.

By integrating both quantitative and qualitative analyses, as well as tools such as the Bibliometrix package in RStudio and manual validations, the SLR-4 model identifies trends, gaps, and provides a robust foundation for discussions and future recommendations, directly contributing to the study's objectives. This approach is particularly suitable for fields such as e-government, which require integrative analyses to capture theoretical

advancements, identify emerging trends, and explore gaps in the literature.

The chosen methodology ensures methodological rigor, a comprehensive and detailed overview of the state of the art in the field, and reliable outcomes for guiding future research (Tranfield, Denyer & Smart, 2003; Kitchenham, 2004; Donthu et al., 2021). Figure 1 illustrates the research design followed in this study.

Figure 1: Research Design

Source: Prepared by the authors (2025)

Once the research objective and method were defined—outlined in the first stage presented in Figure 1 (Study Design)— 1990 to January 2025 was established. The next phase, referred to as Identification, involved the following steps:

Definition of keywords: Terms in both English and Portuguese were selected to cover three main areas: digital public service quality, e-government, and emerging technologies.

Database search: The search was conducted in the Scopus and Web of Science databases, resulting in the initial identification of 1,103 articles. This process was carried out at the end of the second semester of 2024.

Additionally, the search strings were constructed using Boolean operators to combine the keywords and ensure precision in article retrieval. The search in the Scopus database was conducted as follows: (TITLE-ABS-KEY("qualidade do serviço público" OR "quality of public service" OR "service quality" OR "public service efficiency" OR "public service delivery" OR "e-service quality" OR "digital service quality") AND (TITLE-ABS-KEY("e-government" OR "e-gov" OR "digital government" OR "e-government services" OR "digital transformation"

OR "inovação tecnológica" OR "technological innovation" OR "tecnologias da informação" OR "information technology" OR "ICT" OR "TIC" OR "digital governance" OR "information systems" OR "interoperability")) AND (TITLE-ABS-KEY("setor público" OR "public sector" OR "administração pública" OR "public administration" OR "serviço público" OR "public service" OR "gestão pública" OR "public management")) AND (LIMIT-TO(DOCTYPE, "ar") OR LIMIT-TO(DOCTYPE, "re")). Na Web of Science, a estratégia de busca foi: TS=("quality of public service" OR "service quality" OR "public service efficiency" OR "public service delivery" OR "e-service quality" OR "digital service quality") AND TS=("e-government" OR "digital government" OR "e-government services" OR "digital transformation" OR "technological innovation" OR "information technology" OR "ICT" OR "digital governance" OR "information systems" OR "interoperability") AND TS=("public sector" OR "public administration" OR "public service" OR "public management") AND (LIMIT-TO(DOCTYPE, "article") OR LIMIT-TO(DOCTYPE, "review")).

The screening phase involved the removal of duplicates, language criteria, thematic relevance, academic quality metrics, and impact classification. A total of 141 duplicate articles were removed, and the remaining documents were initially screened based on language (English and Portuguese), thematic relevance, and recognized academic metrics such as the Australian Business Deans Council (ABDC), SCImago Journal Rank (SJR), and Qualis CAPES. As a result, 578 articles were excluded, leaving 384 studies for further analysis.

The selection of ABDC, SJR, and Qualis CAPES as metrics serves as a benchmark for classifying journals according to their academic quality: ABDC is one of the main indicators in the field of management (ABDC, 2022), SJR measures the visibility and impact of scientific journals by considering both the number of citations and the quality of the citing articles, making it a reliable indicator of international research impact (SJR, 2023) and Qualis CAPES is a Brazilian system for evaluating academic production, used to assess the quality of journals across various fields of knowledge. The choice of these metrics was essential to ensure that the study relied on high-quality literature. By combining these metrics, the study encompasses both international academic quality and relevant regional indicators.

Further in the screening process, 203 articles not classified by impact (A/A* in ABDC and A1–A4 in Qualis CAPES) were excluded, resulting in 181 articles. The impact classification reflects the decision to prioritize articles published in high-impact and highly relevant journals, which are more likely to contain robust theoretical and methodological approaches and significant contributions to advancing knowledge in the studied field.

The data analysis phase involved a critical review of the 181 selected articles, which, through a meticulous reading process, enabled the identification and study of existing models on service quality and digital service quality in the literature, as well as the identification of research gaps in this field. This process provided the foundation for recognizing three key dimensions: System Quality, Operation Quality, and Information Quality. These dimensions were critical in the development of the multidimensional conceptual framework, the central objective of this study.

Since the main focus of this research is the proposition of the conceptual model, which was made possible by preliminary analyses, including bibliometric analysis, detailed results of these analyses are not presented. Instead, the description and discussion of the proposed multidimensional conceptual framework are prioritized. However, it is worth noting that preliminary analyses using the Bibliometrix package in R Studio generated keyword co-occurrence maps, collaboration networks, and temporal evolution charts, which provided valuable insights for developing the framework.

These preliminary analyses played a crucial role by offering a comprehensive view of trends and gaps in the literature, guiding the construction of the proposed model. Additionally, they helped to theoretically support the key dimensions that comprise the framework, ensuring its relevance and alignment with the current needs of the field of study.

4. Proposed Framework for Digital Public Service Quality (PS-DigQual)

The PS-DigQual Framework is an integrated structure developed to assess and enhance the quality of digital public services in the context of e-government.

4.1. General Structure of the Framework

Grounded in the core dimensions of System Quality (QSt), Operation Quality (QOp), and Information Quality (QInf), the framework combines technical, relational, and informational aspects to address the complexities of the digital public sector. This multidimensional approach ensures transparency, inclusion, and efficiency in an increasingly challenging digital governance environment (Mergel et al., 2019; Lindgren et al., 2019).

Figure 2 integrates the three dimensions, illustrating how each contributes to the overall quality of e-government services:

QSt (System Quality) provides the necessary technical infrastructure.

QOp (Operation Quality) focuses on responsiveness and personalized citizen service.

QInf (Information Quality) ensures the transparency and clarity of the information provided.

The interaction between these dimensions fosters public trust, citizen engagement, and sustainable public value.

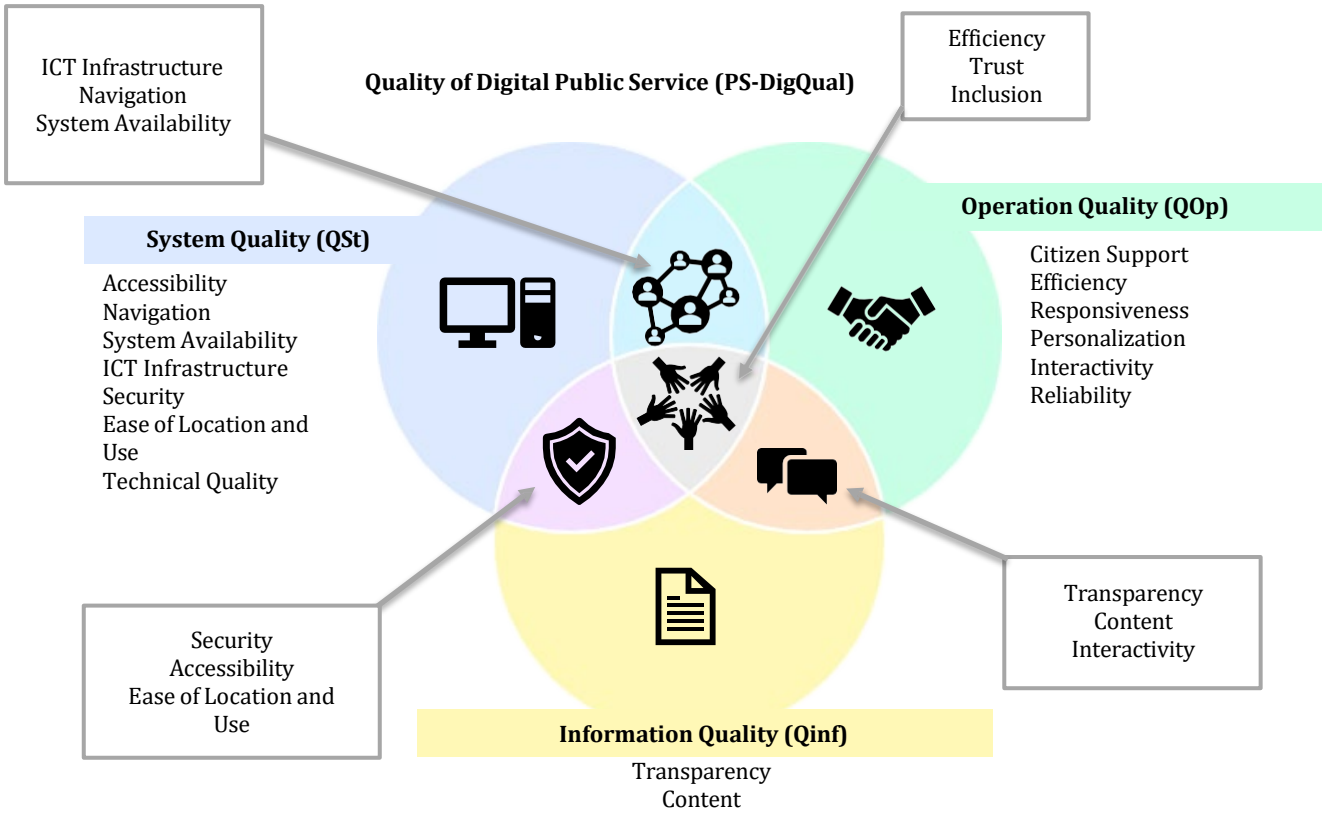


Figure 2. Quality of Digital Public Service Framework
Source: Research Data

The intersections between the dimensions reflect relationships and synergies that underpin the framework's effectiveness. The technical robustness of QSt ensures stability and security, supporting the transparency and informational accessibility of QInf. Simultaneously, this reliable information strengthens citizen trust and makes personalized support, part of QOp, more efficient (Panagiotopoulos et al., 2019; Cucciniello et al., 2019; Miller & Sanders, 2023; Torres et al., 2024). Additionally, frameworks proposed by Lindgren et al. (2019) and Mergel et al. (2019) emphasize the importance of integrating technical, relational, and informational dimensions to promote greater digital inclusion and accountability in public digital services.

The ultimate goal of the framework is achieved at the intersection of the dimensions, represented by Efficiency, Trust, and Inclusion. This centrality reflects the ambition to foster a robust and responsive e-government, where reliable systems, clear information, and interactive services work together to maximize public impact. This approach integrates the principles of Sociotechnical Systems Theory, which highlights the importance of dynamic interactions between technology, citizens, and public institutions (Trist, 1981; Janowski et al., 2018).

Moreover, the framework addresses gaps identified in traditional models, such as SERVQUAL and E-S-QUAL, by adapting to the specificities of the digital public sector. Although widely used, these models fail to capture critical elements such as transparency, digital inclusion, and governmental accountability. The multidimensional integration proposed in the framework addresses these limitations, offering a robust foundation for the continuous

evaluation and improvement of public digital services (Twizeyimana & Andersson, 2019).

The overall structure of the framework also responds to the growing need for more inclusive and efficient digital governance. Platforms such as GOV.UK and Gov.br can directly benefit from this approach by using the metrics associated with each dimension to continuously monitor and adjust their services. This adaptability makes the framework a valuable tool for public managers seeking to align digital transformation with the demands and expectations of contemporary society (Cordella & Paletti, 2019).

In summary, the PS-DigQual Framework represents a significant contribution to both the practice and theory of e-government. Its ability to integrate technical, informational, and service dimensions into a cohesive model provides not only a basis for quality evaluation but also a strategic guide for innovation and continuous improvement in the digital public sector. This framework establishes a more comprehensive analytical paradigm for public governance, aligning with the demands for efficiency, trust, and inclusion (Lindgren et al., 2019; Yang et al., 2019).

4.2. Detailed Description of Core Dimensions

The following section discusses the core dimensions of the PS-DigQual Framework and the specific components that support e-government quality. Each dimension—QSt, QInf, and QOp—is analyzed in terms of its relevance and impact on the delivery of digital services. This approach fosters a comprehensive evaluation based on quality metrics.

4.2.1. System Quality

System Quality (QSt) is the technical pillar of the framework, providing the necessary foundation for the efficient and secure operation of public digital services. Components such as robust infrastructure, intuitive navigability, accessibility, and technical security ensure that systems can support high user volumes, promoting a reliable and inclusive experience (Zuiderwijk et al., 2021; Panagiotopoulos et al., 2019; Medaglia et al., 2024).

Robust Infrastructure is essential to meet large-scale demands, particularly for digital services accessed by millions of citizens simultaneously. Studies by Klievink et al. (2017), Janowski et al. (2018), and Bassey (2022) emphasize that resilient and scalable systems not only handle high traffic volumes but also ensure the integrity and continuity of operations, even in critical scenarios. This robustness is crucial for enabling integration with other framework dimensions.

Intuitive Navigability and Accessibility play key roles in promoting digital inclusion. Platforms adhering to accessibility standards, such as WCAG, ensure that individuals with varying abilities or technological limitations can effectively interact with public services. This approach broadens access and enhances the user experience, especially for vulnerable groups, aligning with the recommendations of Lindgren et al. (2019), Medaglia, Rukanova & Zhang (2024), and Cordella & Paletti (2019).

Technical Security is indispensable for safeguarding sensitive data and enhancing public trust by ensuring information integrity in digital environments. Secure systems prevent data breaches and cyberattacks, which can undermine platform credibility. Security is a critical element for ensuring the sustainability and continued adoption of e-government services, particularly in high-risk and complex contexts (Yang et al., 2019; Wirtz et al., 2022; Bassey, 2022).

4.2.2. Information Quality

Information Quality (QInf) is a central element of the framework, aimed at promoting governmental transparency and strengthening citizen engagement. Clear, accurate, and accessible information ensures that citizens understand government actions, fostering accountability and public trust. The reliability of information is critical to sustaining the legitimacy of public institutions and promoting responsive and transparent governance (Meijer & Bekkers, 2015; Cucciniello et al., 2019; Medaglia, 2024).

In the context of e-government, QInf goes beyond merely providing data; it encompasses characteristics such as relevance, clarity, and real-time updates. These attributes ensure that users have access to reliable and useful data, enabling meaningful interactions with public digital services. Meijer and Bekkers (2015) and Janowski et al. (2018) emphasize the connection between informational reliability and active citizen participation, promoting engagement in decision-making processes.

Transparency is an indispensable component for accountability and legitimacy in e-government. It guarantees that

decisions, processes, and data are accessible and understandable, promoting inclusive and trustworthy governance (Batini et al., 2009; Twizeyimana & Andersson, 2019; Medaglia, 2024). Clarity, accuracy, and relevance are equally essential for building public trust: clarity facilitates understanding, accuracy eliminates ambiguities, and relevance ensures that the data meets citizens' needs (Panagiotopoulos et al., 2019; Lindgren et al., 2019; Medaglia, 2024).

These components create a positive cycle, where reliable information fosters greater citizen engagement and governmental legitimacy. This holistic approach reinforces the interdependence between informational transparency and the operational effectiveness of public services. In this way, e-government becomes a more inclusive and accessible environment, aligned with contemporary demands for accountability and digital inclusion (Osman et al., 2014; Lindgren et al., 2019; Cucciniello et al., 2019; Teo, 2020).

To assess QInf, key metrics such as textual clarity, real-time updates, and accessibility in multiple formats are fundamental. Textual clarity facilitates user understanding of data, while frequent updates strengthen the perception of governmental responsiveness (Cucciniello et al., 2019; Meijer & Bekkers, 2015). In turn, accessibility in diverse formats meets the needs of different citizen profiles, promoting digital inclusion and democratic participation (Lindgren et al., 2019; Janowski et al., 2018).

Supported by transparency and robust metrics, QInf is crucial for establishing a reliable and efficient e-government. It ensures that citizens have access to dependable information and strengthens their ability to actively participate in decision-making processes, thereby promoting accountability and continuous engagement (Panagiotopoulos et al., 2019; Twizeyimana & Andersson, 2019; Medaglia et al., 2024).

4.2.3. Operation Quality

Operation Quality (QOp) is a crucial dimension of the framework, directly addressing citizens' needs through responsive and effective digital services. Its implementation ensures interactive and personalized support, fostering continuous engagement and strengthening public trust (Panagiotopoulos et al., 2019; Meijer & Bekkers, 2015). Studies indicate that a well-structured QOp significantly enhances user satisfaction and reinforces the legitimacy of public institutions (Cucciniello et al., 2019; Lindgren et al., 2019). This dimension emphasizes the ability of digital services to adapt to specific citizen demands by offering quick and efficient solutions. Key components such as Citizen Support, Personalization, and Operational Efficiency are fundamental pillars for aligning services with user expectations (Yang et al., 2019; Cordella & Paletti, 2019). Platforms integrating technical and informational support help eliminate access barriers and promote a meaningful and inclusive citizen experience (Meijer & Bekkers, 2015; Panagiotopoulos et al., 2019).

Citizen Support plays a central role by providing immediate and effective assistance, meeting user needs promptly. This approach strengthens trust in e-government, creating a positive perception of public management (Lindgren et al., 2019; Cucciniello et al., 2019). Additionally, Personalization allows services to be tailored to users' specific needs, improving citizen engagement and fostering a sense of digital inclusion (Cordella & Paletti, 2019; Yang et al., 2019). Operational Efficiency complements these efforts by minimizing delays and ensuring reliable service delivery. Robust infrastructures and automated processes optimize response time, reducing costs and operational errors (Zuiderwijk et al., 2021; Klievink et al., 2017).

The integration of personalization and efficiency results in more accessible digital services, enhancing the perception of reliability. Metrics are essential for measuring the effectiveness of QOp. Resolution Time indicates how quickly requests are addressed, while Satisfaction Levels reflect users' perceptions regarding the clarity, personalization, and responsiveness of the service—critical factors for public trust (Panagiotopoulos et al., 2019; Cucciniello et al., 2019).

Tools such as Net Promoter Score (NPS) and Repeat Usage Rate provide insights into user retention and service impact. Combined metrics help managers continuously adjust digital services, promoting continuous improvement cycles and ensuring that citizen demands are met efficiently and inclusively (Lindgren et al., 2019; Yang et al., 2019).

4.3. Framework Contributions

The operationalization of the proposed framework enables its practical and strategic application in contemporary digital government platforms, such as GOV.UK and Gov.br. This model systematizes the evaluation of the dimensions QSt, QOp, and QInf, fostering alignment between administrative efficiency, digital inclusion, and governmental transparency. This multidimensional approach contributes to more responsive and participatory

governance (Medaglia et al., 2024; Schmitz, 2023).

The implementation of the framework involves the application of both qualitative and quantitative metrics. On Gov.br, metrics such as latency and technical stability evaluate system robustness, while on GOV.UK, indicators such as textual clarity and informational updates promote citizen engagement. Technological advances enable the integration of real-time monitoring systems that measure user satisfaction, resolution times, and compliance with accessibility standards. These iterative development practices allow for dynamic data-driven adjustments, resulting in greater responsiveness and operational efficiency. Longitudinal studies corroborate the effectiveness of these practices in strengthening citizen trust and improving public digital services (Yang et al., 2019; Zuiderwijk et al., 2021; Medaglia et al., 2024).

The adaptability of the framework stands out in different e-government contexts. Strategies focused on personalization and reliability improve the user experience on GOV.UK, while Gov.br leverages the dimensional intersections to foster digital inclusion and governmental transparency. These synergies, supported by recent studies, emphasize the importance of integrating technology, processes, and governance to maximize public value (Lindgren et al., 2019; Panagiotopoulos et al., 2019; Twizeyimana & Andersson, 2019).

The framework's operationalization addresses gaps in traditional models and contributes to the creation of more responsive and inclusive public digital services. Its multidimensional approach reinforces the interdependence between quality pillars, demonstrating how robust infrastructure supports personalized services, while enhanced transparency promotes accountability and public trust—an essential integration given the demands of the digital public sector.

The proposed framework addresses significant gaps in traditional models such as SERVQUAL and E-S-QUAL by integrating critical dimensions of transparency, digital inclusion, and citizen support. Conventional models often overlook these characteristics, which are fundamental in the e-government context, where accountability and responsiveness are indispensable for fostering public trust and institutional legitimacy (Mergel et al., 2019; Medaglia et al., 2024). The integration of these dimensions also responds to the growing demand for inclusive and accessible digital services.

By articulating QSt, QOp, and QInf, the framework provides a holistic approach to the evaluation and improvement of digital services. Multidimensional frameworks enhance the capacity to align technical capabilities with citizen needs, promoting more effective, responsive, and accessible services (Lindgren et al., 2019; Schmitz & Wimmer, 2023).

For public managers, the framework serves as a strategic tool, reinforcing citizen trust through transparent governmental processes. Clear and accessible information, supported by robust systems, is crucial for consolidating trust in public institutions. According to Cucciniello et al. (2019) and Medaglia et al. (2024), digital platforms that prioritize clarity and informational reliability promote both engagement and accountability.

Promoting digital inclusion is another direct benefit of the framework. By adhering to accessibility standards and ensuring intuitive navigability, the model ensures that all citizens, regardless of their limitations, can access and utilize digital services. This inclusive focus addresses the growing need for equitable and socially responsive governance, as emphasized by Panagiotopoulos et al. (2019) and Schmitz & Wimmer (2023).

Operational efficiency is improved through the integration of the framework's technical and social dimensions. Robust infrastructures minimize failures and reduce response times, while personalized services significantly enhance the user experience. Studies by Yang et al. (2019) and Lindgren et al. (2022) show that interdependent systems, such as those proposed, enhance operational agility and reduce costs, benefiting both citizens and institutions.

Finally, the framework contributes to responsiveness by offering tools for monitoring and continuous service adjustments. Aligned with the principles of adaptive governance, this iterative approach allows public managers to respond to citizen demands with agility and precision. Meijer and Bekkers (2015) and Medaglia et al. (2024) highlight that monitoring practices and metrics-based adjustments increase the perception of institutional efficiency and legitimacy.

The implementation of the framework addresses structural and functional gaps, promoting inclusive, efficient, and responsive governance. By consolidating citizen trust and optimizing digital services, the model aligns with contemporary demands for public value and digital transformation in the public sector.

Despite the contributions of this study, several limitations must be acknowledged. The reliance on a systematic literature review with a narrowly defined protocol may have restricted the diversity of perspectives included in

the analysis. Additionally, the framework has not yet been empirically tested in a wide range of governmental contexts, which may limit its generalizability. Future research should seek to validate the framework through case studies and comparative analyses, as well as to incorporate feedback from practitioners and citizens to further refine its dimensions and indicators.

5. Conclusion

This study proposes a multidimensional conceptual framework for evaluating the quality of digital services in the e-government context, integrating technical, informational, and service dimensions. The research highlights the importance of models that consider technical robustness while addressing transparency and citizen participation as central components for the success of inclusive and effective public digital services.

The application of the framework demonstrates how improvements in one dimension can positively influence other areas, fostering a virtuous cycle of enhancement. This model addresses gaps identified in previous frameworks by offering an integrative and scalable approach to digital service evaluation, aligning with contemporary demands for responsiveness and accountability in the public sector.

The contributions of this work span both theory and practice, providing a foundation for future research and for public managers seeking to optimize the delivery of digital services. Additionally, the practical implications of the framework include its ability to guide strategic decision-making in e-government, promoting efficiency, inclusion, and sustainable public value.

The existence of a valid and consistent model for evaluating digital services offered by public entities is essential, serving as a means for citizens to directly assess the quality of the services provided. Various digital government regulations in different countries advocate for the evaluation and monitoring of services as a means of ensuring transparency and social participation. However, the lack of a specific framework for evaluating public digital service quality, as initially proposed in this study, has led to the use of tools that are poorly adapted to the unique characteristics of such services.

The proposed approach in PS-DigQual links key elements related to system, operation, and information, which are essential for evaluating public digital service quality. This approach enhances the development of metrics and scales for assessing e-government outcomes, contributing to the continuous improvement of services provided to citizens.

Future research could explore the integration of emerging technologies, such as artificial intelligence and blockchain, into the PS-DigQual framework to automate and enhance the evaluation of digital public service quality. Additionally, comparative studies across different countries and administrative cultures would provide valuable insights into the adaptability and impact of the framework. Researchers are also encouraged to develop and validate measurement scales for each dimension, as well as to investigate the relationship between digital service quality and broader outcomes such as public trust, social inclusion, and sustainable public value.

Abstract. The effective use of evidence is crucial for improving public sector programmes' design, implementation, and outcomes, particularly in addressing the complex challenges developing countries like South Africa face. Outcome 8 of the National Development Plan (NDP), which aims to transform human settlements and improve the quality of life for South African citizens, has been the subject of multiple evaluations since its introduction in 2010. Despite the availability of extensive evaluation data, integrating findings into policy and practice has often been inconsistent, with recurring issues identified across various evaluation cycles. This study systematically reviews the factors affecting the use of evidence generated from these evaluations in Outcome 8 programmes, specifically focusing on evaluations conducted from 2010 to the present. The review synthesizes government evaluations, policy reports, and academic literature to identify key barriers and facilitators in using evidence for policy-making and programme implementation. The findings reveal several barriers to evidence use, including political interference, which often influences the prioritization and implementation of evidence-based policies; limited capacity within government departments, hindering the interpretation and application of evaluation findings; and challenges in data consistency across national, provincial, and local government levels. Additionally, the review identifies that public sector programmes often rely predominantly on quantitative metrics, which may overlook the value of qualitative insights that could offer more context and a deeper understanding of policy impacts and outcomes. On the other hand, facilitators of evidence use, such as establishing strong institutional frameworks, forming evidence networks to promote knowledge exchange, and enhancing collaboration between evaluators and policymakers, were also highlighted. These facilitators help create an environment where evidence is more likely to inform policy decisions, leading to more effective governance and better programme outcomes. The review concludes by recommending strategies to address these barriers and improve the integration of evidence into policy-making and programme implementation. Key recommendations include strengthening the capacity of public sector officials to interpret and apply evaluation findings, promoting collaboration between evaluators and policymakers, and institutionalizing the use of evidence across government departments. Overcoming these challenges is crucial for improving the effectiveness of Outcome 8 programmes, advancing the broader goals of human settlement transformation in South Africa, and enhancing the impact of public policies.

1. Introduction and background

Evidence-based policymaking (EBPM) is a vital governance approach that emphasizes the systematic use of data and evaluation findings in the design and implementation of public policies. The core objective of EBPM is to ensure that policy decisions are made based on solid empirical evidence, as opposed to being influenced by political

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

pressures, ideology, or conjecture [1; 2]. This approach is grounded in the idea that public policies should be informed by expert knowledge and responsive to real-world data and research outcomes. EBPM aims to improve policy efficiency, effectiveness, and equity by aligning decisions with the best available evidence [3; 4]. As the global trend towards data-driven governance continues, the focus on evidence as a key driver of policy formulation and implementation has gained momentum, particularly in addressing socio-economic challenges in developing countries like South Africa [5; 6]. This strategy is intended to help governments make informed choices that ultimately improve public service delivery and citizen well-being, ensuring that resources are allocated efficiently to the most needed areas.

In South Africa, the application of EBPM has been institutionalized in recent years as part of the government's efforts to address socio-economic challenges, especially in the post-apartheid era. The government has recognized the value of utilizing evidence to guide decision-making processes, which is reflected in the establishment of various frameworks, such as the National Evaluation Policy Framework (NEPF) and the National Development Plan (NDP) [7; 8]. The NDP, introduced in 2010, serves as a long-term blueprint for transforming South Africa's socio-economic landscape, with a clear emphasis on using evidence to tackle the country's most pressing issues, including poverty, inequality, and unemployment [8]. While these frameworks are designed to guide evidence integration, their implementation has often faced significant challenges, particularly in translating the insights from evaluations into tangible policy changes [9; 10]. The evidence generated by government evaluations is crucial in this context, as it informs the continuous improvement of public sector programmes, yet its full potential remains underutilized in policy and programme execution.

Outcome 8 of the NDP, which focuses on transforming human settlements, has been the subject of numerous evaluations aimed at assessing the success of various interventions designed to address South Africa's housing crisis. This outcome aims to reduce the country's significant housing backlog, improve the quality of housing stock, and ensure that marginalized communities have access to sustainable living environments [8]. Several key programmes have been implemented under Outcome 8, including the Upgrading of Informal Settlements Programme (UISP), the Emergency Housing Programme (EHP), Rural Housing Programmes, the Enhanced People's Housing Process (EPHP), and the Integrated Residential Development Programme (IRDP) [11; 12]. These initiatives are central to addressing the housing needs of South Africa's growing population, particularly in underserved areas. While evaluations of these programmes have generated considerable evidence on their successes and shortcomings, the findings have not always been integrated into policy decisions, leading to inefficiencies in programme implementation [13; 9]. Despite the existence of frameworks intended to promote the use of evidence, these evaluations have identified recurring issues, including delays in housing delivery, insufficient infrastructure development, and inadequate service provision, that have yet to be fully addressed.

The motivation for this study arises from recognizing that despite multiple evaluations, the same findings continue to emerge across the various Outcome 8 programmes. The repeated nature of these findings suggests systemic issues in the way evaluations are conducted and how their findings are integrated into subsequent policymaking. The lack of effective translation of evaluation results into policy adjustments has led to the persistence of challenges that undermine the impact of Outcome 8 programmes. Several key evaluation reports from the Department of Human Settlements (DHS) and the Department of Planning, Monitoring and Evaluation (DPME) have documented these findings across various evaluation cycles. Yet, the effectiveness of policy adjustments based on these findings has been inconsistent. For example, despite identifying problems such as inadequate coordination between national, provincial, and local authorities, many evaluations found that these issues were not sufficiently addressed in follow-up programmes [11; 9]. This issue underscores the need for a more comprehensive understanding of why evidence is not fully integrated into policymaking.

The core problem this study seeks to address is the persistent gap between the evaluation findings and their integration into policy and practice, specifically within Outcome 8 programmes of South Africa's National Development Plan. Despite multiple evaluations conducted on these programmes since 2013, evidence generated from these assessments has not been consistently translated into actionable policy. The lack of a systematic and institutionalized approach to utilizing evaluation results means that valuable insights are often overlooked or underutilized, preventing the programmes from reaching their full potential in transforming human settlements. This study examines this disconnect and aims to identify the systemic barriers preventing the effective use of evaluation evidence. The table below summarises recurring findings across various Outcome 8 evaluation reports, highlighting the repeated issues that continue to hinder progress despite the availability of evaluation data. These

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

findings underscore the need for a deeper exploration of the factors that prevent evidence from driving meaningful change in public policy and programme outcomes.

Table 1: Summary of Recurring Findings Across Various Outcome 8 Evaluation Reports

Evaluation Report	Recurring Findings Identified	Year(s) of Recurrence	Evaluation Report
DHS, 2013: Monitoring, Evaluation and Impact Assessment Framework	Inconsistent implementation of recommendations, poor interdepartmental coordination	2013, 2016, 2019	DHS, 2013: Monitoring, Evaluation and Impact Assessment Framework [11]
DHS, 2014: Rapid Appraisal of Outcome 8	Delayed housing delivery, lack of clear policy implementation framework	2014, 2017, 2021	DHS, 2014: Rapid Appraisal of Outcome 8 [12]
DHS, 2016: Impact Evaluation of Affordable Housing Approaches	Data collection inconsistencies, gaps in tracking programme beneficiaries	2016, 2019, 2023	DHS, 2016: Impact Evaluation of Affordable Housing Approaches [13]
DPME, 2017: National Evaluation Plan Review	Ineffective oversight mechanisms, lack of actionable policy integration	2017, 2018, 2020	DPME, 2017: National Evaluation Plan Review [9]
DHS, 2019: Performance Evaluation of Outcome 8 Programmes	Inconsistent policy application, inadequate monitoring systems	2019, 2021, 2023	DHS, 2019: Performance Evaluation of Outcome 8 Programmes [14]
DHS, 2021: Baseline Evaluation of Informal Settlements Upgrading	Lack of community participation, incomplete baseline data	2021, 2023	DHS, 2021: Baseline Evaluation of Informal Settlements Upgrading [15]
Goldman et al., 2015: Evaluation of Evidence Utilization in Housing Policy	Minimal use of evaluation findings for policy change	2015, 2018, 2021	Goldman et al., 2015: Evaluation of Evidence Utilization in Housing Policy [16]

The current study aims to address this critical gap by investigating the factors that prevent the systematic and consistent use of evidence in policymaking for Outcome 8 programmes. Specifically, the study seeks to explore the institutional, political, and organizational dynamics that contribute to the underutilization of evaluation findings, focusing on identifying the barriers that hinder evidence use and the enablers that could facilitate better integration. By thoroughly examining these factors, the study aims to provide actionable insights into how these recurring issues can be addressed, thereby enhancing the overall effectiveness of Outcome 8 programmes. Ultimately, the study aspires to contribute to the broader objectives of human settlement transformation in South Africa, supporting the achievement of sustainable, inclusive, and impactful development outcomes in the housing and human settlements sector.

The structure of this paper is organized into several key sections to ensure a comprehensive analysis of the factors affecting the use of evidence from evaluations in Outcome 8 programmes in South Africa. Following this introduction and background, the second section outlines the methodology, detailing the systematic review approach, selection criteria for documents, and the sources of evidence, which include government evaluations, policy reports, and academic literature. The third section presents the findings from the review, identifying the key barriers and facilitators to using evidence in Outcome 8 programmes, focusing on political, institutional, and organizational factors. The fourth section provides a detailed discussion of these findings, exploring how these factors impact the integration of evaluation results into policy and practice and how the relationship between evaluators and policymakers influences evidence use. Finally, the conclusion summarizes the main findings, reflects on their broader implications for public governance in South Africa, and suggests areas for further research

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

to improve the use of evidence in public sector programmes. The paper will integrate references to key literature, and government reports to support the analysis and provide context for the discussion.

2. Methodology

This study employs a systematic review methodology to investigate the factors influencing the use of evidence in public sector programmes, with a specific focus on Outcome 8 under South Africa's NDP. Outcome 8 is a critical case study for examining how evaluation findings are utilized in policy-making and programme implementation. A systematic review is a widely recognized research method that synthesizes evidence from multiple sources to provide a structured and objective analysis of a specific research problem [17]. This approach is particularly suited for this study as it identifies, selects, synthesises, and interprets existing evaluations, policy reports, and academic literature related to using evidence in Outcome 8 programmes. The review follows the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) framework, which provides a transparent and rigorous process for conducting systematic reviews [18]. The primary objective of this systematic review is to explore the factors that enable or hinder the effective integration of evaluation findings into public sector decision-making, with a specific focus on the human settlement programmes under Outcome 8.

By adopting Outcome 8 as a case study, the research examines how evidence from evaluations conducted between 2010 and 2024 has influenced policy and programme implementation in South Africa's housing and human settlement sector. The systematic review process involved multiple stages: data collection, eligibility screening, thematic synthesis, and interpretation. Key government evaluation reports, grey literature, and peer-reviewed academic studies were analyzed to determine recurring themes related to evidence use. A thematic analysis was applied to categorize emerging themes, ensuring that both conceptual and empirical insights were captured. This study provides a comprehensive and in-depth analysis of the systemic factors affecting the use of evidence in public governance, particularly emphasising the challenges and opportunities within Outcome 8 programmes. The findings will contribute to the broader discourse on EBPM in South Africa and other developing countries, where similar governance and policy implementation challenges persist.

2.1 Emergent question

The research is guided by the following core question: *What factors influence the use of evidence in public sector programmes, with a specific case study of Outcome 8 under South Africa's NDP?* This question addressed a critical gap in the literature on EBPM in the South African public sector. While evaluations play an essential role in shaping policy, their integration into real-world policy decisions remains inconsistent. Focusing on Outcome 8 as a case study, the review seeks to identify the systemic, institutional, political, and operational factors determining whether evaluation findings are utilized or disregarded in policy-making. The study aims to provide insights into the mechanisms that enhance evidence use and those that act as obstacles, ultimately informing strategies to improve the uptake of evaluation findings in public governance.

2.2 Search strategy

To ensure the review was methodologically rigorous and comprehensive, searches were conducted across multiple academic databases and institutional repositories to include both peer-reviewed academic literature and grey literature. The selected databases for the search were Scopus, Web of Science, ProQuest, and Google Scholar, which provide extensive coverage of public administration, policy analysis, and evaluation studies. In addition to academic sources, relevant government reports and policy evaluations were retrieved from the DHS website and DPME repositories. These sources provide valuable firsthand insights into evaluating Outcome 8 programmes, which focus on human settlements and housing in South Africa. Manual searches were also performed using Google Scholar and government document portals to identify additional reports and studies that may have been missed during the initial search.

The SPIDER tool was employed to structure the search process. This framework was selected because it is particularly well-suited for qualitative and mixed-methods research [19]. Unlike the PICO tool, which is commonly used in clinical research to assess interventions and control groups, SPIDER is tailored for social sciences research, emphasizing the exploration of experiences, processes, and policy impacts [20]. This made the SPIDER tool ideal for this review, which sought to examine how evaluation findings are integrated into policy-making and decision processes within Outcome 8 programmes. The SPIDER components guided the search strategy, focusing on key components such as public sector programmes in Outcome 8, the use of evaluation findings, and institutional and

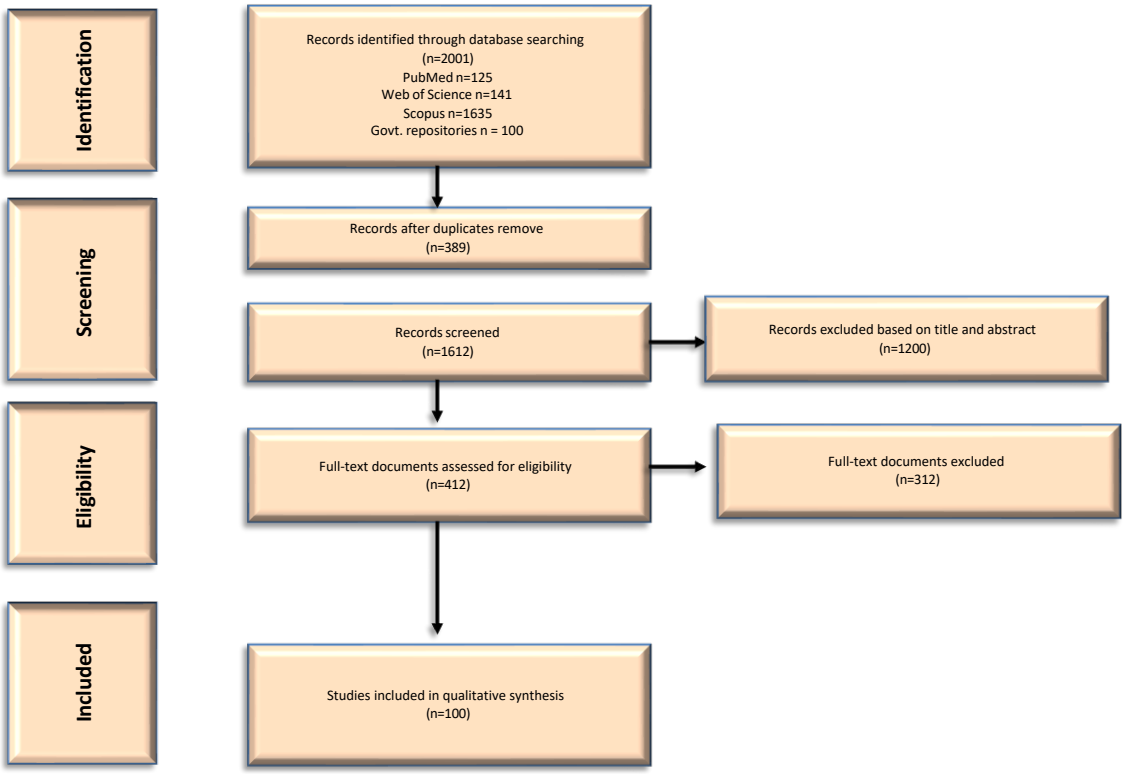
Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

political factors influencing evidence integration (see Table 2).

Table 2: SPIDER framework components for the search strategy

Component	Description
S [Sample]	Public sector programmes under Outcome 8, which focus on housing and human settlements in South Africa.
PI [Phenomenon of Interest]	The use of evaluation findings in South Africa's public sector and evidence-based policy-making (EBPM).
D [Design]	Qualitative research designs, such as case studies, document analysis, and thematic evaluations of government reports.
E [Evaluation]	Factors influencing the integration of evaluation findings into policy decisions, including institutional barriers, political considerations, and capacity constraints.
R [Research Type]	Qualitative and mixed-method studies focusing on evidence use, governance, and policy implementation.

The search utilized specific search terms and Boolean operators across the databases to ensure consistency and capture the most relevant studies. The search terms included combinations of Outcome 8, human settlements, South African housing policy, and phrases related to evaluation findings, evidence-based policy, and decision-making. This combination enabled the identification of studies focused on evaluation utilization, governance challenges, and evidence-based policymaking in South Africa's housing sector.



The search process unfolded in three stages: First, an initial broad search was conducted to capture a wide range of relevant sources. Then, title and abstract screening was performed to exclude irrelevant articles. Finally, full-text screening was conducted, applying thematic analysis to assess the relevance of each study to the research questions. Inclusion and exclusion criteria were strictly applied to ensure that only the most relevant and high-quality studies were included in the review.

2.3 Selection criteria

The selection criteria for this systematic review were designed to ensure that only the most relevant and high-quality studies were included in analyzing evidence use in Outcome 8 programmes in South Africa. The review examined how evaluation findings are integrated into public sector decision-making, particularly in housing and human settlements, which are central to Outcome 8 of South Africa's NDP. The focus was on identifying barriers and facilitators to evidence use in policy and programme implementation, particularly in addressing South Africa's socio-economic challenges. The search began with retrieving 2001 records from academic databases and government repositories. These records were sourced as follows: PubMed (n=125), Web of Science (n=141), Scopus (n=1635), and Government repositories (n=100). After removing 389 duplicates, 1612 unique records remained for title and abstract screening. At this stage, 1200 papers were excluded due to irrelevance based on their focus or title. The remaining 412 studies underwent full-text review, excluding 312 studies that lacked sufficient relevance to the research question. Ultimately, 100 papers were included in the final analysis. These comprised evaluations from the DHS, which provided insights into housing and settlement-related interventions, and peer-reviewed articles from academic journals, which contributed theoretical and empirical perspectives on evidence-informed policymaking in South Africa.

Figure 1: PRISMA Flow Diagram of Study Selection

The inclusion criteria for the studies selected were based on specific characteristics. First, only studies published between 2010 and 2024 were considered to align with the implementation of the NDP, which began in 2012. Studies had to focus on public sector programmes in South Africa, specifically Outcome 8 (housing and human settlements). They had to address evaluation findings used in policymaking or programme implementation within these sectors. Additionally, only qualitative and mixed-methods studies, such as case studies, thematic evaluations, and policy reviews, provided rich insights into evidence use in governance. Studies must also be published in English to maintain consistency and inclusivity. Studies that did not focus on public sector governance or were unrelated to South Africa were excluded. Furthermore, studies published before 2010 were excluded, as they did not align with the NDP's timeline. The inclusion criteria and their specifications are outlined in Table 4, which summarizes the key aspects that guided the study selection process.

Table 3: Inclusion Criteria for Study Selection

Criteria	Description
Publication Date	Studies published between 2010 and 2024, aligning with the introduction of the National Development Plan (NDP).
Study Focus	Studies that focus on public sector programmes in South Africa, particularly those related to Outcome 8 (housing and human settlements).
Study Type	Only qualitative and mixed-methods studies (e.g., case studies, thematic evaluations, policy reviews) were included.
Language	Studies published in English were considered to ensure consistency and inclusivity.
Exclusion Criteria	Studies not focused on public sector governance or unrelated to South Africa or Outcome 8 were excluded.

The 100 studies were thoroughly analyzed to identify the barriers and facilitators to using evaluation findings in Outcome 8 programmes. The studies were categorized according to their design and research focus to ensure a

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

comprehensive understanding of qualitative and mixed-methods perspectives on evidence-based decision-making in South Africa's public sector. Table 4 summarizes the distribution of the types of studies included in the review, providing an overview of the research focus and methodology of the selected studies.

Table 4: Distribution of Studies by Type

Type of Study	Number of Studies	Description
Government Evaluations	28	Reports from the Department of Planning, Monitoring, and Evaluation (DPME) and other government-led evaluations of Outcome 8, offering direct insights into policy implementation and impact.
Academic Journal Articles	30	Peer-reviewed articles focusing on the use of evidence in governance and public sector policy-making, particularly in housing and human settlements.
Case Studies	20	Studies examining specific Outcome 8 programmes or pilot projects, analyzing factors that facilitate or hinder evidence-based decision-making.
Policy Reports and Briefs	12	Reports from governmental and non-governmental bodies, including policy analysis on evidence-based governance and programme evaluations.
International Comparative Studies	10	Reports from organizations such as the World Bank and UN-Habitat comparing the use of evidence in public sector governance across various countries.

2.4 Quality assessment

The quality of the studies included in this systematic review was assessed independently by two reviewers using the Critical Appraisal Skills Programme (CASP) checklist. The CASP checklist is widely used to assess the methodological rigour of qualitative research. It provides a structured approach to evaluating the risk of bias and the appropriateness of the study design, data collection methods, and analysis procedures [21]. The checklist evaluates several key aspects of the study, including the clarity of the research question, the appropriateness of the methodology, and the transparency of the analysis.

For this review, the quality of each study was classified into three categories: strong, moderate, and weak. Studies classified as strong demonstrated a clear and relevant research question, appropriate research design, well-executed data collection methods, and a thorough and transparent analysis. These studies provided robust and reliable evidence relevant to the review's research questions. Studies rated as moderate exhibited some limitations in their design or analysis but still provided useful insights into the barriers and facilitators to evidence use in Outcome 8 programmes. These studies were included in the review, albeit with caution, given the limitations in their methodology. Studies rated as weak were excluded from the review due to concerns about methodological rigour, insufficient transparency, or potential bias in the study design or data analysis.

The quality appraisal process ensured that only studies with a high level of methodological rigour were included in the final analysis. This approach allowed for a more accurate synthesis of the factors affecting the effective use of evidence in public sector programmes under Outcome 8. Including both strong and moderate-quality studies ensured that the review was grounded in reliable evidence while acknowledging the limitations of some studies. The CASP checklist was chosen for this review because it is widely regarded as a reliable tool for evaluating qualitative studies, particularly in the context of public policy and governance [21]. By using this tool, the reviewers ensured that the studies included in the review met rigorous standards of methodological quality and that the findings were both relevant and trustworthy.

2.5 Data analysis and meta-synthesis

The study employed a meta-synthesis approach to systematically integrate qualitative findings from various evaluation reports, policy documents, and academic literature related to Outcome 8 of South Africa's National Development Plan (NDP). Meta-synthesis, unlike meta-analysis which statistically aggregates quantitative

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

findings, focuses on interpreting and conceptualising qualitative evidence to generate deeper contextual and theoretical insights [21; 22; 23; 24]. This method is particularly apt for social science and public policy research, where institutional complexity and human decision-making processes require nuanced synthesis [25; 26]. The choice of meta-synthesis was justified by the study's aim to uncover how evaluation findings are used—or neglected—in policy and programme implementation, particularly in contexts influenced by political, institutional, and organisational dynamics [27; 28]. Prior research also supports the use of meta-synthesis in policy studies for its ability to identify patterns across diverse evaluations and highlight recurring barriers and facilitators of evidence use [29; 30]. Through this approach, the study captures a comprehensive view of the structural and operational constraints affecting evidence uptake in Outcome 8 programmes.

The analytical process was guided by Grounded Theory (GT), which supports the development of new theories directly from systematically analyzed data [31; 32]. GT was well-suited to explain the institutional behaviours and social processes surrounding the use of evaluation findings in government policy [33; 34]. The analysis followed three stages: (1) open coding to categorize emerging themes such as institutional barriers, political interference, and capacity constraints [37; 38]; (2) axial coding to examine how these categories relate and interact—particularly how governance structures and political dynamics influence evidence use [39; 40]; and (3) selective coding to build a theoretical framework that explains how institutional processes and political incentives shape the (non)use of evidence in Outcome 8 [41; 42]. The use of MAXQDA 2020 software enhanced data management by supporting thematic mapping and relational coding [43], while constant comparative analysis ensured the refinement and validation of emerging themes [44; 45]. This rigorous analytical process resulted in a structured synthesis of the key factors influencing evidence integration in public sector programmes under Outcome 8.

Table 5: Codes Extracted in the Systematic Review and Meta-Synthesis of Studies

Main Classifications	Main Categories	Sub-Categories	Code
Institutional Barriers	**Institutional Capacity**	Lack of trained personnel, ineffective resource allocation	[9; 10]; [11; 12]; [13]; [14]; [15]; [16]; [17]; [18]; [11]; [9]; [13]; [19]; [20]; [16]; [13]
Governance and Organizational Barriers		Fragmented governance, poor coordination	[11; 12]; [19]; [9; 10]; [21]; [16]; [13]; [17]; [16]; [20]; [13]; [18]; [19]; [17]; [13]; [22]
Political Dynamics	**Political Interference**	Influence of political agendas on policy decisions	[20]; [13]; [18]; [19]; [17]; [14]; [13]; [20]; [9]; [19]; [11]; [14]; [10]
Shifting Priorities		Changes in government priorities affecting evidence uptake	[11; 18]; [9]; [14]; [16]; [19]; [13]; [16]; [10]; [12]; [13]; [18]; [11]
Data and Knowledge Management	**Data Availability**	Gaps in data across various levels of government	[10]; [13]; [16]; [11]; [20]; [19]; [18]; [13]; [9]; [18]; [19]; [14]; [17]; [13]; [13]
Data Consistency and Integration		Inconsistencies in data collection and integration	[9]; [11]; [16]; [13]; [14]; [19]; [18]; [16]; [19]; [17]; [13]; [17]; [11]; [16]; [13]; [18]
Capacity Constraints	**Technical Expertise**	Lack of skilled evaluators within government departments	[20]; [18]; [13]; [19]; [11]; [17]; [14]; [10]; [13]; [11]; [19]; [13]; [13]; [16]; [17]
Training and Development		Limited institutional training opportunities	[13]; [11]; [16]; [14]; [17]; [13]; [16]; [17]; [19]; [10]; [13]
Collaboration and Networks	**Evaluator-Policymaker Collaboration**	Weak interaction and feedback between evaluators and policymakers	[11]; [19]; [16]; [13]; [14]; [16]; [10]; [18]; [17]; [20]; [19]; [11]; [19]; [14]; [13]
Inter-Sectoral Collaboration		Lack of collaboration across	[9]; [11]; [19]; [13]; [16]; [12]; [13]; [22]; [19]; [18]; [13]; [16];

government sectors [21]

The findings from the meta-synthesis indicate that institutional barriers, political dynamics, and capacity constraints significantly affect the integration of evaluation findings into Outcome 8 programmes. These factors interact in complex ways, shaping how policymakers interpret and apply evidence in governance. The structured relationships between these elements are visualized in Figure 2, which presents the Grounded Theory Framework of evidence integration in Outcome 8.

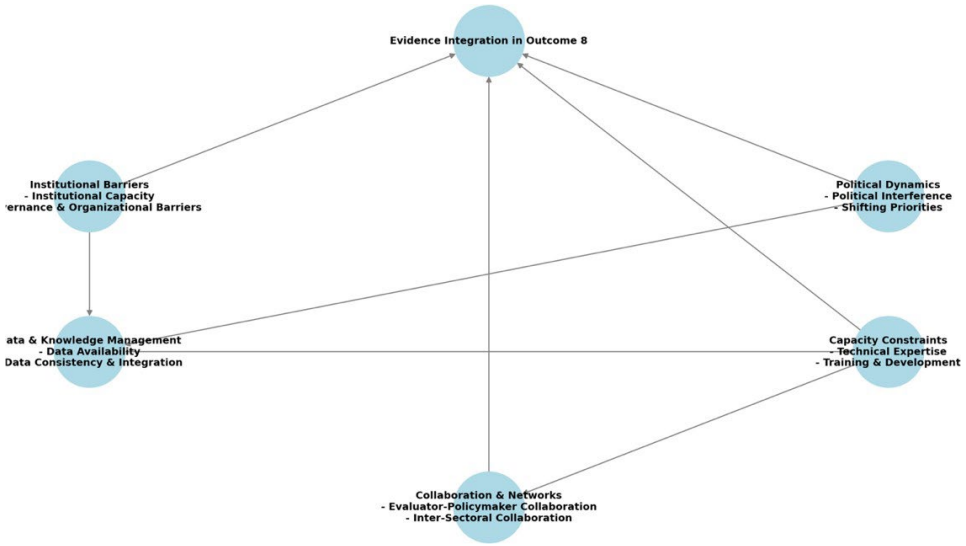

Figure 2: Grounded Theory Framework of Evidence Integration in Outcome 8 Programmes

The results of this meta-synthesis provide a theoretically grounded understanding of the processes governing evidence use in Outcome 8 programmes. The findings demonstrate that while institutional frameworks and political will are critical in facilitating evidence use, persistent challenges such as data inconsistencies, limited capacity, and weak collaboration between policymakers and evaluators continue to hinder effective implementation. These results contribute to a growing body of literature on evidence-based policymaking, reinforcing the need for strategic reforms that address governance inefficiencies and promote stronger institutional support for evidence integration in South Africa's public sector programmes.

3. Findings

2.1 Institutional barriers

A critical finding from reviewing Outcome 8 evaluation reports is that institutional weaknesses remain a persistent obstacle to integrating evidence into policy decisions. Across multiple evaluation cycles [9; 12; 14; 15], recurring issues such as inadequate institutional coordination, weak monitoring structures, and inconsistent implementation of evaluation recommendations were observed. Despite the existence of evaluation frameworks, most reports failed to demonstrate how findings were used to inform programme adjustments, highlighting a gap between evaluation production and its actual application in decision-making [9; 17]. This disconnect suggests that the institutional architecture for evidence use is either ineffective or inconsistently applied across different levels of government.

A further issue identified is that government departments responsible for implementing Outcome 8 programmes lack the necessary expertise to conduct and interpret evaluations effectively. Several evaluations noted that while data collection mechanisms exist, the analytical capacity to process and synthesize findings into actionable policies remains weak [10; 15]. Similar findings were reflected in broader research on evidence use in public sector decision-making, which has consistently pointed to the absence of evaluation literacy as a key barrier [11; 13]. The limited technical capacity of public officials to engage with evaluations reduces the likelihood that findings will be

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

utilized effectively, reinforcing the problem of evaluations being produced as compliance exercises rather than tools for policy learning [19; 20].

2.2 Political Dynamics

The review of evaluation reports revealed that political interference continues to be one of the most significant constraints to the effective use of evidence in Outcome 8 programmes. Across multiple evaluation cycles, there was a pattern of policy shifts and inconsistent implementation due to changes in political leadership [12; 14; 17]. The reports indicate that while evidence-based recommendations were formulated, many were either selectively applied or ignored due to political considerations rather than technical merit. This aligns with broader literature on governance challenges in South Africa, which highlights how short-term political pressures frequently override long-term, evidence-driven decision-making [18; 16; 13].

Another critical finding is that evaluation reports rarely address how political agendas influence evidence uptake. While some reports acknowledge that policy continuity is disrupted due to shifting government priorities [10; 15], they do not explicitly assess the role of political leadership in determining whether findings are implemented. This omission suggests a gap in framing evaluations—avoiding politically sensitive topics while focusing more on technical issues. Yet, the inability to critically engage with political factors results in evaluations that fail to explain why certain policies remain ineffective despite multiple assessments confirming their weaknesses [17; 14; 19].

2.3 Data Inconsistencies

One of the most striking patterns emerging from the evaluation reports is the persistent issue of data inconsistencies across national, provincial, and municipal levels. Multiple evaluations reviewed noted discrepancies in data collection, classification, and reporting standards, ultimately affecting policy assessment reliability [12; 15; 17; 19]. In particular, gaps in baseline data were repeatedly cited, making it difficult to measure progress or draw definitive conclusions on the effectiveness of Outcome 8 interventions [9; 17]. These findings are consistent with broader research showing that South African government departments struggle with integrating data across different levels of administration, leading to fragmented evaluation results [11; 13].

The inability to generate consistent and comparable data across evaluation cycles suggests a deeper structural issue with knowledge management in the public sector. While evaluation reports acknowledge this challenge, they rarely propose concrete solutions beyond recommending improved data management systems [12; 17]. However, external research points to deeper causes, such as the lack of standardization in how indicators are defined and measured across different evaluations [19; 16]. The evaluations fail to interrogate why these inconsistencies persist despite repeated recommendations, reinforcing concerns that evaluations serve more as retrospective exercises rather than forward-looking mechanisms for systemic reform [18; 13].

2.4 Capacity Constraints

A recurring theme across the evaluation reports was government departments' lack of capacity to effectively utilise evidence. Despite multiple recommendations for strengthening institutional capacity, the reports indicate that technical expertise in evaluation methods, data analysis, and evidence translation remains limited [9; 12; 17]. While some training initiatives were documented, their impact was not systematically assessed, making it unclear whether these efforts led to meaningful improvements in evidence use [10; 15].

Additionally, the lack of dedicated evaluation units within many government departments was identified as a critical weakness in the system [12; 15]. While policy frameworks such as the National Evaluation Policy Framework [9] provide guidelines for evidence use, these structures appear to lack the enforcement mechanisms needed to ensure compliance [11; 19]. The absence of institutionalized evaluation teams means that many recommendations are left to be implemented ad hoc, further limiting their effectiveness.

2.5 Collaboration and Networks

A key finding from the analysis of Outcome 8 evaluation reports is the weak interaction and feedback mechanisms between evaluators and policymakers, which significantly undermine the integration of evaluation findings into policy decisions. Despite the existence of formal evaluation frameworks, evaluators are often excluded from the policy development process, resulting in their recommendations being underutilized or ignored altogether [12;

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

17]. This lack of integration was evident in both DHS and DPME reports, which identified a critical feedback gap where evaluators were not consistently engaged during key policy formulation stages [9; 17]. The absence of structured platforms for sustained interaction between evaluators and policymakers further compounds the issue, weakening the impact of evidence on policy design [11; 19; 14]. While the importance of collaboration is widely recognized in literature on evidence-informed policymaking [20; 18; 19], the evaluations themselves rarely outlined practical mechanisms to foster such collaboration. The failure to institutionalize these engagements results in evaluations that have limited influence over the policymaking process, as highlighted by Cairney [20], Goldman et al. [18], and Strydom et al. [19], who note that irregular or informal engagement leads to inconsistent and fragmented evidence use [13; 14; 17].

Equally concerning is the lack of inter-sectoral collaboration across government departments involved in human settlements policy. Although human settlements inherently require coordinated efforts across housing, infrastructure, and service delivery sectors, departments frequently operate in silos, which undermines the integration of evaluation findings across policy areas [12; 17]. Evaluations by DHS and DPME show that misalignment between national, provincial, and local government departments hinders the systemic application of evidence, resulting in fragmented implementation and reduced policy effectiveness [9; 22]. This challenge is mirrored in broader governance literature, which emphasizes that weak interdepartmental coordination remains a core barrier to effective governance and evidence uptake [13; 19]. While DPME and Griessel et al. [17; 18] have proposed clearer governance frameworks and joint working structures, the review notes that these remain largely unimplemented. The continued failure to establish cross-departmental teams or institutionalized channels for collaboration reflects a missed opportunity to enhance the impact of evaluations. Without stronger inter-sectoral coordination, the potential of evidence to inform cohesive, multi-dimensional responses to South Africa's housing challenges under Outcome 8 remains unrealized [20; 11; 13; 16].

4. Discussions with Correct Reference Numbers

The findings of this study underscore that institutional barriers remain a significant obstacle to the effective use of evidence in Outcome 8 programmes under South Africa's National Development Plan (NDP). Evaluations consistently pointed out issues such as fragmented governance, weak institutional capacity, and inconsistent application of evaluation recommendations across government levels [62; 65; 69]. These institutional barriers hinder the integration of evaluation findings into policy decisions and prevent evidence from being translated into actionable changes. As [44] noted, the lack of skilled personnel to engage with complex evaluation data is a major contributor to this issue. The absence of trained evaluators and analysts within key government departments means that despite the availability of evaluation reports, their findings are not properly understood or utilized. Similarly, [64] and [62] have argued that inadequate institutional coordination between departments is another key factor limiting evidence-based policymaking's impact. To address these barriers, studies have emphasized the importance of institutionalizing evaluation processes through the creation of dedicated evaluation units, which would ensure consistent engagement with evaluation findings and foster better decision-making [33; 56]. Therefore, a critical enabler of evidence use would be strengthening institutional frameworks, ensuring the systematic use of evaluations, and providing departments with the necessary training and resources to engage with these findings effectively.

Political dynamics, particularly political interference, have been highlighted as another key constraint to effectively using evidence in Outcome 8 programmes. The review observed that political agendas often superseded evidence-based recommendations, with political actors prioritizing short-term gains over long-term, evidence-driven solutions [68; 60]. Shifts in political leadership or changes in governmental priorities often led to inconsistent implementation of policies, making it difficult for evaluation findings to shape policy decisions. These findings are consistent with the literature on evidence-informed policymaking, which shows that political factors, such as the lack of political will and political interference, frequently undermine the effectiveness of evidence use in policy-making [38; 57]. Establishing strong political will and leadership that prioritizes evidence-based policy over political considerations is an enabling factor in overcoming political barriers. For instance, studies have suggested that when policymakers commit to long-term strategies based on evidence, the integration of evaluation findings becomes much more feasible [101; 73]. Moreover, fostering a culture of evidence use among political leaders could significantly reduce the influence of partisan politics and lead to more consistent implementation of evaluation findings.

Data inconsistencies have been identified as a recurring challenge in the evaluation reports, undermining the

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

reliability of evidence used in policy-making [64; 49]. These inconsistencies—particularly the lack of standardized data collection processes across different government levels—pose a significant barrier to evidence-based decision-making. As found in the review, gaps in baseline data and discrepancies in reporting between local, provincial, and national levels made it difficult for policymakers to assess programme outcomes and make informed decisions [54; 11]. The lack of standardized data management and reporting systems is a significant issue that has been recognized in the broader literature on governance and evidence use [29; 76]. One key enabler to improving data use in policy decisions is establishing a centralized and standardized data management system that ensures consistency across all levels of government. Implementing data standardization protocols would allow for more reliable evidence to inform policy decisions, thus overcoming one of the primary barriers identified in this review. Moreover, creating an integrated national database for human settlement data would enable more effective tracking and monitoring of programme outcomes, facilitating more informed, evidence-driven decision-making [38; 55].

Capacity constraints, particularly the lack of skilled personnel and technical expertise, were another major barrier identified in the review. While some capacity-building efforts have been made, many government departments still struggle to employ the necessary skills for effective evaluation and data analysis [61; 17]. These findings are supported by global research, which indicates that insufficient evaluation capacity in government departments often leads to the underutilization of evaluation findings, as public officials lack the expertise to interpret and act on the results [10; 82]. Building evaluation skills through targeted training programs and establishing dedicated evaluation teams within government departments is critical to overcome these capacity constraints. Evaluators and policymakers must be provided with the tools and resources to engage with evaluation findings fully [81]. Furthermore, integrating capacity-building initiatives into government policy could enable officials to understand evaluation reports and apply them effectively in decision-making, ensuring that evaluation findings lead to substantive policy improvements [67; 59].

Collaboration between evaluators and policymakers was found to be weak, further limiting the effective use of evidence in Outcome 8 programmes [54; 69]. The review observed that evaluators were often not actively involved in the policy-making process, leading to a disconnect between the evidence produced and its application in decision-making. The importance of evaluator-policymaker collaboration in successfully integrating evidence into policy has been extensively documented [54; 53]. Creating more structured platforms for interaction and feedback between evaluators and policymakers could significantly enhance the impact of evaluations on policy decisions. As [60] suggested, establishing regular, formalized interactions between evaluators and policymakers would help ensure that evidence is continuously applied in the policy process. This could involve setting up joint task forces or committees that work together throughout the evaluation and decision-making process, ensuring that evidence-based recommendations are actively considered during policy formulation and implementation. Such collaboration would also foster a culture of evidence use within the public sector, ultimately leading to more effective governance and improved policy outcomes [62; 40].

Finally, the review identified weak inter-sectoral collaboration as another significant barrier to the effective use of evidence in Outcome 8 programmes. Despite the multi-disciplinary nature of human settlements policy, government departments often work in silos, leading to fragmented policy implementation and a lack of coordinated action [67; 56]. This issue of siloed working was particularly evident in the DHS and DPME evaluations, where failure to align efforts between national, provincial, and local governments hindered the effective application of evaluation findings [86; 79]. Establishing clear inter-sectoral governance frameworks and cross-departmental coordination mechanisms is crucial to overcome this barrier. According to research on governance in South Africa [60; 69], creating joint working groups or committees that span across various sectors would facilitate the integration of evaluation findings into comprehensive, multi-sectoral solutions. This would ensure that evidence is used more effectively to address complex human settlement and housing challenges, ultimately leading to better outcomes under Outcome 8. Strengthening inter-departmental collaboration would improve the quality of policy decisions and enhance government departments' ability to work together towards achieving shared goals.

5. Conclusion

Outcome 8 of South Africa's NDP, which focuses on transforming human settlements, remains a critical area for improving living conditions and addressing the housing backlog in the country. This study sought to explore the factors influencing the use of evidence in the design, implementation, and evaluation of Outcome 8 programmes. A

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

key finding of the study is the persistent challenge of integrating evaluation findings into the policy-making process. Despite a wealth of evaluations conducted over the years, the utilization of evidence in shaping policies for human settlement transformation has often been inconsistent, resulting in the recurrence of similar challenges across multiple assessment cycles. The study critically examined the recurring issues highlighted in evaluations of Outcome 8 programmes, identifying the factors that hinder the full utilization of evaluation results in policy and practice. These factors include weak institutional frameworks, inadequate government-level coordination, and a lack of capacity to interpret and apply evaluation findings. However, the study also pointed out several enablers, such as the establishment of strong institutional frameworks, enhanced inter-sectoral collaboration, and capacity-building initiatives that could significantly improve the use of evidence in shaping public policies. The study's findings underscore the need for more robust systems to ensure that evaluation evidence is produced and effectively used to guide decision-making, ultimately improving the effectiveness of Outcome 8 programmes. South Africa can strengthen its evidence-based policy-making approach by addressing these systemic barriers and fostering collaboration between evaluators and policymakers, ensuring that human settlement interventions are more effective and aligned with the country's development goals. This study contributes valuable insights into how evidence can be better integrated into public sector programmes, offering practical recommendations for improving the integration of evaluation findings into policy-making. The findings can potentially inform future strategies aimed at overcoming the challenges in implementing Outcome 8 programmes and enhancing their impact on human settlement transformation in South Africa. Ultimately, this study serves as a roadmap for improving evidence utilization in the public sector, contributing to better governance and more effective public policies.

Abstract. Digital transformation is increasingly reshaping the public and private sectors by enhancing the efficiency and quality of services. With the integration of emerging technologies such as Artificial Intelligence (AI), blockchain, and Internet of Things (IoT), this transformation is becoming a key driver in achieving the United Nations Sustainable Development Goals (SDGs). This shift has given birth to concept of the "triple transition" emphasizes the interconnected the social, green and digital transitions as part of a systemic approach to achieve the SDGs. However, for these technologies to generate meaningful public value, they must rely on high-quality, accessible, and interoperable data. Public Data Ecosystems (PDEs) , as networks of stakeholders engaging in data exchange across the data lifecycle, provide a foundation for transparency and accountability as elements of public value. Their capacity to create broader societal and economic value remains limited without the synergy of advanced digital technologies. To this end, this study proposes the concept of Triple Transition Ecosystems (TTEs) networks of actors leveraging both PDEs and the four-intelligence (4I) paradigm (Data, Artificial, Collective, and Embodied Intelligence) to generate multidimensional public value aligned with the SDGs. Using a systematic literature review that includes thematic analysis informed by public value frameworks, we examine the potential of TTEs across various policy domains. Our findings indicate that TTEs have the potential to generate public value in terms of better service quality and governance, but also higher societal value. By conceptualizing TTEs, this study offers a novel framework for understanding digital transformation as a systemic enabler of sustainable development and provides actionable insights for researchers and policymakers seeking to design triple transition–oriented policies.

Keywords. digital ecosystem; public data ecosystem; public sector; SDG; triple transition; triple transition ecosystem
Research paper, DOI: https://doi.org/10.59490/dgo.2025.1008

1. Introduction

Digital transformation refers tothe adoption and integration of new technologies by stakeholders across both public and private sectors (Gong & Ribiere, 2021). This transformation is widely recognized for improving operational efficiency (Wujarso, 2023), as well as enhancing quality of services in diverse institutional settings (Dias et al., 2022). Fueled by the momentum of the Fourth Industrial Revolution, emerging technologies are now playing an increasingly pivotal role in reshaping organizational processes and governance models. In this context, the so-called four intelligence paradigm (4I) was introduced by Verhulst (2021) constituted by (1) Data Intelligence (DI) - technologies that process and analyze large datasets (e.g., IoT, blockchain) to inform decisions, (2) Artificial Intelligence (AI) - algorithms, including machine learning and expert models, that automate processes and enhance decision-making, (3) Collective Intelligence (CI) that refers to citizen participation via co-creation, crowdsourcing, or digital assemblies, empowering diverse input and democratized governance and (4) Embodied Intelligence (EI) that stands for physical devices and systems that interact with their environment, such as robotics and sensors, driving real-world applications of digital insights.The adoption of 4I technologies not only enhances operational efficiency and service quality but also offers transformative potential for advancing broader societal goals. These technologies contribute directly to the achievement of the Sustainable Development Goals (SDGs) by enabling more sustainable, inclusive, and responsive governance and service delivery.. E.g., AI can enhance energy efficiency by analyzing historical consumption data and identifying optimal patterns, such as aligning energy use with renewable energy surpluses (Farzaneh et al., 2021), blockchain can ensure secure and transparent data

transactions, verifying the performance of public and private organizations in achieving SDG targets (Muheidat et al., 2022). Additionally, open data combined with citizen science initiatives amplifies diverse perspectives, fosters inclusivity, and supports informed decision-making to reduce inequalities and enhance societal outcomes (Moedas, 2018). The majority of the SDGs, such as those targeting climate action, poverty alleviation and gender equality are inherently linked to public value generation. This aligns closely with the emerging notion of the triple transition, the concept of the triple transition, which integrates digital, green, and social transformations into a unified framework for sustainable development. According to the OECD (2023), triple transition stands for "a systemic approach that places the interlinkages and interconnections of the environmental, digital, and social aspects of development at the core", while the EU (2023) refers to it as the social, green and digital transition, connecting it with the 17 SDGs. In this context, public value creation is multifaceted. Drawing on Meynhardt's (2009) framework, it can be understood across four dimensions, namely moral-ethical, hedonistic-aesthetical, political-societal and utilitarian-economic, each representing a critical aspect of how digital innovation can enhance collective well-being.

While all artifacts of the 4I paradigm have the potential of generating public value contributing to the achievement of the SDGs, their effectiveness is contingent upon the the availability of high-quality data. Accurate, complete, and reliable datasets are essential for trainingAI models that support informed decision-making, personalize user experience and improve service outcomes and customer satisfaction (Daneshjou et al., 2021; Deekshith, 2021).

In this context, Public Data Ecosystems (PDEs) emerge as foundational systems composed of data and diverse stakeholders ranging from public institutions and private sector to academia and citizens, interacting dynamically across the data lifecycle. PDEs facilitate the flexible exchange and management of data, enabling stakeholders to collaborate in data-driven decision-making. These ecosystems contribute to public value by promoting transparency and accountability through accessible information, such as fiscal records or environmental indicators, and by encouraging broad participation in data governance. While transparency and accountability align with moral-ethical and political-social values (Meynhardt, 2009), PDEs also have the potential to generate utilitarian and economic value – two types of values often disregarded by research. For instance, sustained growth in the data economy can drive innovation and long-term economic benefits, however, for such outcomes to be achieved, it is stipulated that PDEs are leveraged by emerging technologies (Farboodi & Veldkamp, 2022; Nikiforova et al., 2024), such as constituents of the 4I paradigm.

However, realizing this potential requires synergy between PDEs and 4I technologies. PDEs need technological enablers to unlock their full value, while 4I technologies rely on robust data ecosystems to function effectively.Addressing this interdependence by drawing upon the literature on PDEs, 4I and the triple transition (Pincheira et al., 2021; Farboodi & Veldkamp, 2022; Lnenicka et al., 2024; Nikiforova et al., 2024), we propose the concept of Triple Transition Ecosystem (TTE) that we define as a collaborative network of public and private actors, civil society, citizens and academia, in which stakeholders engage in data transactions and leverage 4I technologies to co-create public value and support the social, digital, and green transitions integral to achieving the SDGs. As TTE is built upon PDE, 4I, and triple transition, it is important to explore and conceptualize their convergence and potential for public value generation, which motivates this study.This study aims to conceptualize the TTE and explore its capacity to generate multidimensional public value by examining the convergence of PDEs and 4I artifacts. Specifically, we examine the roles of its key components - artifacts of the 4I paradigm and PDE. By investigating how these components contribute to public value creation, the study seeks to provide a deeper understanding of their interplay in fostering collaboration between public and private sector and civil society, driving innovation, and addressing societal challenges in the digital age. This research employs a systematic literature review (SLR), whose results are analyzed through thematic analysis, where to distinguish between types of public value being generated by TTE, a public value model inspired by the models of Meynhardt (2009) and Tweyzyimana & Andersson (2019) is used for code generation.

The results show that TTE has the potential to generate public value in a wide spectrum of policies, including land, tax, environmental, urban policy, as well as policies on cultural heritage, human rights, health and freight transport. Citizen participation, transparency, operational efficiency and sustainability are key elements of public value that can be generated by TTE. With this research we make a call for a discussion on the new concept of TTE and how public policy can promote their development in a manner that can spur the generation of public value.

The rest of the paper is organized as follows. In the second section, we provide a background on PDEs and the 4I paradigm, their potential to generate public value and their limitations and introduce the concept of TTE. The third section presents the methodology. In the fourth section, we present the results of the analysis with the fifth section constituting a discussion of the findings. The final section concludes the study.

2. Background

The process of digital transformation has become increasingly significant globally during the past decade, as both public and private services rely heavily on digital practices and processes (Alvarenga et al., 2020; Brunetti et al.,

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

2020; Dener et al., 2021).

A parallel shift observed over the past decade is the global commitment of the United Nations (UN) members to the SDG agenda (Biermann et al., 2019). Countries worldwide are setting ambitious targets to address critical challenges, such as mitigating climate change, eradicating poverty and inequality, and fostering sustainable economic growth.

Digital technologies play a pivotal role in advancing SDGs (Mandejar et al., 2021), Jones et al., 2017). For instance, AI models can be trained on historical energy consumption data to identify consumption patterns that maximize energy efficiency. Examples include using energy when there is renewable energy surplus, recommending using appliances in the most efficient manner or finding the optimal time to use Vehicle to Grid (V2G) or Vehicle to Home (V2H) technologies (Farzaneh et al., 2021). Blockchain, in the form of a complex hashing algorithm, can be used for key and signature matching to verify data transactions, which can be helpful to avoid fraud during data exchanges that might be relevant to show the performance of public and private sector organizations with regards to achieving the aforementioned SDGs (Muheidat et al., 2022). Open data can also have an impact on SDGs. When effectively coupled with citizen science initiatives (as part of CI), it has the potential to amplify diverse perspectives and contribute to reducing inequalities by increasing transparency, inclusivity, and informed decision-making (Moedas, 2018), although yet to be improved.

Moreover, to monitor and evaluate the performance of public and private sector organizations against SDGs, coordinated data collection and analysis strategy, combined with robust digital governance frameworks (incl. data governance frameworks) are paramount. While data collection strategies focus on ensuring high-quality data collection in a cost-effective manner, while addressing concerns related to data privacy and anonymity concerns (Johnson & Turner, 2003), data governance frameworks encompass the entire data lifecycle—collection, storage, processing, and disposal (Abraham et al., 2019). This data collection is expected to be conducted in a manner that ensures the representativeness of samples from all affected groups, while also guaranteeing the quality and accessibility of data. Emerging technologies, such as IoT, drones, AI-driven tools and intelligent devices can enhance data collection from diverse sources (Plageras et al., 2018), thereby increasing representativeness of data and informing decision-making (Asghari et al., 2019; Plageras et al., 2018). Additionally, CI can significantly contribute to the data collection process. Initiatives such as living labs and crowdsourcing are effective in gathering data and public opinions on societal and environmental topics. These approaches not only enhance data diversity but also have the potential to democratize political decision-making (Hossain & Kauranen, 2015)—provided there are effective communication channels between citizens (that will participate in these collective initiatives) and decision-makers, and these channels are used actively and effectively (Hossain & Kauranen, 2015; Lnenicka et al., 2024).

PDEs, facilitating dynamic data exchange among diverse stakeholders (e.g., government, private sector, citizens, academia), possess the potential to significantly enhance data availability and contribute to the achievement of the SDGs by generating substantial public value.

PDEs can enhance transparency and accountability by increasing data accessibility for all stakeholders. Citizens, for instance, can readily access publicly generated data, such as fiscal, demographic, and socio-environmental indicators (e.g., unemployment, poverty, equality, environmental pollution), empowering them to engage more effectively in SDG-related initiatives. Moreover, increased transparency in data transactions fosters accountability by clearly delineating the contributions of each stakeholder within the ecosystem, ensuring data quality and completeness from all participating entities.

However, the concept of public value extends beyond trust and institutional legitimacy associated with accountability and transparency. Following Meynhardt (2009), public value encompasses the multifaceted relationships between individuals and the broader "society," encompassing all entities with which an individual interacts, including both public and private sector actors. Meynhardt (2009) categorizes these relationships as: (1) moral-ethical, (2) hedonistic-aesthetical, (3) political-social, and (4) utilitarian-instrumental. While accountability and transparency primarily align with moral-ethical and political-social values, a notable gap exists in the current discourse regarding the contribution of PDEs to other facets of public value, particularly the utilitarian-instrumental domain. This gap is exemplified by the limited exploration of strategies for operationalizing the data economy (Hilbert, 2016).

Regarding the utilitarian and economic value of data, it has been argued that a thriving data economy necessitates the conceptualization of data as a long-lived, depreciating, and tradable asset. To sustain long-term data value -and possibly it growth- it is imperative to integrate data into research and development activities, enabling continuous innovation and the accumulation of new knowledge (Farboodi & Veldkamp, 2022). Consequently, the effective utilization of data through emerging technologies to foster novel innovations can significantly enhance the societal value of PDEs. To this end, a new so-called four intelligence paradigm (4I) encompassing AI, DI, CI and EI (Verhulst, 2021)) seems reasonable to be addressed and integrated into the current landscape.

According to 4I (Verhulst, 2021), DI encompasses technologies and methodologies that enable the analysis and

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

processing of large datasets generated from diverse sources, including devices, sensors, and operations within both public and private sectors. The processing and analysis of such data within the DI framework hold significant potential for enhancing decision-making processes. Three key components constitute DI:

1. **open data** that refers to data systems, where all stakeholders within a data ecosystem have consistent access to datasets, enabling them to analyze, utilize, and redistribute databased on their specific interests and motivations;

2. **data collaboratives** resembling living labs and citizen science projects that are typically led by private sector entities in collaboration with civil society, through which data is exchanged to generate public value;

3. **IoT** that facilitate the real-time extraction and availability of data generated by devices, with common applications including household electronic appliances and sensors strategically placed within infrastructure grids, such as water or energy systems;

4. **Distributed Ledger Technologies (DLT)/blockchain** technologies that contribute to DI by employing advanced cryptographic techniques to ensure data storage and distribution in a transparent manner, while addressing privacy concerns through mechanisms like “smart contracts.”

Artificial Intelligence

AI within 4I is defined as computational processes designed to perform tasks traditionally carried out by humans (Verhulst, 2021). AI has evolved to include models capable of informing decision-making processes. Two primary artifacts of AI relevant to the intelligence paradigm are:

1. **Machine Learning (ML)** that leverage data to "learn" and generate actionable insights, thus informing decision-making processes;

2. **expert models** specifically designed to replicate human cognitive processes, with their application restricted to decision-making tasks.

Collective Intelligence (CI)

CI, in turn, shares similarities with data collaboratives but focuses on engaging individuals, irrespective of their stakeholder group, to foster citizen participation (Verhulst et al., 2021). CI manifests in several forms, with individuals contributing via smart devices or participating in physical events, such as citizen assemblies, with key artifacts of:

1. **participatory co-creation** involving the use of technological tools to gather data from stakeholders across an ecosystem, which is particularly relevant to geospatial data, where mapping tools integrate individual contributions with spatial datasets;

2. **(smart) crowdsourcing** that, while similar to participatory co-creation, focuses on collecting qualitative data, such as community improvement ideas or problem identification, from stakeholders;

3. **(digital) citizen assemblies** that combine networking opportunities with digital tools in physical settings to enable citizens to co-create policies. Unlike crowdsourcing, citizen assemblies operate with a defined agenda centered on local policies, leading to the designation of these initiatives as "crowdlaw."

Embodied Intelligence (EI)

Finally, EI encompasses AI components that are used in the physical world (Verhulst et al., 2021). The main purposes include automation of industrial processes such as manufacturing, as well as providing real-world, and real-time information on matters such as air quality and health, with EI artifacts entailing:

1. **robots as** reprogrammable machines that can harness the power of AI software to perform automated tasks that have mostly been deployed in the manufacturing sector, with other applications being at a nascent stage;

2. **drones** (also known as unmanned aerial vehicles (UAVs)) - aerial vehicles that are either controlled by remote pilots or by AI software.

According to Verhulst et al. (2021), the interconnected paradigms of DI, AI, CI and EI with its unique artifacts and methodologies collectively enhance data-driven decision-making and citizen engagement. According to this intelligence paradigm, emerging technologies generate novel forms of intelligence that, either independently or in

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

combination, can enhance governance and drive innovation, contributing to addressing multiple SDGs.
However, the different types of intelligence have a similar gap ought to be addressed. They rely on high-quality, reusable data, which remains a critical gap. E.g., AI does not yield the expected results in sectors like healthcare because of the lack of adequate data availability with, radiology and nuclear medicine research and development entities requiring data to train AI models that can help more easily detect suspicious diseases based on X-ray scans (Kocak et al., 2019). However, there are no (public/open) data ecosystems yet developed that can help increase data availability, rendering the utility and potential for public value of AI in this sector rather limited. Similarly, DI artifacts require synergies with PDEs to increase their potential for public value generation. As an example, open data or data sharing initiatives in the horticulture industry can bring benefits to local farmers, who will have larger data availability that will help them make better investment decisions on their infrastructure (Cazacu et al., 2023). Data sharing can also help them make other types of decisions, such as switching crops (De Prieelle et al., 2020). Such examples are evidence for the need for data availability covering the different artifacts of the 4I paradigm that would facilitate generation of expected public value.

This, however, creates a certain controversy. On one hand, PDEs require synergies with artifacts of the 4I paradigm to generate forms of public value beyond transparency, accountability and openness. On the other hand, these technologies require data availability to have meaningful impact for the stakeholders that utilize them. To tackle this controversy, we introduce the concept of TTEs. We define a TTE as *an extensive network of actors, including public, private sector, civil society and citizens, which are actively involved in data transactions and by leveraging artifacts of the four intelligence paradigm facilitates maximization of public value, based on their own personal interests, primarily, but also for the public good*. This definition is informed by academic discourse about PDE and its subsets (such as ODE) and how they can operationalize the data economy (Lnenicka et al., 2024), as well as practical challenges associated with data availability for unlocking the application of artifacts of the 4I paradigm, such as AI (Daneshjou et al., 2021) and blockchain.

Whilst there has been research on the utilization of emerging technologies to generate different elements of public value (Madan & Ashok, 2023), such as increase efficiency of services or make operations more sustainable (Nishant et al., 2020), as well as the potential of PDEs to generate public value through transparency, openness and accountability (Reggi & Dawes, 2016; Lnenicka et al., 2022), there is lack of clarity on the holistic public value that their synergy -or what we refer to as TTEs- can create. Even though evidence from literature demonstrates that artifacts of the 4I paradigm require data availability to increase their impact, but also that PDEs alone have limited public value, there is a lack in studies examining the relationship between artifacts of the 4I paradigm and PDEs in the context of creating public value, which is the gap we address.

As such, the main objective of this study is to conceptualize a TTE comprising artifacts of the 4I paradigm and PDE, and explore its potential for supporting data-driven and evidence-based policymaking that results in public value generation. This will inform the exploration of the types of public value that TTE can create, in terms of societal, ethical, utilitarian and aesthetic value (Meynhard, 2006).

3. Methodology

To attain the set objective, a systematic literature review (SLR), followed by a thematic analysis to generate codes based on the potential of TTEs to generate public value is conducted. Code generation was informed by a meta-synthesis of the e-government public value framework introduced by Tweziyimana & Andersson (2019) and the public value framework by Meynhard (2006). Our SLR followed guidelines proposed by Kitchenham (2004), namely identification of research objectives, selection of primary studies, study quality assessment, data extraction and monitoring and data synthesis. The first step includes familiarization with the existing research, through preliminary research. As a second step, we identified keywords for the query, namely on the convergence between PDEs and artifacts of the four intelligence paradigm.The search query was defined as a combination of "public" and "data ecosystem" terms, where the latter was accompanied with alternative resulting in*("data ecosystem" OR "data infrastructure" OR "data space" OR "data system" OR "data collection ecosystem" OR "dataset* ecosystem" OR "data set* ecosystem" OR "data on the web ecosystem") AND ("public"),* which was used to query Scopus, WoS and Google Scholar.

The selection of the keywords with regards to PDE is justified by the multiple structures of data ecosystems that have been described or introduced by scholars (Lnenicka et al., 2024), which includes data infrastructure (Maretti et al., 2021), data ecosystem (Schade et al., 2015), data system (Formosa, 2014), as well as data space (McKenna, 2017). To make the connection to the 4I paradigm, the protocol was developed to document analysis of researched studies that examined the convergence of PDE with at least one of the 4I paradigm artifacts.

During the identification process, a total of 1,121 research papers were identified. After the screening process, 573 papers were excluded as sector-specific. Only studies pertaining to the fields of computer science, information technology, public administration, and engineering were retained as most relevant to TTEs, which are inherently linked to computer science, information technology, and engineering, with a public value component aligned with

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

public administration and management. Only studies published in the period between 2014 and 2024 were retained to render the most relevant to this study, with older studies seen as less pertinent to TTE due to the rapid pace of technological advancements. Furthermore, the inclusion criteria encompassed conference proceedings, book reviews, and publications in scientific journals.
Subsequently, an eligibility analysis was conducted. During this stage, all studies in language other than English were excluded, reducing the pool to 370 studies. An eligibility check involved the manual exclusion of studies deemed irrelevant to the research topic based on title and abstract, as well as studies with only titles and abstract in English. As a result, only 152 research papers were selected for analysis (see Figure 1).

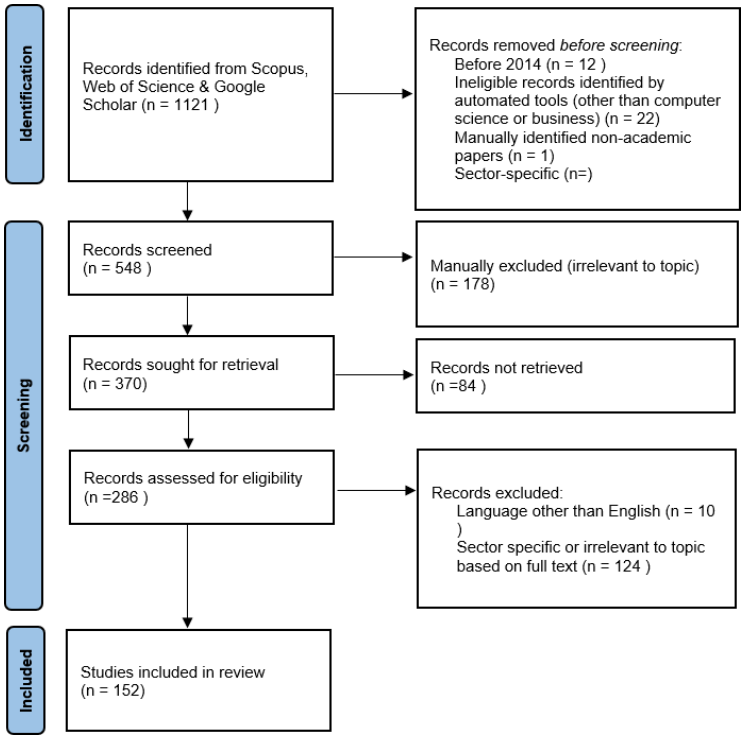

Fig. 1. Systematic Literature Review Process

The analysis of these studies was documented in a protocol developed by Lnenicka et al. (2024) to assess literature on PDEs. Following that, the final selection of studies was assessed based on this protocol that was developed as part of this research. The protocol consists of a series of questions that are presented in Table 1.

Tab. 1: Part of the protocol used in the SLR. The protocol will be disclosed in full in Zenodo upon paper acceptance.

Question Sector	Question
PDE-Specific	PDE/ODE Involved?
	Other terms related to ODE/PDE or other types of data ecosystems?
	If openness is not explicitly mentioned, does the study incorporate public and/or private components?
	- If yes, what is the structure of the ecosystem proposed?
	What stakeholders are involved in the ecosystem proposed?
	Which stakeholders are highlighted as most important?
	What types of data are involved in the ecosystem proposed?
4I-Specific	Is DI covered?
	Is AI covered?
	Is CI covered?
	Is EI covered?
	What are the artifacts it consists of/contains?
	Who are the stakeholders associated with the research on these types of intelligence and what roles do they fulfill?
	How is each type of intelligence affecting/what is its role in PDE/ODE?
	Is there any convergence of multiple intelligence paradigms?
	If so, what types of intelligence and what artifacts are involved?
	What artifacts are being integrated and through which methods/processes?

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

The next step included thematic analysis, which was conducted according to the six-step approach by Braun and Clarke (2006) extended by Maguire and Delahunt (2017). This approach suggests starting with familiarization with data, which is initiated after the SLR, followed by generation of the first set of codes that are then converted into themes. These themes are then reviewed and assigned final names and definitions, which we present in Results section.

Several public value frameworks informed development of the codes and themes. For example, the widely used public value scorecard proposed by Moore (2012) is used to assess the application of existing technological artifacts and systems and is not applicable for conceptual models, with the model by O'Flynn (2007) facing the same issues and targeting solely public managers. This comes in contrast with the theme of this study, which aims at conceptualizing the introduced term, encompassing stakeholders including private sector and citizens. Taking this into account, a meta-synthesis of frameworks took place. The initial framework that was used as a reference model for our integrated model is the model developed by Meynhardt (2006). Even though it is only conceptual framework, this framework can also be used for operational purposes and converted into a scorecard. As the framework is not directly related to assessing the public value of technology, the dimensions of public value are not broken down into the four categories provided by the author in his follow-up work (Meynhardt, 2009). Instead, the e-government public value framework, developed by Twizeyimana & Andersson (2019) is being adapted. According to this model, the dimensions of public value for e-government are improved public services, improved administration and improved societal value. The main categories of the e-government public value model are relevant for all digital technologies and all sectors (public and private), however the sub-categories are only relevant to the e-government sector. Hence, these categories are being reshaped and merged with the Meynhardt (2009) model into a framework as presented in Figure 2. All pillars from the model by Meynhardt (2009) were integrated into the category of the model by Twizeyimana & Andersson (2019) considering their individual suitability. For example, transparency and accountability fit most governance, whilst reliability and efficiency of services - improved service quality.

Fig. 2: Public Value Framework for TTE SLR

Based on this framework, the themes and codes that have been identified above as elements of public value are used to understand the type of public value that each instance of the TTE (PDE, four intelligence paradigm) can create. In addition, as part of the conducted SLR, we seek for identifying sectors/types of policy where the (potential) value of what we call TTE was studied.

4. Results

The results of our SLR show the convergence of PDEs and artifacts of the 4I paradigm as identified in literature can act as catalysts to generate public value in various policies. This convergence was found to have the potential to inform land, tax, environmental, urban, health, human rights, cultural heritage and freight transport policy, which we elaborate on in more detail below.

Land policy

TTEs in land registries hold promise to enhance operational efficiency in the public sector, even if the first attempts were not met with success. This is evidenced by Denmark in 2009, which was successful in reducing the time intensity of land registry procedures, but also faced deficiencies, such as the lack of mechanisms to verify land-

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

related data, such as geographic data (Naghavi et al., 2022), which is suggested to be tackled by blockchain systems that harness PDEs. More specifically, Voluntary Geographic Information (VGI) systems constitute a new way of crowdsourcing of geospatial data (**CI** artifact), increasing **citizen involvement** (Naghavi et al., 2022). Combined with blockchain to verify and secure data transactions (**DI** artifact), they can be used by land registries and then visualized to improve **efficiency** and simplify the service itself (Kliment et al., 2016). This can be in a form of a private/restricted blockchain based on majority consensus, where the users can use hashing algorithms such as SHA256 or Proof-of-Work (PoW) algorithms to ensure the validity of geospatial data entered that are related to a piece of land, so that the land registry can update all the characteristics of different assets (Krishnapriya & Greeshna, 2020).

Tax policy/Compliance

The aforementioned use of blockchain (**DI**) and VGI (**CI**) systems extends to tax policy. Firstly, this combination can serve as a proof for the tax obligations that stem from land property. Secondly, other artifacts combinations with blockchain can support provision of tax obligations for other assets. As an example, images of assets (such as land property, houses) generated through citizens' devices can then be processed by **AI** for their categorization to understand the type of asset and their value (Petersen et al., 2019). The "cleaned" data can then be validated by blockchain, which can be converted into proof of assets for citizens, which can then be taxed accordingly, further improving **operational efficiency** for the departments of finance at local, regional and national governance level. Similarly, this can be used for whistleblowing cases, where illegal buildings or other assets are not registered and, through this digitized process and using citizen-generated data from PDEs changes in taxation or recompenses can be administered financially for **citizen participation** and **transparency** purposes. Finally, TTEs can increase efficiency, when Generative **AI** harnesses publicly available financial reports of firms and checks them against existing tax policies and regulatory frameworks (Chen et al., 2024).

Urban Planning

The transformative effect of TTE is also foreseen in urban planning. An example includes the proposition of PFLOW (Kashiyama et al., 2017), which proposes an open data system, where data inputs by citizens can be provided voluntarily about their movements, either within their vehicles, public transportation or on foot, to understand traffic patterns (**CI**). Such a system, complemented by a GIS system, has the potential to support urban planning through **citizen participation**. As the voluntary data generated and provided might require cleaning or verification, **AI** and blockchain (**DI**) can find their use in this context and, following that phase, the final datasets can be harnessed by urban planners to help making cities more livable, reducing traffic and improving **sustainability**.

Environmental policy

There is some evidence that environmental policy is a potential beneficiary of TTE. Environmental monitoring is one of the cases where TTEs can have added value. Open government data portals can enhance **transparency** of governments, increasing the availability of environmental data, such as CO2 emissions (Misra et al., 2017). However, this data should be provided in a clear format being easy to understand by diverse stakeholders, with every stakeholder having a suitable data literacy level (Hintz et al., 2023). For that to occur, **AI**'s data curation, cleaning, alignment, sketching and processing potential can make data clearer, understandable and reusable (Purawat et al., 2021), whilst data collaboratives (**CI**) can, in the long term, improve environmental data literacy among citizens (Verhulst et al., 2023). According to Shusha et al. (2023), developing an open data ecosystem (**DI**), where space data are deposited increasing **citizen participation**, has been largely beneficial for actors such as the Swedish Forestry Agency and other governmental entities that work on the environment in Sweden. While this research focuses on open data ecosystems, the concept can be expanded to a broader concept of PDEs OGD is a subset of, having the benefit of larger data availability due to the participation of more stakeholders in the ecosystem. Providing clean space data can support these agencies, as they can introduce them into their AI models (**AI** artifacts) and generate insights of expected environmental degradation under different environmental policy scenarios, thereby supporting **sustainability**. Other cases include smart cities, where sensors and IoT technologies (**DI**) are deployed within a city context referred to as "urban tech" and allow cars, buses, bicycles, and citizens to collect data about air quality, noise pollution, and the urban environment at large, through sensors installed in the vehicles, as well as devices operated by citizens (Zerza & Park, 2020). These types of data can be then leveraged by municipalities to understand the level of environmental degradation in real time, shaping policy accordingly and reducing the response time.

Another case where TTEs can be useful for environmental policy is energy and resource efficiency. Resource efficiency and overall environmental conservation requires even larger amounts of diverse data. E.g., while datasets with overall or even per region energy consumption can help inform policy making at a macro level, combination with geodata provides information on the energy consumption for individual buildings, which can result in a spatial visualization of energy consumption patterns and, thus, make interventions in

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

buildings/neighborhoods where, for example, high energy usage is being observed. Other examples include using geodata to estimate the solar rooftop potential of each neighborhood and install photovoltaic panels where this potential is the highest (Mainzer et al., 2017). This, in turn, can take place using satellite imagery and drones (**EI**). Moreover, due to the large amounts of data processed by **AI**, there is the issue of sustainability that ought to be addressed, with green computing being one of emerging solutions to the sustainability conundrum, which includes e-waste minimization, as well as innovations such as energy efficient hardware, virtualization software and green algorithms, that result in the minimized use of energy during their runtime (Lannelongue et al., 2021).

Health Policy

Health policy can also largely benefit from a TTE. Ahmad et al. (2022) provide an overview of how healthcare can be transformed from this convergence in a smart city context. There are four models that can be used for digital transformation of healthcare. In healthcare 1.0, stakeholder participation in PDEs is very low, with no 4I artifacts and no public value associated with this model. In healthcare 2.0, there is slightly higher participation of stakeholders in PDEs, however, 4I artifacts are still not used and the only public value-related benefit is an increased efficiency. In healthcare 3.0, there is a high level of **citizen involvement** in PDEs, with EI artifacts such as wearables and artificially intelligent devices, resulting in **citizen participation** and **reliability** of results. Finally, in healthcare 4.0, there is a very high involvement of stakeholders and, in addition to **EI**, **DI** artifacts such as blockchain can be observed, as well as **CI** artifacts, such as citizen science (termed as big medical data) to ensure privacy, in addition to the foregoing public values.

Human Rights

A convergence of PDEs and artifacts of the four intelligence paradigm can be of use also for the human rights policy, in two manners. First, in relation to digital rights. Calzada & Almirall (2020) propose the development of GovTech labs in cities, using global examples and applying them to the case of Barcelona. These ecosystems employ public AI and public analytics, powered by blockchain (**DI**) to ensure anonymization processes and privacy-preserving procedures during co-creation in citizen science structures (**CI**), which include data commons. This is a dynamic type of infrastructure, whereby citizens actively provide their inputs in the data commons, which then are used to inform legislation around digital rights, leading to increased **citizen participation**. Human rights policy in general can be informed in a similar way. Nelson & Zanti (2020) propose a framework, where PDEs are complemented by data collaboratives (**CI**) and the use of machine learning tools (**AI**) to understand whether racial equality principles are respected in certain areas within a country. This is largely useful to inform policies relevant to minorities and indigenous communities in countries that have these populations, indirectly related to **human dignity**.

Cultural Heritage

In addition, policy around cultural heritage can be affected. E.g., Vahidnia (2023) explored how open data ecosystems can help inform urban decay through the support of VGI (**CI**), proposing a framework, where municipalities, civil society organizations and the private sector working on tourism develop a spatial data infrastructure (SDI), combined with a collection of other data, such as images, being crowdsourced by stakeholders and then introduced into a living lab (**CI**). These data are then processed within living labs and, following a co-creation process, policy recommendations are used to help preserve buildings of importance for **cultural heritage**.

Freight and Long-Distance Transport Policy

Lastly, the possibility of informing long-distance transport policy emerged as a pattern, with freight logistics in focus, in particular. Horizontal collaboration among stakeholders through smart contracts, using blockchain (**DI**), that harness open data and using **AI** to develop emission scenarios for different policies based on the aforementioned data is considered an efficient measure to track CO2 emissions in freight transportation from the governance side (Larsson et al, 2024). Environmental monitoring is deemed as the main reason for the utilization of this convergence in this case, resulting in enhanced **sustainability**.

Thus, TTEs have a role to play in several different policies as summarized in Figure 3.

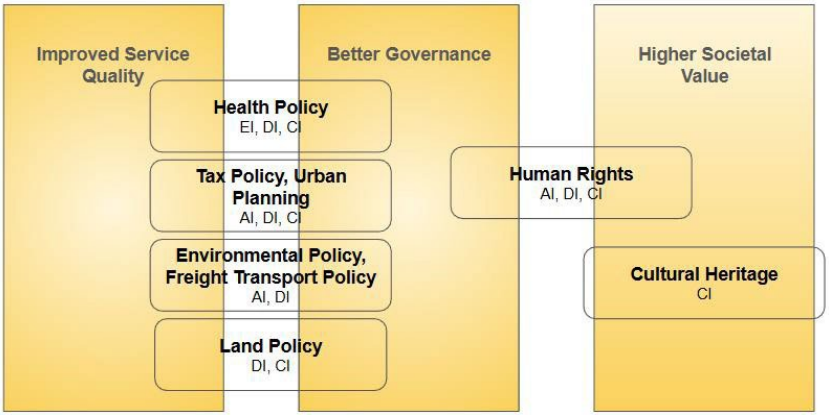

Fig. 3: Impact on TTEs in generating public value in policies

5. Discussion

The results show that TTEs hold promise to generate public value in various sectors and through several different means. Its approach can have benefits for policies in several sectors of the government. It can improve sustainability through energy efficiency in the built environment, which is a public value important in the smart cities sector. Local governments are increasingly implementing smart city initiatives and, according to the definition by the European Commission (n.d), upgrading energy and water infrastructure, as well as the built environment to become more efficient and sustainable is one of the key aspects of a smart city. Hence, TTEs have the potential to generate public value in the form of sustainability for the smart city realm.

Another sector where TTEs are a promising solution to generate public value is cultural heritage. This requires collaboration between macro and micro levels, namely national and local governments. The use of VGI and combination with AI can contribute to comprehending the level of decay that different cultural and historical heritage sites have undergone. Citizens' role can be instrumental in this application and, if organized as a crowdsourcing initiative, it can be an example of CI application for cultural heritage purposes. However, the majority of cultural heritage preservation projects involve the financial and operational capacity of the relevant responsible bodies such as ministries. The public value that can be created, apart from preservation of cultural heritage, is also aesthetic, since cultural heritage sites are usually considered to be visually and aesthetically appealing.

The potential to generate public value at both a micro and a macro level is also significant in tax and land policy. VGI has been portrayed as a means to increase data availability on land and other assets that individuals possess. This informs both local and national governments with regards to the assets of each individual for two purposes - first, to develop social policies such as social housing and the second - to tax individuals, so that less cases of tax evasion occur. Correspondingly, this implicates data that are collected at a local level, usually applying citizen science methodology. Data collected through citizen science are then transferred to the Ministry of Finance. The public values associated with the use of TTEs in this policy are efficiency, as well as accountability.

The last policy that is applicable to coordination between micro and macro level of governance as identified by this study encompasses human rights. CI and open data, in the form of citizen science initiatives such as data commons, can be used both to understand how citizens perceive the adoption of technology from the public sector and to what extent it ensures their personal dignity, but also how emerging technologies such as AI and machine learning are addressing (or not) diversity, equity and justice aspects of our society. Hence, TTEs have the potential to also generate public value related to humanitarian/societal causes.

Finally, there is a policy that covers only the macro level. This is the freight and long-distance transport policy. Tracking emissions using open data on the emissions of the different transport routes and exchanging data between governmental agencies through blockchain can help increase transparency and understand the bigger picture with regards to the contribution of long-distance and freight transport in the overall environmental pollution. This is related also to sustainability.

6. Limitations

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

This study has several limitations. The first is related to the choice of public value frameworks used in this study to explore the potential of TTE for public value generation. Several frameworks exist, having elements going beyond those covered by used framework, some of which could be useful to assess public value generation potential of TTEs, e.g., recreational or historical values as comes from (Zhang et al., 2024). These values, however, seem to have a low probability of being generated by TTEs and, thus, were not taken into account in this study.

Another limitation lies in the applicability of the results. The majority of the cases found in literature, where a convergence of PDEs and 4I artifacts has the potential to generate public value, are conceptual. Hence, it is recommended that different case studies are developed. Case studies should include interviews with relevant stakeholders to explore how the concept of triple transition ecosystems could be operationalized, what its actual potential to generate public value is, and what the main obstacles are.

Finally, there are public values that are not distinguished in literature, such as accountability and transparency. Accountability focuses on the ownership and responsible behavior and, in the context of open data, is related to ensuring that data privacy regulations are being taken into consideration. In some cases, this is rather challenging, as datasets possess sensitive data, such as personal information of citizens, but also data that is important for reusability services, such as health-related epidemiological data that are crucial to inform decision-making. To this end, blockchain technologies can be used in combination with PDEs to ensure anonymity and respect towards data privacy, however, so far literature has not addressed accountability alone.

7. Conclusion

In this study we introduce a concept of TTE that builds upon two complementary concepts of PDEs and the 4I paradigm, the call for which has been made by previous research. As a new concept, knowledge on the potential of TTEs as a combination of the above for the use in the public sector, types of policies it can affect and the kind of public value it can create is limited. The results of this study reveals that there is potential for the TTE to generate public value across ministries and agencies generating public value ranging from sustainability to transparency, accountability, efficiency and innovation. Nonetheless, development of pilot projects and operationalization of TTEs is essential to comprehend whether the conceptual cases found in literature can have the expected impact.

Submitted: 31 January 2025, Revised: 26 March 2025, Accepted: 21 April 2025, Published: 22 May 2025

Abstract. The National Pharmaceutical Assistance Policy (PNAF) in Brazil aims to ensure universal access to essential medications through primary care. To achieve this goal and reduce healthcare access inequalities, efficient health system supply chains are crucial. This study evaluates time series forecasting methods, specifically exponential smoothing (ETS) and autoregressive integrated moving average (ARIMA) models, to predict the demand for captopril, a widely used antihypertensive drug, in São Paulo's Basic Health Units. Data on medicine consumption and demand from January 2018 to March 2023 were collected and analyzed to address current inefficiencies in demand prediction, compared through the Mean Absolute Percentage Error (MAPE). Results indicate that the ETS model achieved the best performance in captopril demand forecasting, with a MAPE of 2.26%, significantly improving on the 77.97% MAPE of the existing methodology. Holt-Winters seasonal models and ARIMA also demonstrated robust predictive capabilities, with MAPEs of 3.81% and 3.47%, respectively. This research highlights the potential of data-driven forecasting techniques, such as the ETS model, to optimize resource allocation, ensure medication availability, and improve service quality, providing a framework for future applications in similar contexts.

Keywords: demand forecasting, ARIMA, public health supply chains, exponential smoothing, efficiency improvement.
Policy paper, DOI: https://doi.org/10.59490/dgo.2025.1013

1. Introduction

The National Pharmaceutical Assistance Policy (PNAF), established in 1998 in Brazil, fulfills Article 6 of Law 8,080/90, which mandates comprehensive therapeutic care, including pharmaceutical assistance, within the Unified Health System (SUS) (Brazil, 1990). This policy aligns with the provisions of the World Health Organization, which, has long emphasized that the right to health requires equitable access to essential medicines (WHO, 1978). In this context, the PNAF supports the constitutional principles of universality, comprehensiveness, and equity in health (Brazil, 1988), ensuring essential medicines availability in primary care through municipal supply chains (Oliveira et al., 2010). Lack of access to medicines at this level compromises care delivery (Álvares et al., 2017; Yadav, 2015), therefore, ensuring their efficient distribution is essential to reducing inequalities (Dickman et al., 2017).

However, demand uncertainty poses significant challenges in supply chain management in general (Storey et al., 2006) and is a major issue in healthcare (Subramanian, 2021). Factors like epidemiology and supply shortages are a significant operational barrier for governments managing healthcare supply chains (Dixit et al., 2022). While many causes of medicine shortages are beyond managerial control (Reis & Perini, 2008), better forecasting improves planning and resource use (Subramanian, 2021). Addressing demand distortions is critical, as their effects amplify upstream in the supply chain in a phenomenon known as the bullwhip effect, leading to inefficiency (Lee et al., 1997).

Improving forecasting boosts supply chain efficiency by reducing costs and waste (Al-Zaidi et al., 2018), and

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

enhancing healthcare delivery. In this regard, Saha and Rathore (2024) highlight that innovation and digital tools can support sustainable healthcare supply chain performance. Though underexplored, evidence suggests efficiency gains from adopting demand-oriented healthcare supply chains (Bvuchete et al., 2020). Time series analysis, which consists of analyzing a set of observations ordered over time (Morettin & Toloi, 2004), is one such effective method for forecasting demand (Shah et al., 2023). Its application relies on the premise of serial dependence among data, meaning that future observations are influenced by past behaviors (Villani et al., 2017). Thus, it employs a univariate modeling approach, based solely on time as the input variable (Ackermann & Sellitto, 2022). While no single approach applies universally, healthcare demand forecasting relies on time series patterns—trend, seasonality, cycles, and randomness—for accurate estimates (Soyiri & Reidpath, 2013).

Given this context, this study evaluates the use of time series techniques for forecast captopril demand in São Paulo's basic health units, comparing these forecasts with current models to assess potential efficiency gains in service delivery. It aims to address the scarcity of data-driven tools based on real consumption data in public health systems (Tetteh et al., 2025). Given the role of primary care in reducing health disparities (Starfield, 2001), improving forecasting at the local level—as in São Paulo's municipal system—can inform more accurate planning under real-world constraints.

2. Research Methods

According to Gil (2017), this research is quantitative in data nature, applied in purpose, and exploratory in objectives, having its design carried out through literature review and data collection to better understand the problem presented. The methodology used was adapted from the Cross Industry Standard Process for Data Mining (CRISP-DM) framework (Chapman et al., 2000), applying its first five stages—business understanding, data understanding, data preparation, modeling, and evaluation—while omitting the final stage, deployment, which Schroer et al. (2021) observed is often not included in most studies adopting this process.

Data were requested from the São Paulo Municipal Health Department (SMS-SP), in CSV format, covering monthly consumption and demand of the twenty most dispensed medicines. The selection included medicines purchased directly by SMS-SP and identified as the most dispensed based on the average of the first quarter of 2023. The dataset spanned from January 2018 to March 2023 and included information on month, year, health region, health supervision territory, medicine code, name, demand, and average consumption. This selection aimed to ensure at least one viable time series for the study.

To identify the behavioral patterns of the selected series components, a decomposition method based on moving average filters was applied (Barros et al., 2017). This procedure allows isolating trend, seasonality, and random effects components for graphical visualization. The series were then split into training (January 2018–September 2022) and test (October 2022–March 2023) sets, with predictions evaluated on the last six observations.

According to Choudhary et al. (2022), although machine learning models are increasingly popular for forecasting purposes, classical univariate time series methods, such as exponential smoothing and autoregressive integrated moving average (ARIMA), the two most widely used approaches in time series forecasting (Hyndman & Athanasopoulos, 2021), generally present good results. The use of both model classes was chosen because, although exponential smoothing models perform well for short-term forecasts and for series that do not show severe changes in their behavior, their performance worsens considerably for long-term forecasts, making it interesting to resort to alternatives, such as Box-Jenkins models (Thomaz et al., 2018).

The analysis began with simple exponential smoothing (SES), suitable for stationary series, followed by the Holt-Winters model with linear trend. Additive (HWAS) and multiplicative (HWMS) seasonal Holt-Winters models were then applied to capture both trend and seasonality (Barros et al., 2017). The Error-Trend-Seasonality (ETS) model was also tested using an R function that automatically selects the most appropriate model based on the combination of error (additive or multiplicative), trend (none, additive or multiplicative, with or without damping), and seasonality (none, additive, or multiplicative) (Hyndman et al., 2008; Hyndman & Khandakar, 2008). Finally, the Box-Jenkins methodology was applied using ARIMA models (Ingle et al., 2021), which combine three components: autoregressive (based on past values), integrated (reflecting accumulated effects over time), and moving average (accounting for past forecast errors) (Fattah et al., 2018).

To develop Box-Jenkins models, it is first necessary to assess seasonality and stationarity, applying differencing if required, then identify and estimate the appropriate ARIMA model and evaluate its fit (Wang, 2011). In this study, these steps were performed automatically to identify the optimal ARIMA model based on the Akaike Information Criterion (AIC) and Bayesian Information Criterion (BIC) (Hyndman et al., 2008), which balance model fit and complexity. The lower these values, the better the combination of parameters p, d, and q, corresponding respectively to the order of the autoregressive component, the order of differentiation, and the order of the moving average component (Choudhary et al., 2022).

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

After generating the models, accuracy was assessed using the Mean Absolute Percentage Error (MAPE), which is used to measure the accuracy of forecasting models, through the average of absolute percentage differences between forecasts and actual values (Hyndman & Koehler, 2005). It is calculated as follows:

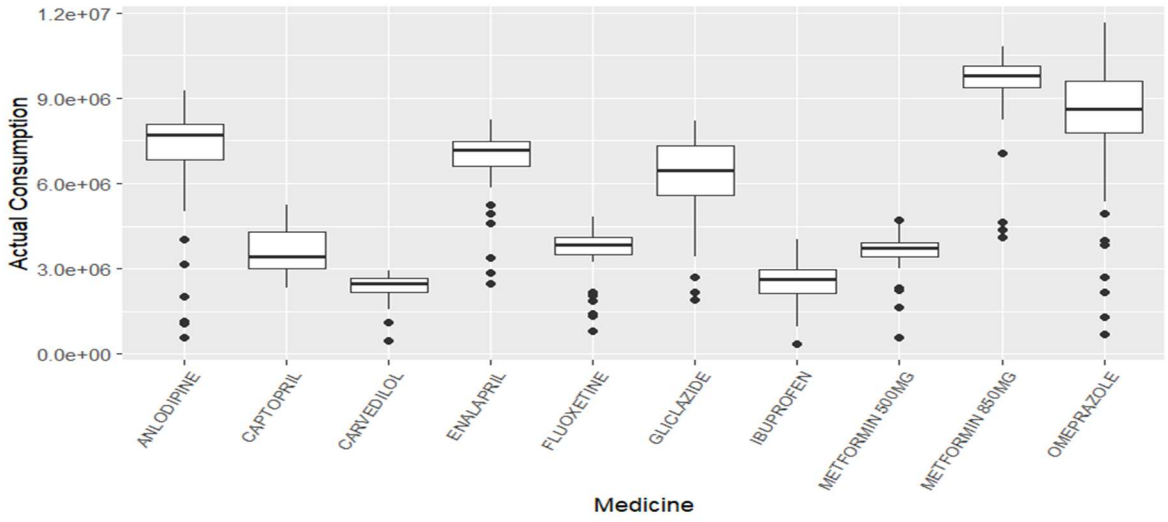
$$\text{MAPE} = \frac{1}{n}\sum_{t=1}^{n}\left|\frac{Y_t - \hat{Y}_t}{Y_t}\right| \times 100$$

where: Yt is the actual value at time t; Ŷt is the forecasted value at time t; Yt - Ŷt is the forecast error, $\sum_{t=1}^{n}\left|\frac{Y_t - \hat{Y}_t}{Y_t}\right|$ represents the sum of absolute errors for each observation divided by the actual values, transforming them into a proportion relative to the actual values which, multiplied by 100, is converted into a percentage error relative to the actual values and $\frac{1}{n}$ indicates the division by the total number of observations n, providing a measure of the mean error in percentage terms.

As all time series values were positive and well above zero, the MAPE was preferred for its simplicity. The model with the lowest MAPE was selected as the most accurate for the case under study.

3. Results

The results will be presented following the CRISP-DM methodology stages.



3.1 Business Understanding

Medicines purchased directly by SMS-SP are distributed from a central warehouse to primary health care units, based on monthly demand values recorded in the inventory system—referred to in this study as *informed consumption*. Although a manual defines this value as the average of consumption over a set number of months (Prodam-SP, 2008), this method is not consistently applied in practice, and the actual calculation remains unclear. Nonetheless, this value is used for supply planning under the current SMS-SP methodology.

Dispensation to patients is also recorded in the system, and the monthly output is referred to here as *actual consumption*. Based on these definitions, the study aims to assess the accuracy of SMS-SP's current demand forecasting approach and compare it with time series forecasting methods using the same data. Considering the scale of São Paulo's operation—over 450 health units across 27, health supervision territories in 6 health regions—the requested data were structured at the health supervision territory level to enable better tracking of discrepancies and support the study's objectives.

3.2 Data Understanding and Preparation

The data request was submitted to SMS-SP on May 4, 2023, and they were provided on June 24, 2023. The file contained consumption and demand data for 20 medicines (January 2018 to March 2023) from 472 primary health care units, organized by territories. These were aggregated by health supervision territory, resulting in a dataset imported into RStudio with information from 27 territories. During data exploration, medicines with fewer than 1,701 observations—due to missing data across 27 territories and 63 months—were excluded to avoid distortions. For the remaining 10 medicines, boxplots (Figure 1) were used to detect outliers and assess pandemic-related impacts on their time series.

Fig. 1 - Boxplot of actual medication consumption from January 2018 to March 2023. Source: Original research results.

Since captopril was the only medication without outliers and showed no significant pandemic-related changes, it was selected for modeling and prediction. The dataset was then limited to this medication. Figure 2 shows the time series of its actual consumption (dispensed quantity) and informed consumption (reported demand).

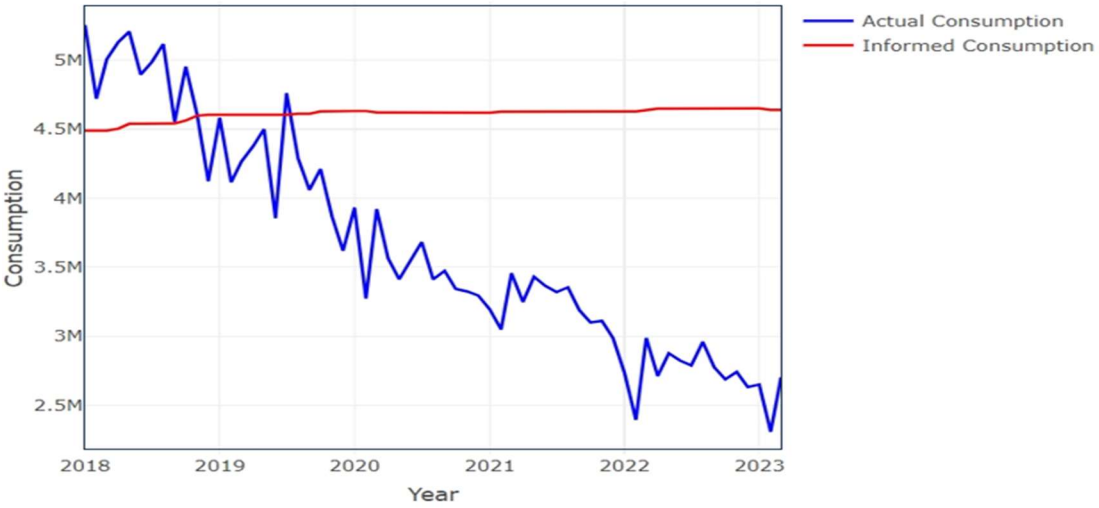

Fig. 2 - Actual Consumption and Informed Consumption of Captopril from January 2018 to March 2023. Source: Original research results

Actual consumption shows a strong downward trend, while informed consumption (forecasted demand) remains more stable. To analyze the components of the time series under study, an additive decomposition method was applied (Hyndman & Athanasopoulos, 2021). Seasonality and a decreasing linear trend can be seen in Figure 3 below.

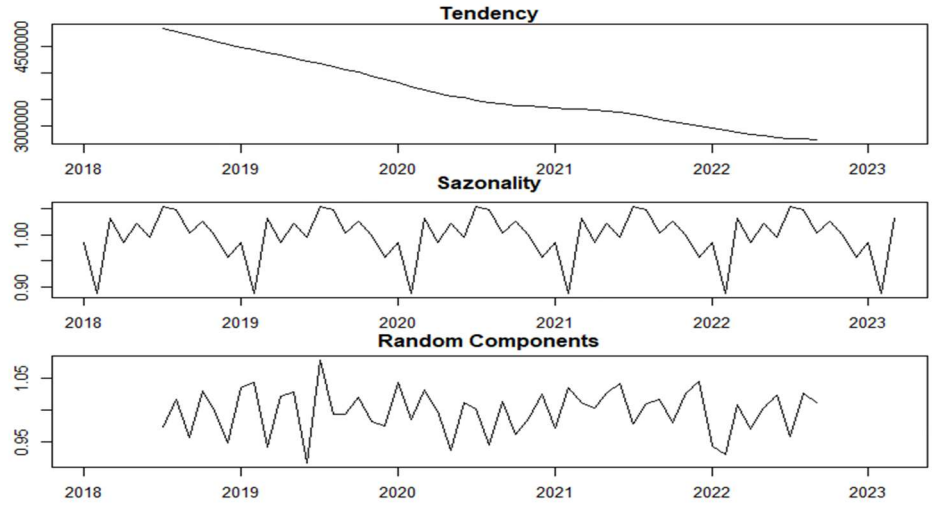

Fig. 3 - Additive Decomposition of the Captopril Actual Consumption Series. Source: Original research results

3.3 Modeling

Modeling started by splitting the data into training (January 2018–September 2022) and test sets (last 6 points: October 2022–March 2023), as shown in Figure 4.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

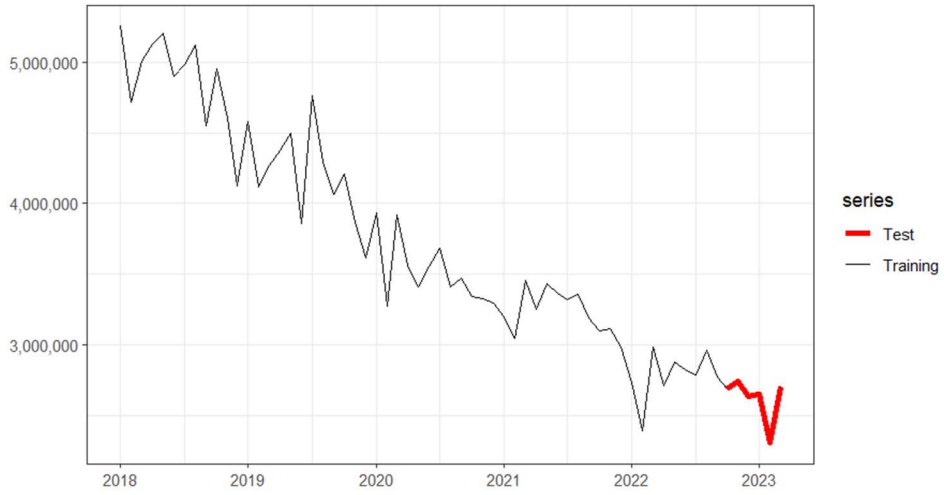

Fig. 4 - Separation of the Captopril Actual Consumption Time Series into Training and Test Data. Source: Original research results.

The MAPE for the original forecast (informed consumption) over the last 6 points was 77.97%, indicating a high average error compared to actual consumption.

The predictions made using exponential smoothing techniques are shown in Figures 5 to 9 below. Figure 5 shows the simple exponential smoothing model; Figure 6, the Holt-Winters trend model; Figure 7, the additive seasonal Holt-Winters model; Figure 8, the multiplicative seasonal Holt-Winters model; and Figure 9, the ETS model.

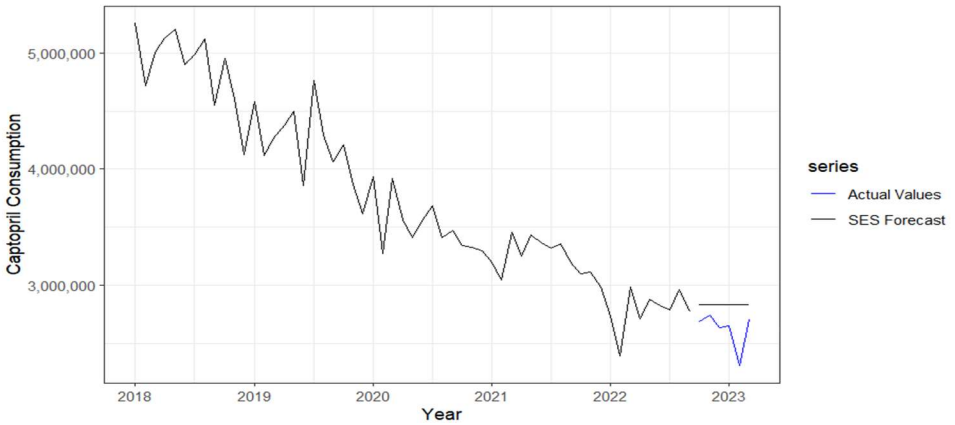

Fig. 5 - Comparison of forecast using the exponential smoothing method with actual values. Source: Original research results.

The last class of models applied was ARIMA. Among these, the most accurate was ARIMA(2,1,0)(1,0,0)(12) with drift, selected based on the AIC criterion, where the lowest value indicates the model with the best balance between fit and complexity (Choudhary et al., 2022). This model includes two autoregressive terms, one differencing, no moving average terms, and a seasonal autoregressive component of order one with a 12-month period. The "drift" term indicates the presence of a linear trend.

Forecasts for the next six months using this model are shown in Figure 10.

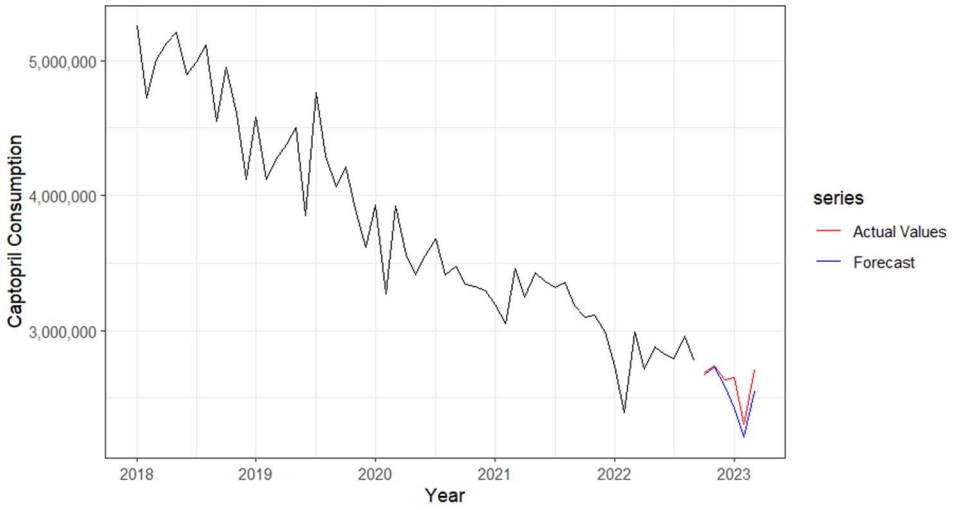

Fig. 10 - ARIMA Model Forecast Compared to Actual Consumption Data. Source: Original research results.

3.4 Evaluation

After applying all models, MAPE was used to identify the best performer. MAPE's simplicity allows direct interpretation without further comparison (Chen et al., 2017). Table 1 shows that the model with the highest predictive capacity for the time series under study was the ETS.

Tab. 1 - MAPEs of Models.

Modelos	MAPE
Previsão atual	77,97
Holt-Winters aditivo sazonal	8,84
Suavização exponencial simples	8,36
Holt-Winters multiplicativo sazonal	4,33
Holt-Winters com tendência	3,81
ARIMA	3,47
ETS	2,26

Source: Original research results

After identifying ETS as the best model, its residuals' autocorrelation was tested using the Ljung-Box test, indicating whether the autocorrelations found are more significant than expected in a random series (Hyndman & Athanasopoulos, 2021). Table 2 shows a p-value of 0.1381, indicating no significant autocorrelation at the 0.05 level. Thus, the residuals are independent, confirming a good model fit. This result indicates the ETS model fits well and outperforms the current model based on MAPE.

Tab. 2 - Ljung-Box Test Result.

Elementos	Valor
X-squared	21.995
df	1
p-value	0,1381

4. Discussion

The results show that time series methods can effectively improve forecast accuracy for captopril consumption in São Paulo's health units, though dataset and modeling limitations should be considered. While this study focused on a stable, complete series, predictive methods can also be applied to series with irregularities, requiring contextual analysis to address anomalies caused by supply shortages or reporting errors—common in public

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

sector supply chains.

This issue is critical in the public sector, where inconsistent operations and stockouts lead to suppressed demand not reflected in the actual consumption data, thereby potentially distorting the time series. Infante and Santos (2007) found that automatic replenishment based on historical consumption is biased by frequent stockouts, while replenishment driven by subjective requests introduces significant errors—findings that align with this study and highlight structural challenges in public supply chains.

Structural constraints—such as limited personnel, bureaucracy, and low local autonomy—continue to hinder public supply chain management. Although Supply Chain Risk Management (SCRM) is essential to mitigate disruptions, its application in Brazil remains limited. Senna et al. (2022) noted that centralized, risk-insensitive decision-making often leads to reactive and fragmented actions, a pattern reflected in this study. This highlights the importance of integrating predictive models with broader institutional strategies to build resilience and coordination.

While univariate models used here improved forecast accuracy, they overlook key drivers of demand such as demographics, disease patterns, policy shifts, and supply issues. Given the growing pressures on Brazil's SUS from epidemiological and technological changes (Elias, 2013), future studies would benefit from adopting multivariate models that incorporate these factors to strengthen planning and responsiveness.

Bhat et al. (2024) highlight the potential of integrating stochastic, causal, and projective forecasting—combined with machine learning and inventory optimization—to improve access, reduce stockouts, and optimize resources in public primary care. These hybrid approaches are promising for decentralized systems, especially when adapted to institutional constraints.

This study reinforces that applying forecasting techniques and digital tools can improve demand prediction, public spending, service efficiency, and equity in access to essential medicines. Beyond practical contributions, the findings add to the theoretical understanding of forecasting in decentralized public supply chains with limited autonomy. While structural barriers are well documented (Yadav, 2015; Dixit et al., 2022), this study offers empirical evidence that even simple models can enhance decision-making in resource-constrained settings.

5. Conclusions

Beyond its practical contributions, this study also provides important theoretical implications for public administration and health policy. It reinforces the relevance of evidence-based decision-making frameworks in public logistics and the need to strengthen institutional capacity to operationalize predictive analytics in decentralized health systems. Moreover, the findings support the view that supply chain transparency and forecasting accuracy are not only technical challenges but also governance issues, requiring alignment between data infrastructure, managerial autonomy, and policy objectives.

From a theoretical standpoint, the study reinforces the role of local-level data analytics as a governance instrument in health policy. It suggests that forecasting is not merely a technical function, but also a strategic capability that shapes how public administrations manage uncertainty and allocate resources. In this context, the results point to the need for public policies that improve access to medications dispensed at the primary care level within the SUS, as shortages can lead to treatment discontinuity and, consequently, an increase in the number of hospitalizations. Failing to address this issue may further burden the health system with avoidable inpatient care resulting from gaps in outpatient treatment (Oliveira et al., 2021).

6. Acknowledgements

- **Data/Software Access Statement:** Data were obtained from the São Paulo Municipal Health Department via formal request and are not publicly available due to institutional restrictions. Analyses and forecasts were performed using RStudio (v2023.12.1+402) with R (v4.3.3) and relevant packages.

Track 4: Digital Democracy & AI

Track Description

AI technologies have significantly expanded the potential to improve democratic services, enhance communication quality, and support data-driven decision-making. By integrating AI in government, the aim ought to be to improve citizen-government collaboration, smart city planning, and other key initiatives that foster informed policy-making. The Digital Democracy & AI track aimed to explore how advancements in AI can enhance democratic processes through collaborative human-machine interactions. More specifically, the goal of this track was to gather insights into how AI can support more inclusive, transparent, and responsive democratic systems, addressing both opportunities and challenges. Beyond diverse topics under the theme, the track chairs also encouraged research exploring the regulation of technology platforms and the ethical use of AI-driven tools in shaping democratic governance.

Abstract. The integration of Generative AI (GenAI) technologies, such as ChatGPT, into online education is accelerating; however, their effectiveness in under-resourced contexts remains insufficiently studied. This paper investigates the impact of a Large Language Model (LLM)-based conversational agent on student engagement and learning outcomes in Afghanistan, where access to formal education—particularly for women—is severely restricted or banned. We conducted an experimental study involving 80 undergraduate computer science students (40 male, 40 female) in Afghanistan, randomly assigned to control and treatment groups. All participants attended identical 50-minute online lectures followed by 40-minute post-lecture discussions moderated by a human instructor, and completed a follow-up self-report questionnaire. The treatment group additionally engaged in AI-facilitated discussions using a GPT-4-based chatbot during post-lecture discussion. Analysis of discussion logs and post-intervention surveys revealed that the treatment group demonstrated significantly higher participation rates, with more posts and replies, during post-lecture discussion and reported greater confidence in their understanding of the course material. These findings highlight the potential of LLM-based chatbots to enhance interactive learning and foster educational inclusion, particularly for marginalized populations in low-resource environments.

1. Introduction

The demand for online learning has surged globally due to limited classroom capacity, rising educational costs, and the need for flexible learning options (Hart et al., 2018) External disruptions such as the COVID-19 pandemic (Szopiński & Bachnik, 2022) and internal political and cultural restrictions in such war-ravaged countries as Afghanistan have further accelerated the shift toward online education (Haqbeen et al., 2023). Afghanistan is currently the only country where women and girls are systematically banned from accessing secondary and higher education due to political and cultural restrictions imposed by the ruling Taliban regime (Haqbeen et al., 2023). Recent surveys in Afghanistan highlight the severe impact of these restrictions on women's educational attainment, with females significantly lagging behind males in learning and academic achievement (Lyons, 2023). This disparity reflects the longstanding gender inequality in access to education in Afghanistan (Shayan, 2015), where

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

women and religious minorities are frequently excluded from male-dominated spheres such as education, politics, commerce, and even public life (Haqbeen et al., 2021).

In response, many Afghan women now rely on online learning opportunities provided by non-profit organizations as their primary avenue for education (Haqbeen et al., 2023). Despite the promise of online education, virtual learning environments often suffer from limited interactivity and student engagement (Singh & Meena, 2022). A lack of meaningful student–student, student–instructor, and student–content interaction during online course is a major drawback, leading to passive learning experiences (Haleem et al., 2022). Large class sizes (sometimes with hundreds of participants) pose additional challenges for maintaining engagement and personalized interaction. Studies have found that increasing online class size can negatively impact instructor–student interaction quality (Sorensen, 2015), and reduce student satisfaction (Russell & Curtis, 2013). Indeed, research shows that interactivity—especially between students and instructors—is a key factor influencing student satisfaction and learning outcomes (Espasa & Meneses, 2010). Active teaching strategies that promote engagement have been shown to improve participation (Deslauriers et al., 2019). Facilitating peer-to-peer learning is considered crucial for the next wave of online education innovation (Chandra & Palvia, 2021). However, in large online classes it is difficult for instructors alone to manage and simulate rich post-lecture discussions among students (student–student, student–instructor, and student–content interaction).

Recently, advances in Generative Artificial Intelligence (GenAI) (e.g., OpenAI's ChatGPT) have opened new possibilities for enhancing online interactivity (Kasneci et al., 2023). Large Language Models (LLMs), such as GPT-4 (Achiam et al., 2023) have demonstrated remarkable abilities in understanding and generating text, quickly establishing themselves as foundational components of many AI-powered applications, particularly in education domain. This technology supported the initiative of LLMapps, which refer to the type of software that uses LLMs as one of its building blocks, have been developed (Yan et al., 2024) in different downstream domains. Downstream refers to application-specific tasks where pre-trained LLMs are used or fine-tuned. For example, using GPT-4 to build an app that helps students write essays. Particulary in LLM-assisted apps in education like, Khanmigo, a GPT-4-based virtual tutor and classroom aide by Khan Academy to help student in their learning process (Anand, 2023).

The LLM-assisted apps can engage learners in dialogue, answer questions, and provide tailored feedback, potentially stimulating student engagement even in the absence of direct human instructors. While such AI tutors and facilitators are increasingly being integrated into educational settings (Kasneci et al. 2023), their effectiveness in low-resource contexts like Afghanistan remains under-studied.

Our work addresses these gaps by introducing an LLM-based conversational agent into online class discussions for Afghan students. We investigate whether a GPT-based powered chatbot, acting as a discussion facilitator alongside a human instructor, can enhance student engagement and improve learning outcomes. We conducted a randomized controlled trial to evaluate the chatbot's impact. We hypothesized that AI-facilitated discussions would lead to higher student participation (more frequent and longer contributions) and greater learning outcome experience compared to discussions led only by a human tutor. The study's focus on Afghan learners (including female students facing educational barriers) provides insight into AI's role in supporting equitable access to interactive learning.

The structure of the paper is as follows: Section 2 presents relevant studies. In Section 3, we detail the methodology, experimental settings, sample and sampling, and implementation of our social experiment. Section 4 presents the results, followed by discussions. Finally, we summarize our work and highlight future directions in section 5.

2. Related Work

Prior research emphasizes that a lack of interaction in virtual classrooms leads to diminished student engagement (Haleem et al., 2022). Another study found that larger online class sizes correlate with lower instructor performance in fostering interaction (Sorensen, 2015). Russell and Curtis, reported that students and teachers perceive less meaningful engagement in large-scale online language courses than in smaller ones (Russell & Curtis, 2013). Espasa and Meneses highlighted the importance of feedback processes in online environments, linking interactive feedback to better learning outcomes (Espasa & Meneses, 2010). Overall, ensuring interactivity in online education is critical to prevent passive learning during online educational course.

To address engagement challenges, various technology-mediated solutions have been explored. Deslauriers et al. demonstrated that actively engaging students in class (e.g., through interactive activities) yields greater actual learning, even if students subjectively feel they learned less (Deslauriers et al., 2019)—underscoring the importance of interactive engagement. Chandra and Palvia discussed the emerging paradigm of peer-to-peer learning in online education, suggesting that enabling students to interact with each other is key to improving outcomes (Chandra & Palvia, 2021). One promising approach to facilitate such interaction in online interaction is the use of conversational AI agents as a facilitator to support online activities (Ito et al., 2022).

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Generative artificial intelligence (AI) is poised to revolutionize how humans work, and has already demonstrated promise in significantly improving human productivity (Bastani et al., 2024). LLMs, such as GPT-4 have demonstrated remarkable abilities in understanding and generating text, quickly establishing themselves as foundational components of many AI-powered applications, particularly in education domain (Achiam et al., 2023). For example, Bastani et al., conducted a field experiment with nearly 1,000 high school students to assess the impact of GPT-4 on math learning. They compared two AI tutors: GPT Base (standard ChatGPT interface) and GPT Tutor (prompt-engineered for learning support), integrated into 15% of the curriculum. While both improved short-term performance (48% and 127%, respectively), the study also found that students who later lost access to the AI performed worse than those who never used it, suggesting potential long-term dependency risks (Bastani et al., 2024).

Our study builds on this work from conservative lenses by applying GPT-4 as a conversational agent in an educational context to support downstream domains such as education. In line with this, we use GPT-based chatbot as facilitator to enhnace student enagement and learning outcome in online education. We rely on mainstream LLMs like GPT-4 as foundational model and tailored for specific post-lecture facilitation task. GPT-4 is a much-improved model compared to GPT-3.5, which is the large language model that powers the now infamous ChatGPT (Achiam et al., 2023).

Our work inspired by prior research on the efficacy of conversational agent in enhancing online discussion performance. Prior research on human-conversational agents behaviour studies suggests conversational agents can improve user interactions, enhance discussion and support minorities in online discussion. For example, Ito et al. developed an agent to facilitate crowd discussions in large groups (Ito et al., 2022). Conversational agents have been shown to increase women's contributions in online debates (Hadfi et al., 2023) and to improve overall engagement and problem-solving in discussion activities (Sahab et al., 2024). Argumentative chatbots can scaffold debates in online forums (Hadfi et al. 2021), and AI facilitators have demonstrated benefits for critical thinking in social media discussions (Tanprasert et al., 2024).

These studies indicate the potential of AI-driven agents to enrich online learning interactions. However, it is unclear how such tools perform in unique online education environments like Afghanistan, where resource limitations differ from typical settings (Haqbeen et al, 2023) can work. Our work addresses this gap by introducing an LLM-based conversational agent into online class discussions for Afghan students to empirically study how a Large Language Model (LLM)-based chatbot influences student engagement and learning outcomes in online courses in a low-resource educational setting like Afghanistan.

3. Methodology

3.1 Research design

The study recruited 80 undergraduate computer science students (40 female, 40 male; aged 18–26) from a pool of 3,432 qualified applicants (out of 3,761 who initially registered) from Afghanistan via local subjects' recruitment agency (Sahab et al., 2024b). A priori power analysis was conducted using G*Power v3.1 (Faul et al., 2009) to assess the adequacy of the sample size for an independent samples t-test comparing two groups (treatment vs. control). With a total of 80 participants (40 per group), the study is adequately powered (power ≈ 0.80) to detect large effect sizes (Cohen's $d \geq 0.65$) at a significance level of $\alpha = .05$.

We conducted a randomized controlled trial (RCT), and participants were randomly assigned to either a control or treatment condition (Sahab et al., 2024b). Each condition had 40 students during online lectures via Zoom, and subdivided into four discussion groups of 10 students each during post-lecture discussion via Discourse. All participants attended identical 50-minute online lectures followed by 40-minute post-lecture discussions moderated by a human instructor, and completed a follow-up self-report questionnaire. The treatment group additionally engaged in AI-facilitated discussions using a GPT-4-based chatbot during post-lecture discussion.

Figure 1 illustrates the recruitment and grouping process. Selected students were randomly assigned into two conditions (control vs. treatment, 40 each). To facilitate post-lecture discussions, each condition was further divided into four smaller discussion groups of 10 students (labeled A1–A4 for control and B1–B4 for treatment). We used stratified random sampling to ensure each discussion group had an equal gender mix (5 female, 5 male per group). All participants provided informed consent and then took part in study.

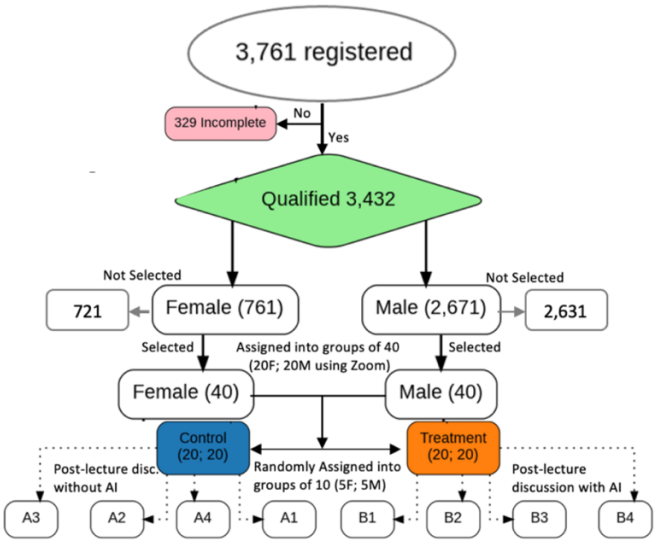

Figure 1. Provides an illustration of the recruitment process and the experimental pipeline.

3.1 Online lecture with follow-up discussion

At the beginning of experiment, both the control and treatment groups (n=80) attended an identical 50 minutes live lecture via Zoom, a videotelephone application which is used for online learning courses. The lecture content was the same for all students and was delivered by an experienced instructor (a Ph.D. in CS with >2 years online teaching experience). To maintain consistency across conditions, the lecture topic and materials were fixed: a lesson on "The Role of Information in Society." The instructor used the same slide presentation and script on both days to minimize any variability in instruction. Each lecture lasted approximately 50 minutes. By controlling all instructional content and delivery, we ensured that any differences observed between conditions could be attributed to the discussion facilitation method (with vs. without the AI chatbot) rather than differences in teaching.

Following the lecture, students were divided into groups of ten (5 female, 5 male per group), resulting in four discussion groups per condition (treatment and control) and engaged in a 40 minutes post-lecture discussion session conducted via an online customized discussion forum called Hyper-Democracy platform, which is built on the open-source Discourse system (Ito et al., 2024; Discourse, 2025). Each group's discussion space was supervised randomly by the same course instructor, who served as the human facilitator across both conditions.

In each condition group (n = 40), a single instructor was assigned to facilitate both conduct the Zoom lectures and interact (moderate) the subsequent post-lecture discussions. These discussions were conducted in smaller breakout groups, with 10 students per group across four subgroups. The instructor rotated between these groups at random intervals. This setup was designed to reflect the practical challenges instructors face in large-scale online courses, particularly the difficulty of independently managing and stimulating meaningful discussions across multiple simultaneous groups.

In the treatment condition, an AI chatbot facilitator was integrated alongside the instructor to support and stimulate the conversation. In contrast, the control condition relied solely on human facilitation by the instructor. This setup ensured that all participants took part in an online discussion following the lecture, with the key distinction being the presence or absence of AI facilitation.

The discussion session was structured to prompt reflective engagement around the guiding question: "What are the key takeaways from today's lecture?" To facilitate meaningful post-lecture discussion, the session was divided into three clearly defined phases:

1. Key Point Generation (15 minutes): Participants were encouraged—by the human facilitator (instructor) and/or the AI agent—to identify and articulate the most significant concepts presented in the lecture.

2. Bridging Theory with Practice (15 minutes): Participants were encouraged—by the facilitator and/or the AI agent—to connect lecture content with real-world contexts or personal experiences.

3. Summary and Forward Reflection (10 minutes): Participants were encouraged—by the facilitator and/or the AI agent—to summarize the discussion, extract key insights, and offer feedback or suggestions for future topics.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

This structured format was designed to ensure consistency across conditions and to allow systematic analysis of the AI facilitator's impact. The overall experimental procedure is summarized in Figure 2.

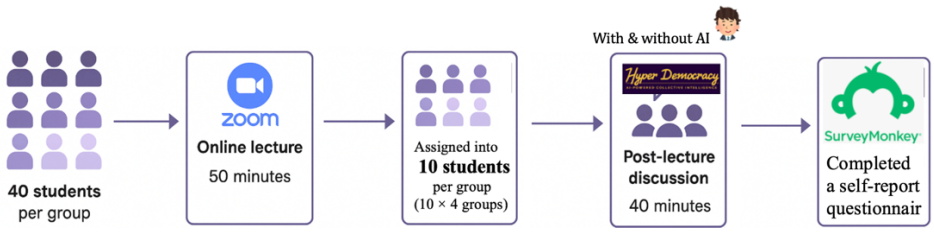

Figure 2. The main experimental pipeline.

3.2 Chatbot Design and Deployment

The conversational agent used in the treatment condition was implemented using the OpenAI's GPT-4 (Achiam et al., 2023). To ensure the chatbot's interventions were relevant and pedagogically useful, we employed a few-shot learning and prompting approach (Tunstall et al., 2022) during its development. We used the GPT-4 model behavior by providing several example question-answer pairs related to the lecture content and discussion guidelines. To ensure both coherence and contextual appropriateness in agent responses, we implemented a predefined prompt adaptation and learning strategy (Liu et al., 2023). Instead of prompting GPT to generate sentences from scratch, we curated a structured set of facilitation messages (a set of 17 human-authored facilitation messages) in advance for post-lecture discussion session while adopting three clearly defined phases explained in section 3.1. During interactions, the agent leverages GPT to post exact facilitated messages which pre-defined by human author or dynamically modify these predefined sentences to better align with the ongoing discussion. This indicates that the chatbot does not always generate messages autonomously; rather, it draws on previously authored human facilitation posts as references. In Figure 3, red-bordered box shows the chatbot's posted previously written human-authored facilitated message, and blue-bordered box a conversation between a student and the chatbot, where chatbot posted a facilitated message entirely created on its own based on posted examples. This design balances the need for consistency in facilitation objectives with the flexibility required to respond to context-specific dialogue. In essence, GPT is not tasked with creating new content but with adapting existing prompts to fit the evolving conversational context. We adjusted the phases for chabtot facilitation described in section 3.1 based on time.

To integrate user (students) interactions with AI agent during post-lecture discussion, we deployed the chatbot into the Discourse (Ito et al., 2024), so the participant could post messages and replies in the discussion threads. On the backend, the chatbot listened to the discussion in real time via the forum's API and decided to intervene once it sees posted messages. On the frontend, the chatbot's profile name was explicitly set as "Facilitator", and the chatbot's profile picture was set similar to those from the popular Japanese "Irasutoya" site (Irastutoya, 2025), which is often used for free educational or presentation illustrations.

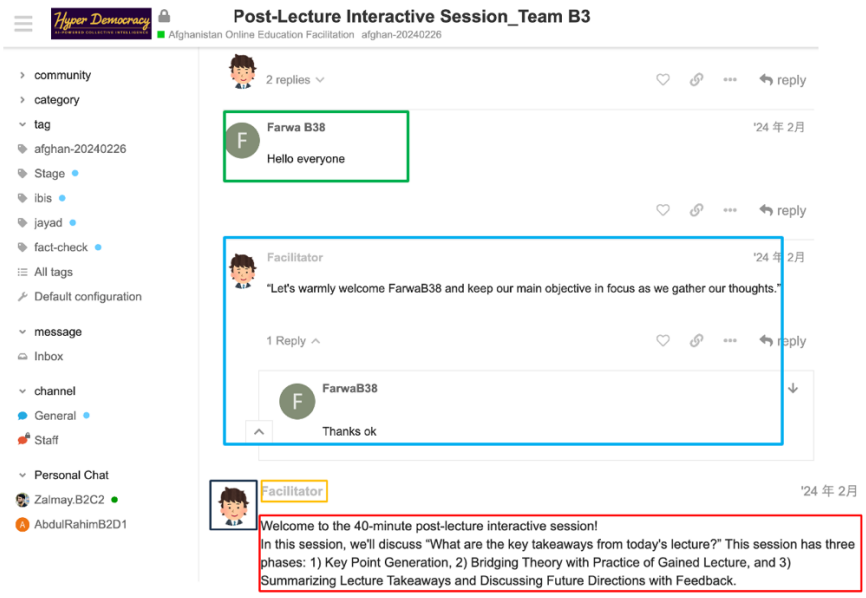

Figure 3. The main user interface of the post-lecture discussion website featuring AI-facilitated interaction (Treatment).

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

In Figure 3, the interface illustrates a structured online discussion session conducted with treatment group. The green-bordered box at the top shows a message posted by a human participant. Below, the blue-bordered section represents a human–chatbot interaction, in which the AI facilitator acknowledges the participant and encourages focus. On the left, the dark blue-circled avatar depicts a cartoon-style profile image similar to those from the popular Japanese "Irasutoya" site representing the AI facilitator. The orange-highlighted label indicates the chatbot's displayed role "Facilitator". Finally, the red-bordered box shows the chatbot's posted human-authored facilitated message.

3.3 Data collection and analysis

We logged all discussion activity on the forum for both conditions. Each student's posts, replies, word-count, and likes were recorded, along with chatbot facilitated messages (treatment groups), timestamps and thread structure. To evaluate student-student engagement and discussion performance, we defined quantitative metrics based on prior research on online discussions (Hadfi et al., 2023; Sahab et al., 2024a): (1) Posts per user – the average number of messages each student posted; (2) Replies per user – the average number of direct replies to others' posts; (3) Word count – the total number of words contributed by each student, and length of posted messages; and (4) Likes received – the number of "likes" each student's posts received from peers. Among these indicators, the number of posts, replies, and total word count reflect active participation and the depth of discussion, whereas likes primarily signal peer appreciation (Gao, 2016; Schreiner & Fischer, 2021) and are therefore considered light contributions. Metrics were computed to observe any changes or learning effects.

In addition to log data, we administered a short post-experiment survey at the end. This survey assessed students' self-reported learning outcomes and perceived confidence in the subject matter. In particular, we asked students to rate their agreement with the statement: "As a result of this class setting, I feel more confident in this area of study." on a 5-point Likert scale (1=Strongly Disagree, 5=Strongly Agree). We used the 5-point Likert scale to determine the attitudes of individuals towards acceptance study setting. The Likert scale, developed by Rensis Likert in 1932, is a reliable and valid method for measuring attitudes (Sullivan & Artino, 2013). The aim was to capture whether the students felt the discussion format (with or without AI) improved their confidence and perceived learning outcome in the subject.

For analysis, we compared the control and treatment groups on the engagement metrics and survey results. We used independent-samples t-tests to assess differences between conditions for each metric, as well as for the self-report ratings. Statistical significance was set at $p < 0.05$. All quantitative analyses were performed using IBM SPSS Statistics (v28). Below, in section 4, we report the results.

4. Results

4.1 post-lecture discussion engagement

Figure 4 summarizes the post-lecture discussion performance metrics for the control vs. treatment groups.

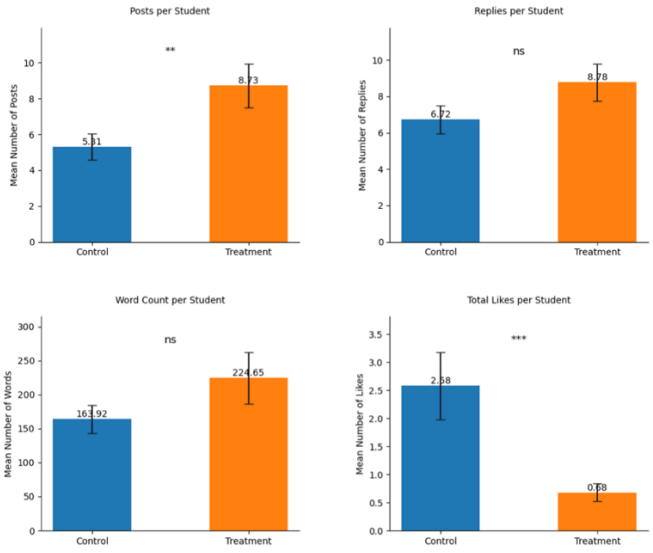

Figure 4. Discussion engagement metrics between control (n=36) and treatment (n=40) groups.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Our finding suggests that treatment group posted significantly more messages per student than the control (p<0.01), while differences in replies and word count were not significant (ns). The control group received more likes per student (*p<0.001). Treatment group students made an average of 8.73 posts each, significantly exceeding the control group's 5.11 posts per student (t test, $p < 0.01$). This indicates that the chatbot's presence stimulated students to contribute more frequently to the discussion. For the other engagement metrics, the treatment group demonstrated a slightly higher mean number of replies per student (8.78) compared to the control group (6.72), as well as a greater average word count per student (224.65 vs. 67.92). However, these differences were not statistically significant. An interesting finding was that control group posts received significantly more "likes" from peers on average than treatment group posts (2.88 vs. 0.78 likes per student, $p < 0.001$).

4.2 Self-reported learning outcome

To assess students' perceptions of their learning experience, we compared the post-experiment survey results between the two conditions. Figure 5 presents the distribution of responses for the control and treatment groups. Overall, students who participated in the AI-facilitated discussions reported higher confidence in their understanding of the course material. The treatment group's average rating was higher than the control groups. An independent t-test confirmed that this difference was statistically significant (t(78) = –2.125, p = 0.037).

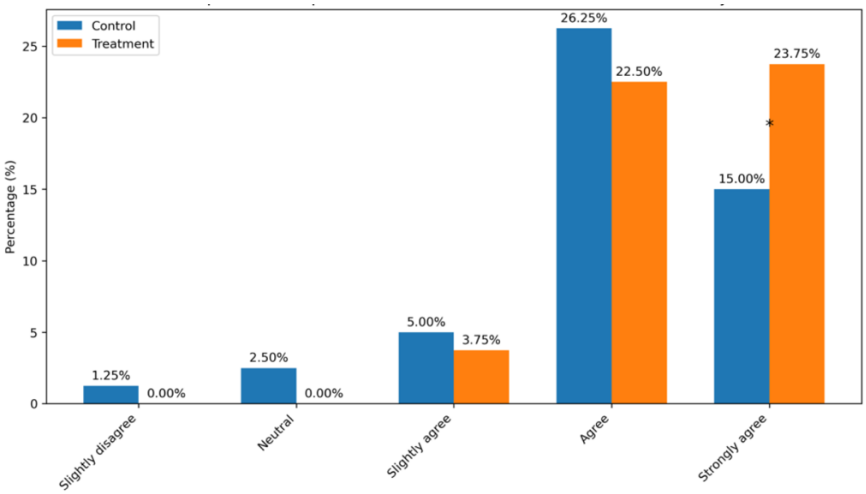

Figure 5. Comparison of post-intervention self-report measurement responses of users between control (n=40) and treatment (n=40) groups.

5. Discussion and Conclusion

In this study, we investigated the impact of an GPT-based AI conversational agent on student engagement and learning outcome in an online course interactive session in Afghanistan. Using a controlled experimental design, we found that embedding a GPT-4-based chatbot facilitator into post-lecture discussions significantly improved multiple facets of student engagement. Analysis of discussion logs and post-intervention surveys revealed that the treatment group (discussion with the AI facilitator) demonstrated significantly higher participation rates, with more posts and replies, during post-lecture discussion and reported greater confidence in their understanding of the course material.

An interesting observation emerged regarding the number of "likes" received across conditions. Posts in the control group (discussion without the AI facilitator) received more likes from peers than those in the treatment group. One possible explanation is that the human-only discussions in the control group resulted in fewer overall posts, allowing students to focus their attention—and consequently their likes—on a smaller number of contributions. In contrast, the higher volume of posts in the treatment groups, facilitated by the chatbot, may have diluted peer attention across more content. This interpretation aligns with the *bandwagon effect* (Schmitt-Beck, 2015), wherein individuals are more likely to endorse content that has already received visible support. In the control condition, where engagement was relatively lower, students may have shown their support through likes rather than additional contributions (*posts* & *replies*). Conversely, in the treatment groups, the chatbot's active facilitation may have encouraged more students to participate directly by posting (*posts* & *replies*), reducing their reliance on passive indicators of engagement such as *likes*.

In this study, our primary focus was on active participation and content engagement, as these measures provide a more meaningful indication of learning involvement (Gao, 2016; Schreiner & Fischer, 2021). Specifically, we emphasized students' efforts to articulate their opinions by posting, rather than merely expressing feelings or

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

offering surface-level reactions by liking. In summary, these results confirm that the chatbot had a strong positive effect on student engagement in the post-lecture discussions.

These finding are further supported by self-reported questionnaire data, which indicated that students who participated in chatbot-facilitated discussions reported higher levels of confidence in the subject matter compared to those in the human-only condition. The higher self-reported confidence in the treatment group on subject matters also merits AI role as a facilitator in discussion. Students in the AI-supported discussions felt more confident about the study material, which is consistent with research showing that interactive and responsive learning environments improve student self-confidence and satisfaction (Pence, 2022). Chatbot likely contributed by promptly addressing confusion and keeping the discussion productive, thus reinforcing students' understanding. Taken together, the survey results reinforce the behavioral data (discussion logs), highlighting the value of AI-assisted facilitation in enhancing student engagement and perceived learning outcomes.

Our findings are in line with emerging evidence that facilitating peer learning can enhance educational experiences (Chandra & Palvia, 2021), interactive and responsive learning environments improve student self-confidence and satisfaction (Pence, 2022), and AI facilitators can amplify the voices and opinions in discussions (Hadfi et al., 2023, Sahab et al., 2024b), and overall support engagement opportunities (Sahab et al., 2024a).

Despite these findings, the study has several limitations and should be addressed in future research. First, while the sample size in our study is adequately powered (power ≈ 0.80) to detect large effect sizes (Cohen's $d \geq 0.65$) at a significance level of $\alpha = .05$. However, it is underpowered to detect medium ($d = 0.50$) and small ($d = 0.20$) effects, for which the estimated power falls below the conventional threshold of 0.80. This limitation should be considered when interpreting non-significant results. Additionally, the study was limited to a single-day intervention with computer science undergraduates considering one environment. Future research should consider replicating the experiment over multiple sessions across different educational programs and areas to examine the consistency and generalizability of the observed effects. Another limitaiton of this study is the chatbot was configured to support multiple facets of engagement: instructor–student interaction (by answering questions or providing prompts), student–student interaction (by encouraging students to respond to each other), and student–content interaction (by bringing in relevant points from the lecture). However, this study focused exclusively on student–student interactions. Future research should explore additional dimensions of interactivity, such as student–instructor and student–content interactions, to assess the consistency and generalizability of the observed effects.

In conclusion, our study provides empirical evidence that AI-powered conversational agents can play a supportive role to enhance student-student interactions in online education. The GPT-based chatbot in our study functioned effectively as a facilitator during post-lecture discussion. These results are among the first to demonstrate such benefits in an Afghan educational setting, suggesting the approach holds promise for other resource-constrained environments. While our study focused on student-to-student interactions, future work will explore the impact of AI facilitation on student–instructor and student–content interactions. We believe integrating AI agents across these dimensions could further optimize online learning experiences. An extended version of this research, including qualitative analysis of discussion content, is in preparation for submission to the IEICE Transactions on Information and Systems.

Abstract. Public speech from government figures often describes relevant actions that can impact the population's lives. However, most people do not have time and access to analyze and understand public speech. Such a scenario narrows the participation of the people in the main discussions, which leads to multiple misunderstandings. In this work, we propose GoViz, a tool that automatically produces visual representations to outline governmental speeches regarding the subject, its main actors, and how they connect to the discussion topics. GoViz processes natural language from speech transcriptions in a pipeline that identifies part-of-speech elements, named-entities, and the relation between persons, making speech content more accessible and insightful. Using publicly available data, we evaluate our tool in two different languages (Portuguese and English). The results demonstrate that the visualizations from both data facilitate understanding the speech content. Thus, our main contribution is to encourage the participation of citizens in parliamentary issues, allowing a simplified and visually engaging avenue to access long speeches and fostering improved communication between parliamentarians and the population.

Keywords. natural language processing, data visualization, digital government
Research paper, DOI: https://doi.org/10.59490/dgo.2025.954

1. Introduction

Most representative democracies define and discuss laws and public measures in parliaments. There, politicians elected by the people vote and argue in favor of the interests of their voters. Although these politicians are the ones to accomplish and propose discussions, the public must also follow and question the decisions and which topics must be covered. However, the language used in these discussions and the decisions made are often hard to comprehend, making them inaccessible to the population. In the analysis of Bernardes and Bandeira, 2016 about parliamentary websites in Brazil and the United Kingdom, one of the main problems found is that even though there is a lot of information available, it can be an exhaustive task to explore and understand such information. Thus, although there is information about these discussions, they still cannot reach the population in a way that facilitates understanding.

A simple way to facilitate the understanding of parliament discussions is through visualizations. Generating images and interactive charts showing the main topics in a discussion can make it easier to follow them. Existing approaches (Cantador et al., 2021; Palma et al., 2021) propose generating visualizations from debates that try to explain most of the discussion. However, they often need extra information from someone who already knows about the subject to guide the generation of these visualizations. Considering that most people do not know about the topic, one of the main features of a visualization tool should be the capacity to process information without any previous knowledge about it.

The Global Parliamentary Report (Inter-Parliamentary Union, 2022) defines the parliamentary engagement in five different points: (1) information, (2) education, (3) communication, (4) consultation, and (5) participa-

tion. The citizens' engagement starts with understanding what is happening in the government. In this work, we introduce GoViz, a visualization tool that automatically processes discourses to provide insightful visualizations that facilitate their analysis. Our main objective with GoViz is to provide a practical application of natural language processing combined with visualization techniques to engage the citizens at the information level. Alternatives like this are necessary because more than making information publicly available is needed. It is necessary to grant that the information is relevant, reliable, timely, and comprehensive, and mainly that it can be understood by everyone in society, regardless of their background, status, or abilities (Inter-Parliamentary Union, 2022).

GoViz uses natural language processing to detect different patterns in speech transcriptions. It can receive structured documents as input and automatically identify columns containing speech and those containing people's names. By connecting people's names with their discourses, GoViz can reveal the main subjects discussed by every speaker and how frequently they talk about other people. Currently, GoViz can work with both English and Portuguese languages, which allows the processing of different types of texts. We evaluate GoViz using two publicly available datasets, one in English and the other in Portuguese. They bring political discussions about sensitive topics that are of people's interest. We perform a series of analyses of the generated visualizations and describe how they connect to the main subject of the datasets and their main limitations.

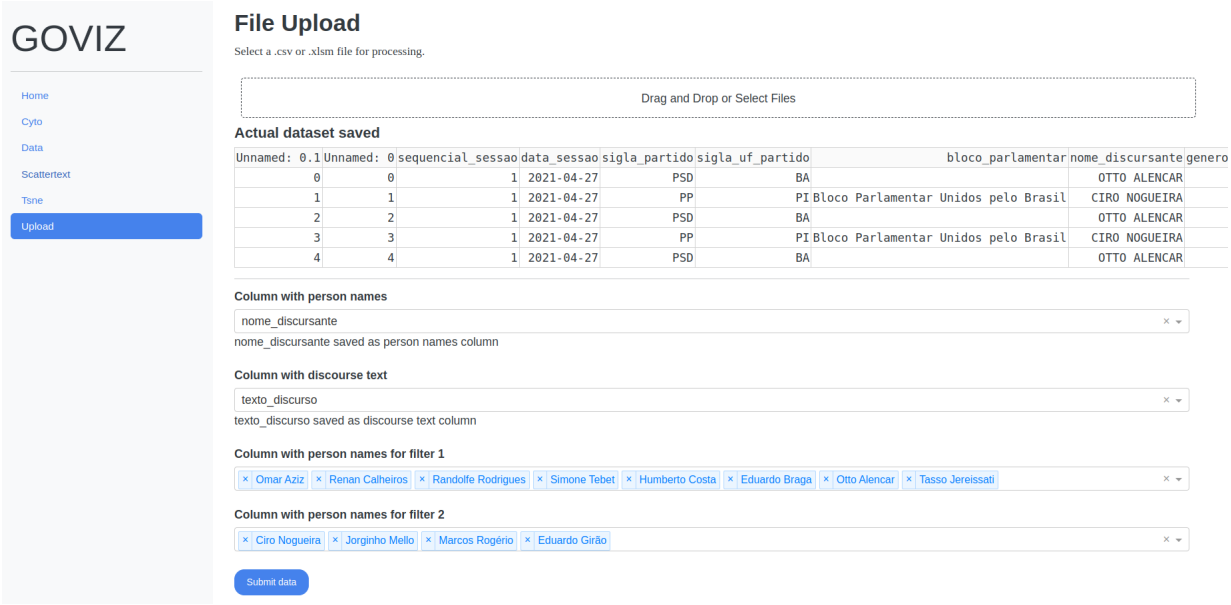

Fig. 1 – Upload screen.

GoViz's contribution is two-fold: first, it increases the direct participation of citizens in parliamentary issues through access to long speeches in a simplified and visual way; and second, GoViz implementation code is publicly available on https://github.com/NLP-PUCRS/GoViz, which allows other people to modify it to work in different contexts and languages. This paper is organized as follows: Section 2 introduces the main concepts concerning this work, such as natural language processing and visualization techniques. We also present some related work that shares some aspects with our approach. Section 3 describes the methods used for building GoViz. Here, we explain how we build GoViz, detailing its different models. In Section 4, we describe the main experiments and the results obtained. We introduce the scenarios and how we extract information from the selected datasets. Given our results, Section 5 discusses the main findings of this work and its limitations. Finally, in Section 6, we summarize our work and bring some perspectives on future work.

2. Background

GoViz is a tool built on two main concepts: Natural Language Processing (NLP) and Data Visualization. From NLP, we leverage the main techniques for extracting textual information. On the other hand, from data visualization, we use existing approaches for summarizing information into visual representations. In this section, we detail the visualization concepts and present related work.

2.1. Text Visualization

When performing data analysis, extracting information from textual data can be difficult. As text can carry relevant information, it is necessary to identify where this information is and how we can summarize it. Text visualization techniques can help with this task. We can consider visualization as a method for communicating information through an image or interactive chart (Ward et al., 2015). Such an image or chart can carry as much information as possible, making it easier for a human to understand the context it is describing. Text visualizations have corpora as a basis and can focus on words, sentences, paragraphs, or entire documents.

One of the first steps to process text is converting it into vector space. In the vector space, we have information about the presence and frequency of words in sentences/documents. There are many ways to obtain a vector that represents a text. Counting the frequency of terms (bag-of-words) in a text is one of the most basic ways to get a vector. Each position in the vector will represent a word with a number indicating the frequency of such a word. With this initial representation, we can already create visualizations that show frequent terms in a text. Other representations can involve the frequency of words in a document weighted by their presence in other documents in a corpus, such as Term-Frequency inverse Document-Frequency (Rajaraman & Ullman, 2011).

A common way to visualize a document is by displaying the frequency of words. Word cloud is a visualization technique that shows the word frequency of a document. It highlights more frequent words by increasing its font size and color darkness (Ward et al., 2015). The result is a cloud-shaped structure containing such words. Similarly, Word Tree is a technique that shows the frequency of words and the context in which they are inserted and allows easy exploration (Wattenberg & Viégas, 2008). Thus, given a document and a target word, it provides a visualization where the target word is the root and the sentences where it appears are the branches.

These techniques demonstrate how we can organize textual information to understand the context without reading it. In addition to Word Cloud and Word Tree, other text visualization techniques can support the representation of connections in the text, such as the arc diagram (Heer et al., 2010), or analyze feature values across the text, such as the literature fingerprinting presented by (Keim & Oelke, 2007).

An alternative to visualize text representations and other high-dimensional elements is using t-SNE (Van der Maaten & Hinton, 2008). This technique allows the visualization of multidimensional points in two or three dimensions. When converting from a multidimensional to a two-dimensional representation, t-SNE can preserve the approximate distance between similar points and non-similar ones. Modifying the concept of Stochastic Neighbor Embedding (SNE) (Hinton & Roweis, 2002), t-SNE proposes a new method to identify the similarity of low-dimensional points using the Student-t distribution. Besides, they propose a new cost function to approximate the real distance between points of low-dimensional representations converted from high-dimensional ones. In this work, we use text visualizations to facilitate people's understanding of speeches from politicians.

2.2. Related Work

Transparency, participation, and collaboration can be considered the principles of the open government (o-government) (Harrison et al., 2011; Quintero-Angulo et al., 2020). Transparency is crucial in making it possible for citizens to participate and collaborate with the government. However, making large datasets publicly available is not enough. This data must be accessible, clear, and easy to understand for citizens. Government data can have different formats and sources. It can be financial values, statistical, and textual, such as speech transcriptions. Manual summarization and information retrieval from textual data are laborious tasks since it is necessary to read everything to understand the subject of the data. Thus, NLP becomes a valuable alternative to extract information from texts automatically.

There are several research initiatives to facilitate the comprehension of a textual dataset, such as chatbots that extract only the desired information (Cantador et al., 2021) and the application of topic mapping from text (Palma et al., 2021). However, these approaches still require prior knowledge of the subject to extract information correctly.

When we refer to speech transcriptions, specifically of debates and public discussions, we can use data visu-

alization techniques to facilitate the understanding of their subjects or to extract key information from these discussions. Khartabil et al., 2021 propose a tool for argument visualization that allows us to determine which points each person is defending. The authors proposed three novel visualizations: Stacked Boxes, Sunburst Pop-Up, and F+C Icicle. Their approach is suitable for deep analyses but requires the user to pass some arguments. Our approach focuses on providing a lean summarization of the content from speech transcriptions.

When analyzing speeches from politicians, it is important to see the agreements and disagreements in political discussions (Volkovskii & Filatova, 2022) and polarization (Diaz et al., 2022). With this information, citizens can use their critical sense and build their vision about the subject in discussion. To facilitate the visualization of different points of view, graphs such as the scatter-text proposed by Kessler, 2017 allow us to compare two groups of people. The scatter-text allows us to clearly see the polarization between two groups and which terms they commonly address. Because of this, we have incorporated this type of graph into our tool. Its use is available when processing documents in Portuguese and English.

Focusing on open government data, Steinbauer et al., 2016 and Bönisch et al., 2023 propose visualizations to explore transcribed parliamentary speeches. Steinbauer et al., 2016 explores Austrian parliament data, proposing a tool to visualize the relationships between politician discourse and parliamentary groups. The authors present the politician's profile and overview through visualizations, including the politician's speech, club, absence, and a politician relation graph in the parliament. While Steinbauer et al., 2016 uses the sentiment expressed in the speech towards topics discussed, we analyze the content of the speech to define the relations. Bönisch et al., 2023 proposes a web application to explore the minutes of plenary proceedings, agenda items, and polls of the German government data. The proposed tool contains a topic analysis, focusing on a specific speaker, party, or fraction on a specific topic. The Deputy Inspector analyzes a speech in conjunction with complementary data from background information, remarks, and poll results. In contrast to Bönisch et al., 2023 tool, which is specific to German government data, our tool is generalist, accepting various sources of data in Portuguese or English.

3. GoViz Description

In this section, we describe the methodology used to develop GoViz. We explain the data input supported, the main techniques used to process the text, and the available visualizations to analyze it. Figure 2 illustrates all the processing stages described in the following sections.

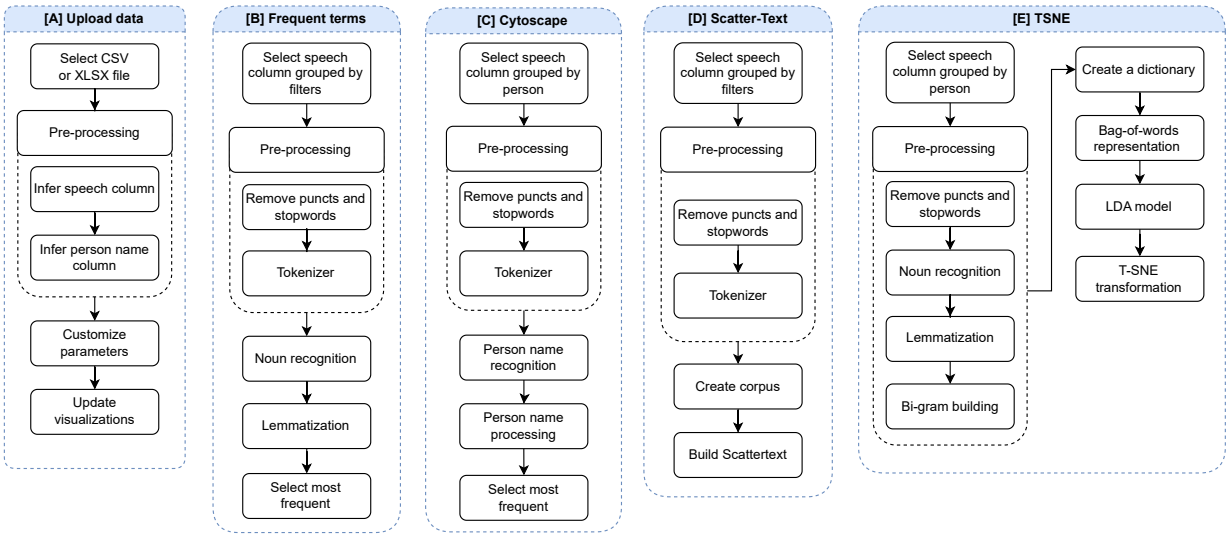

Fig. 2 – Processing stages for chart generation.

3.1. Methodology

For this work, we initially analyzed related work involving the visualization of governmental data. Then, we studied NLP methods and visualization techniques to specify the requirements and functionalities of GoViz.

With this initial study, we defined the type of information we aim to extract from governmental speeches and which NLP models we would employ to obtain them. Finally, given the textual information from the speeches, we selected the best visualization techniques that allowed us to summarize the data.

We process textual data using SpaCy (Montani et al., 2020) and Gensim (Rehurek & Sojka, 2011), while for manipulating the dataset, we use Pandas[1]. For the visualizations, we use the Plotly library[2] to plot the graphs and Dash[3] to build the tool. For this work, we use Spacy for most natural language processing tasks. We selected this library due to its ability to process different languages accurately. Since we want GoViz to work on both Portuguese and English properly, Spacy became a reliable option. Spacy provides the obtained accuracies for each task in different languages. We summarize the results in Table 1. As we can see, both languages have an accuracy higher than 95% for both Tokenization and Part-of-Speech Tagging, while having an F-score higher than 85%. We can see the full results for English[4] and Portuguese[5] in their page. As source for training the models, Spacy uses OntoNotes 5[6], ClearNLP Constituent-to-Dependency Conversion[7], WordNet 3.0[8], and Explosion Vectors (OSCAR 21.09 + Wikipedia + OpenSubtitles + WMT News Crawl)[9]. While for Portuguese, they use UD Portuguese Bosque v2.8[10], WikiNER[11], and Explosion fastText Vectors (cbow, OSCAR Common Crawl + Wikipedia).

Language	Task	Result
English	Tokenization	1.0
	Part-of-Speech	0.97
	Named Entity Recognition	0.85
Portuguese	Tokenization	1.0
	Part-of-Speech	0.97
	Named Entity Recognition	0.89

Tab. 1 – Spacy results for NLP tasks in both English and Portuguese. For both Tokenization and Part-of-Speech Tagging, they provide an accuracy result, while for Named Entity Recognition, they use F-score.

3.2. Input data

The main idea behind the proposed approach is that the user can use different textual datasets to generate visualizations to extract information without the need to read the entire transcription. Textual data can be collected from various sources and stored in different ways. Providing a standard input format is essential to allow a correct visual representation. Thus, GoViz accepts structured data in `csv` and `xlsx` formats. The dataset must contain a column with the person's name and one with textual data. Since our goal is to generate visualizations from speeches, it is important to have information about who is saying the transcribed text. Regarding the textual language, it can be either in Portuguese or English.

To facilitate the use of GoViz by its users, we built an interface, illustrated in Figure 1. It contains an upload function that receives a `csv` or `xlsx` file as input. Once the file is uploaded, we process the textual data using SpaCy and Gensim. Different processing is done for each visualization, as described in Figure 2. We store the processed data in a JSON file that GoViz reads to generate each chart every time the application starts.

3.3. Processing stages

GoViz has five main processing stages. The first one processes the uploaded data. Initially, GoViz pre-processes the uploaded file to infer columns that contain the name of the speaker and the one containing the speech. However, the user can change the automatically selected columns if the inference fails to find them correctly. To

[11]https://figshare.com/articles/dataset/Learning_multilingual_named_entity_recognition_from_Wikipedia/5462500

make the inference, we first convert the dataset into a Pandas DataFrame and verify the column type, removing everything with a data type other than text. From the remaining columns, we select the one containing the largest textual length as the speech column. Once selected, we use SpaCy to perform named-entity recognition on the other columns to identify the person's name column. We select the first word from each row in a candidate column and check if it is a named-entity object identified as a person. The column with the highest occurrence of person names is then selected. Before submitting the data for the next stages, the user can define two groups of person names to compare their speeches. Figure 2[A] illustrates the steps from the first processing stage.

A simple way to identify patterns in textual data is by obtaining the frequency of words. We select data from the provided file based on the groups defined in the data upload stage to extract the frequency of terms. If the user did not provide any groups, we consider the top terms from the automatically identified column containing textual data. When defined by the user, we split the text based on the two informed groups. First, we remove stop words and punctuations to pre-process and convert the raw text into tokens to feed the Spacy model that performs part-of-speech tagging. We only consider nouns for counting the term frequency, as they contain more relevant information, such as things, places, and persons. After filtering the terms, we convert them to lemmas and select only the top 20 most frequent nouns. We illustrate this processing stage in Figure 2[B].

We process data for the third processing stage to obtain the person's names mentioned in each speech. First, we group each speech by the speaker. Then, we pre-process the data by removing punctuation and stop-words and convert it into tokens. We feed the named-entity recognizer Spacy model with the cleaned data. From the output, we keep only the tokens recognized as Person entities. Finally, we get the people's names cited by their frequency. Figure 2[C] shows the steps of this processing stage.

To generate the Scatter-text visualization (see Section 3.4), in the fourth processing stage, we need to create a corpus of frequent terms for two separate groups. This process only occurs when the user previously indicates two groups for comparison. The idea is to visually compare the main terms that each group brings into the discussion. Thus, given each group's speeches, we first use the same pre-processing steps described in the previous stages. Then, using the library provided by Kessler, 2017, we create a corpus containing tokens that we will use to create groups of words and the most frequent terms mentioned by the participants of each group. Figure 2[D] shows the steps to perform this processing stage.

Finally, the fifth processing stage manipulates textual data to serve as input to the t-SNE model (see Section 3.4). In this process, the first step is to pre-process speeches by selecting them by their speaker. Then, we remove punctuation and stop words. To obtain the part-of-speech of the terms, we use Spacy. Once we have the part-of-speech, we select only the nouns, convert them into lemmas, and create bi-grams out of them. With the cleaned data, we feed a Latent Dirichlet allocation (LDA) model provided by Gensim. This model tries to identify the topics given a set of documents. For our specific case, we want to identify topics given in the speeches in the dataset. The number of topics to be created is customizable in the script. With the output of LDA, we made the transformations for t-SNE. We illustrate these steps in Figure 2[E].

3.4. Visualizations

GoViz provides four interactive visualizations: treemap, network, scatter text, and t-SNE. Each visualization has a different level of user interaction that facilitates a more detailed analysis of the numbers and terms present in the visualization. To use all GoViz resources, the user must specify two groups of people's names with the aim of comparing the speeches. If not informed, GoViz still brings the treemap and t-SNE visualizations.

Focusing on understanding the main terms mentioned by speakers, we use a treemap to show the top 20 nouns. If the user specifies the two groups of people's names, GoViz shows the top 20 for each group, using two different colors, as exemplified in Figure 3. Otherwise, it shows the general top-20, as presented in Figure 7. The size of each rectangle represents the frequency of the term. For this specific figure, we omitted words that do not fit the rectangle, as we increased the font size for better visualization.

The treemap allows us to overview the main terms, but it is limited to 20 of them. To provide a deeper analysis, we use the scatter text visualization. To build the scatter text, the user must specify two groups of persons that will have their speeches compared, considering the terms they use. Thus, the visualization shows terms

Fig. 3 – Most frequent nouns in the PCI Covid dataset.

used by one group, by the other, and those used by both. As presented in Figure 4, the terms in the center are used by both sides. On the top-left, we have the most used terms by group 2, while on the bottom-right, we have the most used terms by group 1. This is important to show where the discourse can be similar and at which points they diverge.

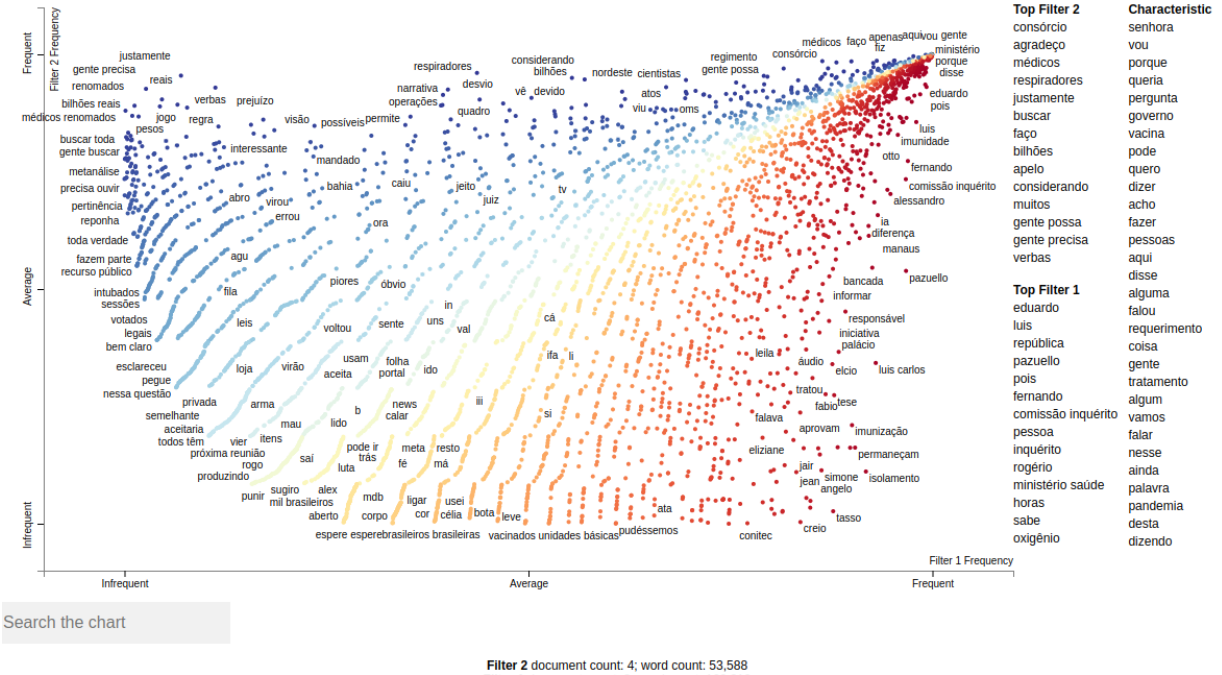

Fig. 4 – Scatter-text visualization with PCI Covid dataset.

To verify which people were cited during the speeches, we used Cytoscape, a network visualization provided by Dash. It shows the relationship between the speaker and the people mentioned. Figure 5 shows an example with the speaker's name in the center and the connections showing how many times he/she mentioned each person.

Finally, the visualization generated by t-SNE (Figure 6) aims to show the relationship between topics and who is talking about them. Each circle represents a speaker, and the size of each circle means how many times that speaker talked about the topic. It is possible to see the speaker's name with a mouse click on the circle or selection. Each color represents a different topic, and their position in the graph means how close each group is to the other. Using t-SNE, we can see a complement from the treemap, where we can focus on each speaker and understand which points they are making during their speech.

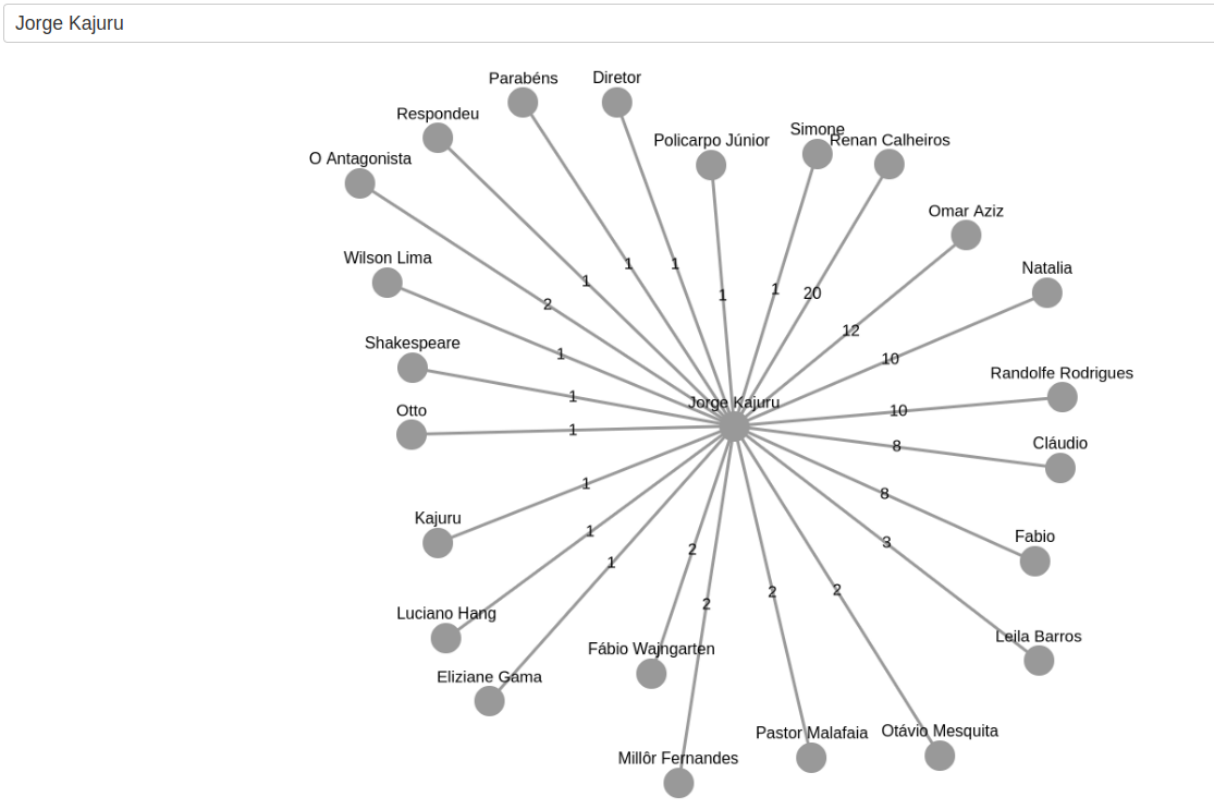

Fig. 5 – Cytoscape visualization with PCI Covid dataset.

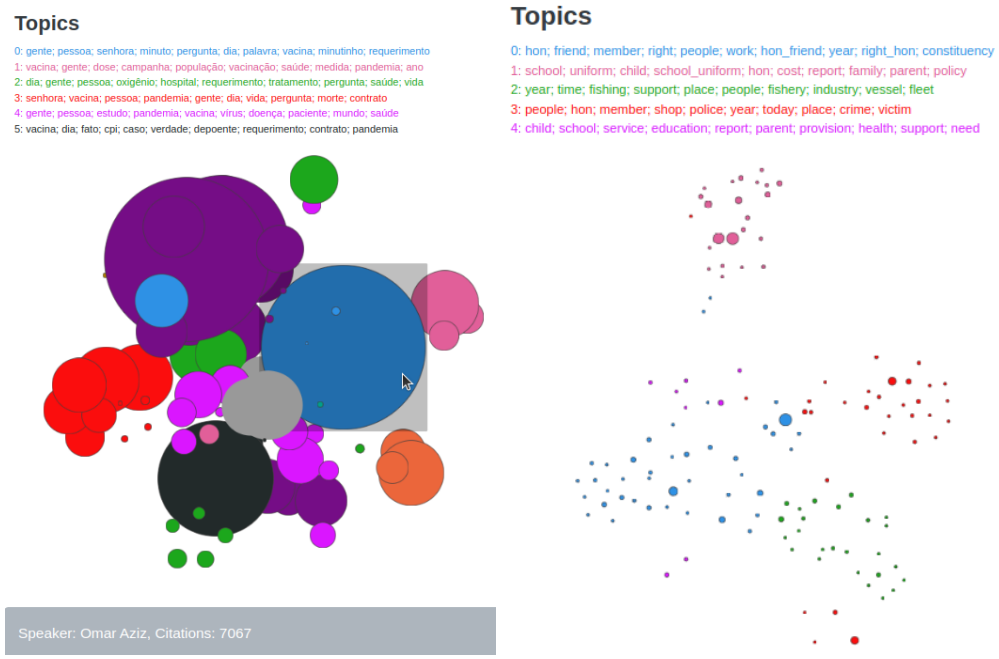
4. Case Studies



This section presents two case studies using different datasets containing government speeches. We evaluate GoViz on its qualitative aspect, considering two datasets, one in Portuguese and the other in English. The dataset in Portuguese describes the Parliamentary Commission of Inquiry (CPI) dataset about the COVID-19 pandemic. On the other hand, the dataset in English is the ParlSpeech V2 (Rauh & Schwalbach, 2020). Our goal is to show how GoViz can bring the main topics into discussion in both datasets. To validate our goal, we read some of the transcriptions and compared them to what GoViz brings as a result.

4.1. Datasets

The dataset in Portuguese contains the transcriptions from every speech made during the Parliamentary Commission of Inquiry (CPI) of the COVID-19 pandemic in Brazil (see Section 4.2). The dataset was originally made publicly available by the Brazilian federal senate. Later, it was treated and made available by *Base dos Dados*[12], a non-governmental, non-profit, and open-source organization. Besides the speech transcriptions, the entire dataset contains information about the speaker (name, genre, and category; political party acronym; federal unity of Brazil; and the parliamentary bloc) and the speech (besides the text, it has the duration, start, and end time). However, our approach uses only the transcription and the speaker name columns. The transcription column contains a total of 735k words.

The English language dataset we tested is the ParlSpeech V2 (Rauh & Schwalbach, 2020) (see Section 4.3). It contains transcriptions from parliamentary speeches from Austria, the Czech Republic, Germany, Denmark, the Netherlands, New Zealand, Spain, Sweden, and the United Kingdom. For our case, we consider only the House of Commons corpus, which contains data from the United Kingdom. This corpus contains information from 1988 to 2019 about the speech's date, speaker, transcription, political party, and agenda topic. However, for our experiments, we only select data from a single day, the 5^{th} of November 2019, which consists of 114k words.

4.2. Case Study 1: Parliamentary Commission of Inquiry

A Parliamentary Commission of Inquiry (PCI) often investigates complaints of irregularities carried out by agencies related to the Brazilian government. In 2021, a PCI was instituted to investigate whether there were any crimes of responsibility, possible omissions, and irregularities during the actions promoted in managing the COVID-19 pandemic in Brazil. The discussion on the PCI focused on adopting treatments without scientific evidence, such as using medications like chloroquine and azithromycin. On the other hand, there were campaigns against vaccination and delays in acquiring vaccines. The non-mandatory use of masks and social distancing was also pointed out.

Before the pandemic, Brazil already suffered from intense political polarization (Juvino Santos et al., 2022). Such polarization is reflected directly in the PCI speeches. To show this polarization, we select two groups of senators: the government's base and the opposition. The Government's base comprises: Ciro Nogueira, Jorginho Mello, Marcos Rogério, and Eduardo Girão. The opposition comprises the senators Omar Aziz, Renan Calheiros, Randolfe Rodrigues, Simone Tebet, Humberto Costa, Eduardo Braga, Otto Alencar, and Tasso Jereissati. We selected these names based on their position during PCI.

The treemap present in Figure 3 shows that for the opposition (blue color), the most frequent terms are: *vacina* (vaccine), *contrato* (contract), *requerimento* (application), and *reunião* (meeting). These terms were expected as PCI investigated if there was any irregularity in the vaccine acquisition.

In scatter text visualization (Figure 4), we can see that the opposition uses terms such as "isolation", "immunization", and "accountability" more frequently. From the Government's base, we can see a more financial appeal, with terms such as "funds", "damage", and "public resources". Moreover, the issue of vaccines has been hotly debated on both sides.

In this PCI, there was an effort to define the people responsible for the potential negligence during the pandemic. The network visualization generated by Cytoscape shows the relation between the deponent and the people they mentioned in their speech. In Figure 5, we selected Jorge Kajuro, a Senator who spoke in PCI. His name is in the center of the image. Names cited by Jorge, such as Natalia and Fabio, are from people invited to depose. Fabio, for example, is a former Secretary of Communication of the federal government and has been investigated for possible irregularities. We can also see that names such as Omar Aziz appear multiple times,

as he was the president of this PCI.

Figure 6 shows the main terms of the PCI, grouped by topics of interest. For this visualization, we selected 14 topics. In the figure, we limited the number of topics to six to improve visualization. As we can see, the term *vacina* (vaccine) appears as a topic multiple times because they can be interpreted in different scenarios, such as in a more administrative way in topic 2, or focusing on health in topic 3. Considering the PCI scenario and the identified topics, one can understand that the main focus was on investigating contractual points on vaccine acquisitions (topic 2) and conducting treatments and hospital supplies (topics 3 and 4).

4.3. Case Study 2: House of Commons corpus

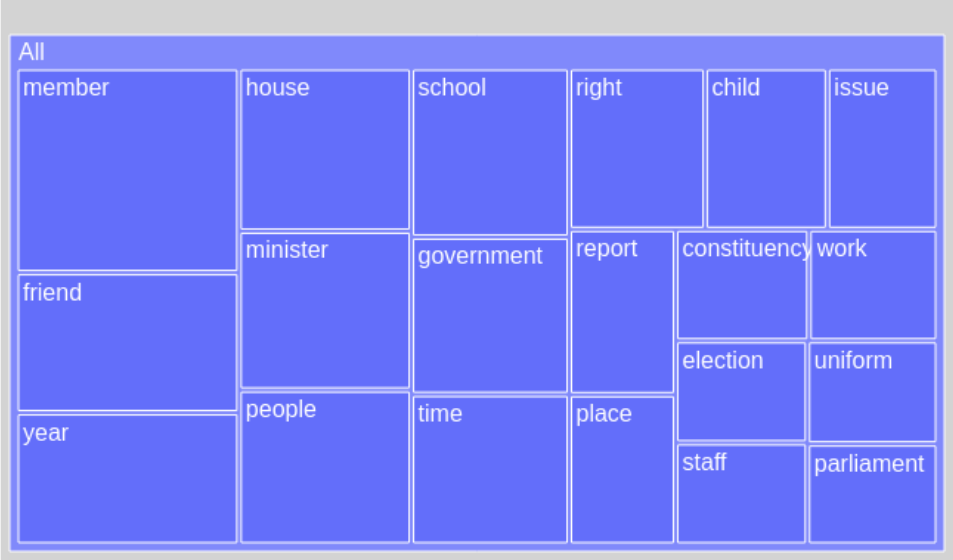

Fig. 7 – Most frequent nouns in House of Commons (ParlSpeech dataset).

Our focus in analyzing the House of Commons corpus was testing whether we could also use GoViz in English documents. The dataset contains information ranging from 1988 to 2019. On this day, the agenda had more than 20 topics involving UK international relations, Human Rights, Climate Change, among others. Thus, considering this scenario without previous knowledge about these topics, we show the most used nouns, without defined groups, in Figure 7. Given the diversified agenda of the day, most terms are more generic. Yet, we can see that some of them indicate the human rights topic as being more frequent, such as 'house', 'right', and 'child'. Figure 6(a) shows the t-SNE visualization for the same day. We can see that the automatically selected topics involve Human Rights and Health (topics 1 and 4), while topic 2 focuses more on the industry. Similar to Figure 6(b), each point in the figure represents a person. The point size indicates the number of times the person mentioned something about the topic (color).

5. Discussion

GoViz is a web-based application that does not require programming skills to use. The main contribution of this work is that it allows extracting information from texts in English or Portuguese without the need to read large amounts of data. With such a feature, GoViz can potentially increase citizens' participation in parliamentary issues. The increase in participation is a consequence of the simplified access to information. In general, our tool brings more interesting results when users provide polarized groups, as shown in Section 4.2. As demonstrated in Section 4, we still obtain an overview of the information presented in the final PCI report without previously knowing the dataset.

Since GoViz is a generic tool capable of handling different datasets, some details were left out. For example, Spacy has excellent accuracy in the named entity recognition task. However, it is not perfect. If we look

carefully at Figure 5, we will see terms, such as *respondeu* (replied), *parabéns* (congratulations), and *diretor* (director) that are not person names. Spacy allows customization, but we did not customize it as we expect GoViz to manipulate any dataset, and it should be as generic as possible to deal with a diverse range of topics. We noticed that different names sometimes call the same person throughout the speech. This occurs when the person has a compound name, or the family name is not considered. Jair Messias Bolsonaro (Brazilian president at the time of the PCI) is a good example as he is mentioned throughout the process as *Jair Bolsonaro*, *Jair Messias Bolsonaro*, or just *Bolsonaro*. Although we consider *Jair Bolsonaro* and *Jair Messias Bolsonaro* as the same person when we only have "Bolsonaro", it can also be referring to one of their sons. This makes it almost impossible to guarantee that we always correctly detect all persons' names.

In future work, we aim to incorporate modern models such as Large Language Models and explore sentence representations like Sentence-BERT (Reimers & Gurevych, 2019) to preserve semantic relationships and better capture deep connections within the discourses. Furthermore, to validate GoViz, we aim to conduct user testing to collect feedback and provide design improvements. Other improvements include a new version of GoViz that works entirely online and supports other languages, such as Spanish and French. Finally, we aim to include arc diagrams to improve visualizations and show the correlation among people's dialogues.

6. Conclusion

In this work, we introduce GoViz, a visualization tool that automatically extracts and summarizes speech information. We propose a pipeline that extracts part-of-speech, named-entities, among other information, to provide visualizations that show who the main speakers are, how they connect, and the subject of the speeches. The user can improve GoViz output by adding specific information to the tool, such as person names that belong to two different groups. In this case, GoViz generates visualizations that compare the two groups according to the most spoken terms and connections between them. We evaluate GoViz in both Portuguese and English using open data from the Brazilian government and the United Kingdom. As a result, we show that the generated visualizations can provide insights about the main topics in discussion, as well as the main actors. This is an advance compared to existing tools, which require user input and previous knowledge to work properly.

Submitted: 31 January 2025, Revised: 26 March 2025, Accepted: 21 April 2025, Published: 19 May 2025

Abstract. Legislative public spaces are important structures for participatory democracy, allowing citizens' voices to get engaged with politic decisions. As a consequence of the popularization of information and communication technologies, internet based tools have played an important role to improve public participation in political decisions, known as e-Democracy. These tools are usually composed of a set of functionalities or small services, named microservices. The better the microservices, the higher the citizen participation. This work investigates how to extract useful knowledge from citizen participation in the microservices of the public portal of the Brazilian Chamber of Deputies. For such, it analyzes public comments incorporating Natural Language Processing and Artificial Intelligence techniques in a platform named Ulysses. The tasks developed on this paper focus on a temporal analysis of comments on bills in the portal through Stance Detection and dynamic Topic Modeling tasks. For the first task, OxêSD, a BERTimbau-based model, was trained on two different corpora, one of them translated into Portuguese, and its predictive performance was evaluated using the F1 and ROC-AUC metrics, achieving 73% for both on our proposed Political-BRSD a mixed dataset containing both translated content from a bigger multilingual dataset (adapted from x-Stance) and bill-specific content (adapted from Ulysses-SD); for the second, BERTopic, a Topic Modeling framework, was used. Visualization tools to analyze how the proposed approach addressed the task were also used to explore the knowledge extracted. They allow the user to understand over time how the comments relate to each other and how the comments relate to a given legislative bill.

Keywords. Natural Language Processing, Legal Text Analysis, Stance Detection, Topic Modeling.

1. Introduction

Public portals, defined as inclusive and deliberative instances not monopolized by any entity, play a crucial role in democracies (Addor, 2018). As societies strengthen their relationships with the state, citizens evolve from passive to active participants, engaging in public discourse and decision-making processes. This evolution prompts a continuous redefinition of public spaces and democracy itself (Cardoso, 2007). Participatory

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

democracy, often viewed as a combination of direct and indirect democracy, has undergone a contemporary reevaluation. It now encompasses universal participation, leveraging various tools to expand public spaces in political and public decision making (Macedo, 2008). However, universal participation raises concerns about potentially suppressing the voices of minorities, necessitating careful attention to the expression of diverse social groups (Lessa, 2010).

The advent of the internet and digital technologies has transformed interactions among citizens, politicians, and governmental institutions. This transformation has given rise to the concept of e-Democracy, wherein Information and Communications Technologies (ICTs) support democratic decision-making, enhancing both institutions and processes (Pereira et al., 2022). Early studies emphasized the need to analyze the quality of information and interactions on the internet, focusing on their relevance, scope, and consequences (Rothberg, 2008). This paper focus on e-Democracy, exploring how ICTs can improve democratic processes. E-democracy operates on three dimensions: establishing essential conditions for the use of information and communication technology (ICT) in government, emphasizing citizen participation (e-participation) in decision-making, and concentrating on the effective delivery of government services online (e-Government) (Kneuer, 2016; Ronchi, 2019).

Natural Language Processing (NLP), a subfield of Artificial Intelligence, has evolved in recent years. Fueled by increased computing power, abundant data, and advances in Machine Learning, NLP encompasses various tasks, including Word Processing, Information Retrieval, and Sentiment Analysis (Chowdhary, 2020; Hirschberg & Manning, 2015). Stance Detection, a subtask of sentiment analysis, involves categorizing the expressed position of a given text regarding a particular target. This classification task finds applications in diverse areas such as rumor stance classification and fake news detection (Kuçuk & Can, 2020). Another important NLP task is Topic Modeling, an unsupervised technique for extracting latent topics from textual data. It plays a significant role in uncovering the underlying themes within complex and large corpora across various domains (George & Birla, 2018; Yamunathangam et al., 2021). Therefore, considering the temporal dynamics of language use, Temporal Text Analysis allows understanding how discourses change over time. In the context of media storms, where a specific subject experiences a surge in news coverage within a short time on social media, temporal text analysis becomes relevant (Lukito et al., 2019).

Legal AI and Legal NLP have emerged as areas focused on augmenting, assisting, or potentially replacing legal actors in various tasks. These tasks include the analysis of legal documents, like laws, bills, legislation texts, case laws, and more, often scattered across different databases and formats (Avgerinos Loutsaris et al., 2021; Katz et al., 2023). In this context, the Brazilian Chamber of Deputies uses multiple NLP and AI tools in a platform named Ulysses Câmara dos Deputados, 2018, which processes legislative texts from its portal named *E-democracia*[1]. The goal of this research is to apply NLP methods in the temporal domain to analyze comments on bills written on the E-Democracia portal through the Ulysses platform in order to understand how public opinion towards a given subject evolves through the time. In this work, we (1) provide a deep and thorough review of textual analysis within the legal domain over time, emphasizing Stance Detection and Topic Modeling tasks; (2) present significant advances in the PT-BR Stance Detection task within the legal domain by introducing a new large corpus (Political-BRSD[2]) and a novel Stance Detection model (OxêSD[3]); and (3) through Stance Detection and Topic Modeling over time, develop tools that enable an understanding of how texts engage with a specific bill and with each other over time.

2. Related Work

In this section, we introduce related works in NLP, specifically in Stance Detection and Topic Modeling, considering Legal Domain and Temporal applications.

2.1. Legal Domain Applications

Avgerinos Loutsaris et al., 2021 address the challenge posed by the enormous volume of legal information in each European Union country due to the integration of Digital Governance across all levels of society. They

[1] Available in https://www.camara.leg.br/participe
[2] Available in https://huggingface.co/datasets/cerqueiramatheus/Political-BRSD
[3] Available in https://huggingface.co/cerqueiramatheus/OxeSD

have developed an open and automated legal system that handles various tasks, including information extraction (such as law title, number, number of pages, and creation date), Named Entity Recognition (NER), law decomposition, and opinion extraction. On a different note, Ikram and Chakir, 2019 highlight the difficulty of archiving legal documents and accessing relevant information in Morocco. To assist legal professionals, they propose text classification methods employing multiple Machine Learning (ML) induced models. In the context of the Portuguese language, there are also several studies that deal with different legal text analysis problems. Carvalho and Barbosa, 2018 implement a legal visualization based software using tokenization, tagging, and lemmatization to enhance the understanding and analysis of documents such as the Portuguese Constitution. The Lima et al., 2021 study focuses on comparing different feature extraction models in Brazilian Portuguese texts from the Tribunal de Justiça do Rio Grande do Norte (TJRN), a clustering technique that can be useful for lawyers and even to finding controversial issues in legal texts. Also in Brazilian Portuguese, Medina et al., 2022 propose a model with different tasks, such as summarization, feature extraction, and classification, focused on legal proceedings texts.

Nababan et al., 2022 study is focused on understanding public positions and sentiments about the Job Creation Bill in Indonesia, through a Twitter data analysis; they collected and annotated several tweets to create a new corpus and also conducted experiments with different ML algorithms, such as Naïve Bayes, Support Vector Machine, and Logistic Regression. These algorithms were chosen because of their different inductive biases. Bergam et al., 2022 work delves into the analysis of US Supreme Court documents through Stance Detection, introducing and comparing new metrics that allowed them to correlate the responsiveness to public opinion to ideology expression. They also proposed *SC-stance*, a new dataset focused on legal Stance Detection, matching written opinions to legal questions. Usually, studies adopt a multilingual approach. Lai, Cignarella, et al., 2020 work select topics about politics in multiple languages, investigate the portability of tools, and then evaluate MultiTACOS algorithm performance. Egli et al., 2023 proposal is centered on the analysis of official voter information booklets; their experiments achieved best results using a fine-tuned multilingual BERT model Devlin et al., 2019. Finally, within the Brazilian Chamber of Deputies context, Maia et al., 2022 use digital media comments on political bills to understand the stances of the citizens and group the polarity of public opinions about new discussion topics. To achieve this, they developed a new dataset, *Ulysses-SD* and implemented a mBERT model. It is the nearest application in domain and approach compared to our goal; however, none of them leverages the temporal information.

Sarne et al., 2019 work is focused in large-scale corpora of privacy policies using unsupervised learning techniques. They developed a framework for privacy policy Topic Modeling and applied it over a corpus of privacy policies of mobile applications crawled from the Google Play Store. To build their framework, they used GraphLab, a machine learning platform that supports Latent Dirichlet allocation (LDA) Blei et al., 2003 Topic Modeling. Similarly, LawNet-Viz is a web-based system developed by La Cava et al., 2022 for modeling, analyzing and visualizing law reference networks extracted from law corpus. Their work was demonstrated using the Italian Civil Code and implemented the LDA topic model Blei et al., 2003 available on the Gensim Python library for the language modeling process. LawNet-Viz can benefit since lawyers and jurists to citizens. Joshi and Saha, 2020 developed a framework to automatically extract knowledge from Code of Federal Regulations from the United States government, such as key terms, rules, relationships and topic summaries. They used the Gensim library and the LDA Blei et al., 2003 topic model for the extraction of topic from summarized subsections task. Their work automated the analysis from CFR regulations. For the Brazilian Portuguese context, Silva et al., 2021 designed a specific sentence embedding technique to build topic models and achieved good results compared to other multilingual sentence embedding techniques. Their approach applied BERTopic Grootendorst, 2022 to extract topics from political comments on Brazilian bills and produced three different datasets. Again, on the same domain, the temporal information was not explored, one of our main goals in this work.

2.2. Temporal Applications

Usually, the temporal applications are focused in time information extraction. Viani et al., 2020 developed a system to identify relevant electronic health records and extract time expressions from them; this system was applied to two electronic health records datasets and resulted in the creation of a new corpus annotated with normalized values for time expressions. However, within the context of this work, our main task is to understand how texts can be grouped over time, that is, the analysis of documents in document networks Zhang and Lauw, 2022, specifically with Stance Detection and Topic Modeling. Although there are multiple

applications using temporal information, our work differs by combining two tasks, Stance Detection and Topic Modeling, for understanding texts in the legal domain.

Alturayeif et al., 2023 review highlighted that, despite that opinions change through time and the importance to record and evaluate temporal data, diachronic evolution is not a common explored topic within Stance Detection field; it also presented three different studies. The first, from Lai et al., 2019, introduces how political debate can be understood in a diachronic perspective, focusing on the aggregation of empirical data in a given granularity (days, weeks, months). Their main goal was the analysis of the Twitter debate about the 2016 referendum of Italian Constitution; they developed a new corpus leveraging the diachronic perspective to understand the citizens' opinion evolution through time. The second, proposed by Lai, Patti, et al., 2020, introduces a novel approach and annotation schema for Stance Detection to investigate the impact of social network community features and the evolution of stance over time within the Brexit referendum context. Their analysis highlighted the importance of temporal features. Finally, Alkhalifa et al., 2021 work produced two large-scale stance datasets using temporal information to mitigate the performance deterioration of classifiers over time, that is, to reduce impacts of the temporal gap between training and test data. Their approach adapted word embeddings used in training of the stance classifier.

One of the earliest approaches to dealing with the Topic Modeling task over time was proposed by Blei and Lafferty, 2006. Their work developed the Dynamic Topic Models, that employed probabilistic time series models has been developed to analyze the temporal evolution of topics within extensive document collections. Since then, several different proposals have been developed. He et al., 2014 emphasize the increasing interest in this area and mention, beyond the Dynamic Topic Models, its newer variations, like continuous-time and online multi-scale proposals. Their work also proposes a new method joining sentiment and topic model over time. Sharma et al., 2022 applied dynamic Topic Modeling on vaccine-related discussions on Twitter from 2020 to 2021, aiming to track public perception of vaccines over time and identify the factors influencing these evolving opinions. Ghosh et al., 2017 study explores the use of supervised temporal topic models to analyze large corpora of news articles and identify trends; they evaluated their method through multiple infectious disease outbreaks data from the United States of America, China and India. Finally, Grootendorst, 2022 study proposes BERTopic, a Topic Modeling framework that implements dynamic Topic Modeling.

3. Method

In this section, we describe our method, focusing on the steps, input and output of our task, the models used, and the evaluation metrics. Briefly, our approach follows the presented on Figure 1.

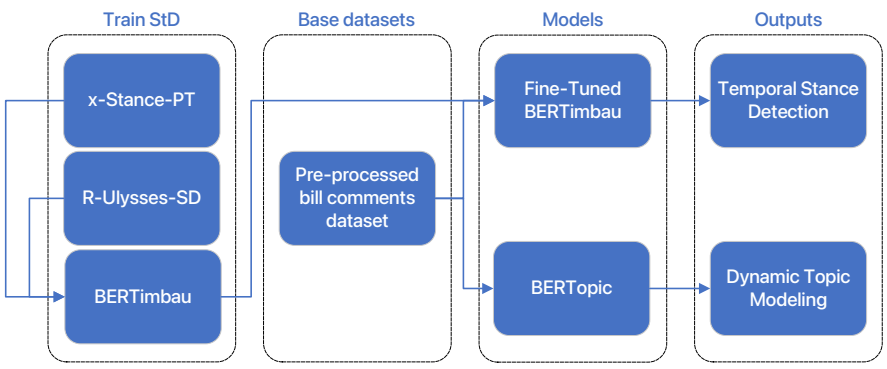

Fig. 1 – Methodological approach

3.1. Comment Analysis

Our main task is focused on the temporal analysis of Brazilian political comments through Stance Detection and Topic Modeling. First, we fine-tuned a model for the Stance Detection task using two different datasets

(train datasets). For the main task, our input is composed by comments written about a given bill on the E-Democracia portal (base datasets). We employ a pre-processing step for the base datasets. Then, we execute models for Stance Detection and Topic Modeling given the comments, what will be discussed in the next section. Finally, we provide graphs containing the output of each task (polarities over time and topics) for the given comments set.

3.2. Models

First, for the Stance Detection task, we fine-tuned a pre-trained BERT model, specifically BERTimbau. BERT models employ a bidirectional context approach, creating representations of words considering their contexts within a given sentence. BERTimbau, specialized for Brazilian Portuguese, outperforms generic BERT on Portuguese tasks. For the temporal Topic Modeling task, we utilized BERTopic (Grootendorst, 2022), a model leveraging class-based TF-IDF with pre-trained S-BERT models (Reimers & Gurevych, 2019) containing multiple Topic Modeling approaches, including Dynamic Topic Modeling.

3.3. Evaluation Metrics

To assess the performance of our models, we used the Hugging Face Evaluate library (HuggingFace, 2023), leveraging both the weighted F1 Score and Receiver Operating Characteristic Area Under the Curve (ROC AUC) metrics. The weighted F1 score is the harmonic mean of precision and recall, computed for each class independently and then averaged, with the contribution of each class weighted by its prevalence in the dataset. Simultaneously, the ROC AUC metric was employed to evaluate the model ability to discriminate between positive and negative instances, offering insights into their overall predictive power.

4. Experimental Setup

In this section, we describe our base dataset used as input of the tasks, the datasets used to training the Stance Detection Model, its setup and implementation.

4.1. Base Datasets

To generate the outputs for the Stance Detection and Topic Modeling tasks, we extract comments associated with specific bills from the E-democracia portal, each producing a unique dataset. Similarly to the works of (Maia et al., 2022; Silva et al., 2021), our extracted datasets are composed by comments written in Brazilian Portuguese from CSV files, containing columns such as comment ID, author, timestamp, number of likes, and manual labels. Finally, we preprocess the comments, filtering for a minimum length (default set at 15 characters) in order to keep only real comments and produce better results.

4.2. Train Datasets

Given the lack of large datasets for Brazilian Portuguese Stance Detection, we adopted a combination of the x-Stance dataset (Vamvas & Sennrich, 2020) and the Ulysses-SD dataset (Maia et al., 2022). To address language disparities, we translated the x-Stance dataset to Portuguese using the Google Translator class from the Deep Translator package (Baccouri, 2023), resulting in the x-Stance-PT dataset[4]. We also reduced the Ulysses-SD to two classes (`FAVOR` and `AGAINST`) in R-Ulysses-SD[5]. The Political-BRSD dataset, a combination of x-Stance-PT and R-Ulysses-SD, was created to join information from both datasets, as illustrated in Table 1. Each of them followed a 70/15/15 division for train, test and validation.

4.3. Setup and Implementation

Our Stance Detection experiments consisted in four approaches trained on a NVIDIA Tesla P100 GPU with 16GB memory, employing the same hyperparameters (`learning_rate` = 2^{-5} and `epochs` = 4). The approaches

[4]Available in https://huggingface.co/datasets/cerqueiramatheus/x-Stance-PT
[5]Available in https://huggingface.co/datasets/cerqueiramatheus/reduced-Ulysses-SD

Tab. 1 – **Number of comments for the train datasets** – Number of comments in each label for the R-Ulysses-SD, x-Stance-PT and Political-BRSD datasets.

Dataset	Favor	Against	Total
R-Ulysses-SD	524	685	1209
x-Stance-PT	34001	33270	67271
Political-BRSD	34525	33955	68480

included models fine-tuned only on Ulysses-SD, only on x-Stance-PT, sequentially on x-Stance-PT and Ulysses-SD, and finally on the merged Political-BRSD dataset. Each model received as input a combination of topic information, the comment itself from each dataset and a given label (`FAVOR` or `AGAINST`). For temporal Topic Modeling, we used Dynamic Topic Modeling within the existing BERTopic implementation on Ulysses services, which automatically selects 10 topics, automatically named.

5. Results

To exemplify our results, we selected two different bills from the E-democracy portal to show the outputs of each task. We selected the following bills because they have a high number of comments and are recent, both created in 2020: 1) Public Administration – **PL 2630/2020** (Câmara dos Deputados, 2020) (to combat fake news); and Health – **PL 2564/2020** (Câmara dos Deputados, 2021) (to establish salary floor for nursing professionals).

5.1. Stance Detection Model Training

Tab. 2 – **F1 and AUC measures** – F1 and AUC measure results for the proposed models 1, 2, 3 and 4 on x-Stance-PT, R-Ulysses-SD and Political-BRSD datasets.

Dataset	Model							
	1		2		3		4 (best)	
	F1	AUC	F1	AUC	F1	AUC	F1	AUC
x-Stance-PT	0.40	0.51	0.71	0.71	0.58	0.61	**0.73**	**0.72**
R-Ulysses-SD	0.86	0.85	0.54	0.56	**0.87**	**0.86**	0.85	0.84
Political-BRSD	0.58	0.61	0.71	0.71	0.59	0.62	**0.73**	**0.73**

We follow the model names from the previous section: 1) BERTimbau trained on R-Ulysses-SD; 2) BERTimbau trained on x-Stance-PT; 3) BERTimbau trained on R-Ulysses-SD and then on x-Stance-PT; and 4) BERTimbau trained on Political-BRSD. As Table 2 shows, 1 and 2, as expected, produced the worst outputs; they specialized only on the context of the dataset that they were trained. Model 3 appears to be forgetting its first training on x-Stance-PT, but this is a known issue since the recommended number of epochs for this task, at maximum, 4 (Devlin et al., 2019) and we performed two training steps of 4 epochs each. Finally, model 4 produces the best results, leveraging both datasets.

Our best model, BERTimbau trained on Political-BRSD, outperforms results from the original x-Stance work (F1=0.69). To the best of our knowledge, our produced results are the best for cross-topic Stance Detection in the PT-BR political domain. Then, we evaluated its confusion matrix produced for the test datasets. For R-Ulysses-SD, its performance is better at class `AGAINST`, with the same number of false negatives and false positives. However, for x-Stance-PT and Political-BRSD, the model produces better results for the `FAVOR` class; the number of false positives and false negatives is still similar. This indicates that our model learned to better classify the `FAVOR` stances, even with the use of well-balanced data sets, as previously shown.

5.2. Tasks Outputs

Usually, the number of comments on the bills is not constant, and there are months with much more interaction and this is due to external factors, like news or social networks; some bills are also more controversial than others. However, these factors are not explored in this work, as we propose a first step to this analysis, focused on identifying the reactions and interactions within the comments of a given bill.

5.2.1. Stance Detection

As shown in Figure 2, there is a prevalence of the `FAVOR` class for the PL 2630/2020, increasing from December 2021 to January 2022, what indicates that the bill is probably less controversial; its purpose (salary floor for nursing professional) can be a reason to it. However, PL 2564/2020 (Figure 3) seems to be more controversial, with small peaks before 2023 and two huge peaks between April 2023 to June 2023. Despite its majority class is `AGAINST`, there is a significant number of `FAVOR` comments.

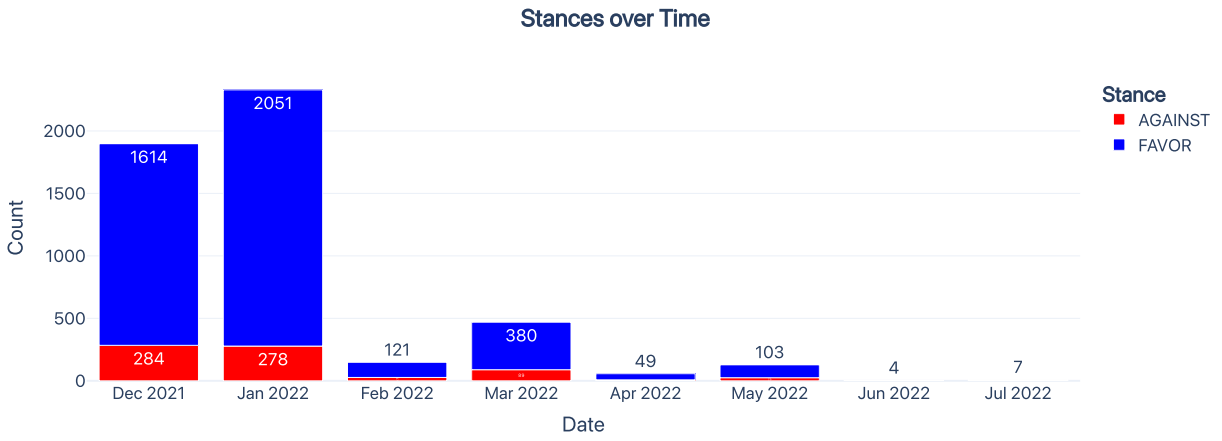

Fig. 2 – Stance Detection output for PL 2630/2020

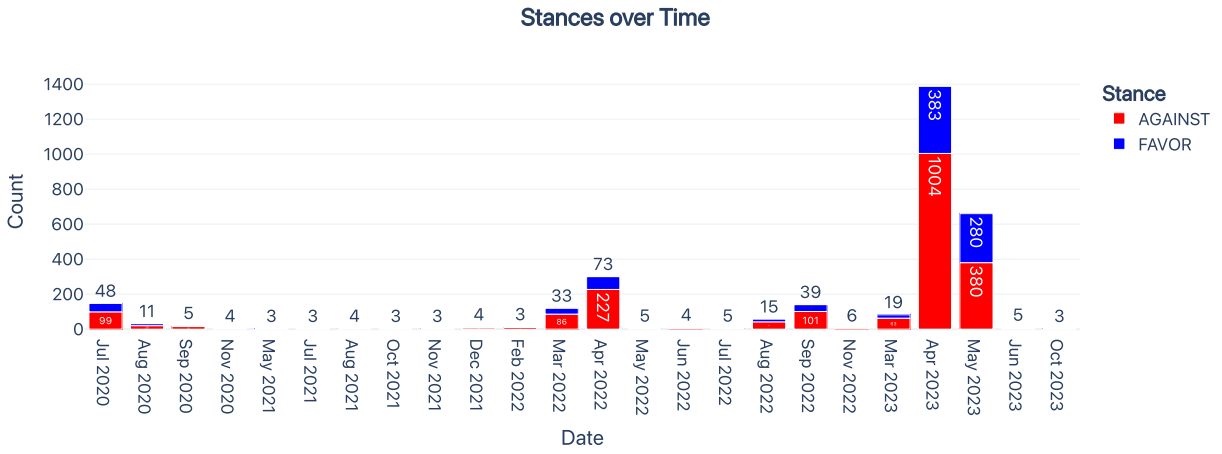

Fig. 3 – Stance Detection output for PL 2564/2020

In our experiments with multiple bills, there was a prevalence of comments distribution over time on bills with this same behavior, that is, concentrated in two or three months, with isolated peaks over time.

5.2.2. Topic Modeling

Figure 4 shows the comment groups for PL 2630/2020, matching the frequency peaks from the Stance Detection task. Topic 0 (PT-BR: `paciente_respeito_aprovar_trabalho`, EN-US: `patient_respect_approve_work`) groups most of the comments. For PL 2564/2020, as PL 2564/2020, there is again a concentration in a single topic, with other minor topics. Topic 0 (PT-BR: `rede_informação_fake_internet`, EN-US: `network_information_fake_internet`), as shown in Figure 5, groups most of the comments over time.

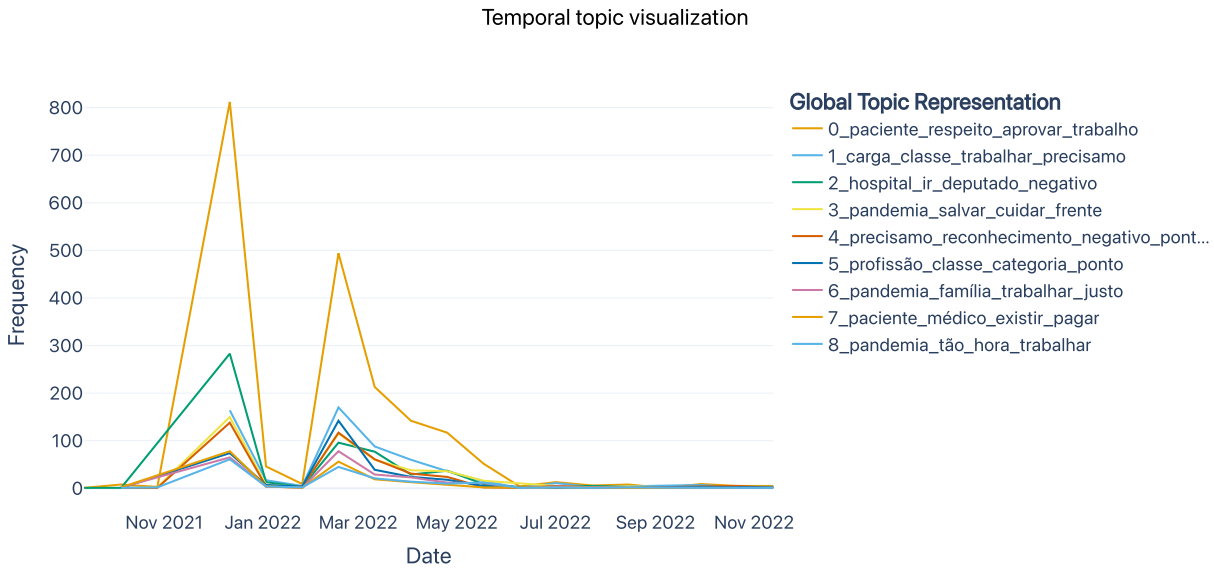

Fig. 4 – Topic Modeling output for PL 2630/2020

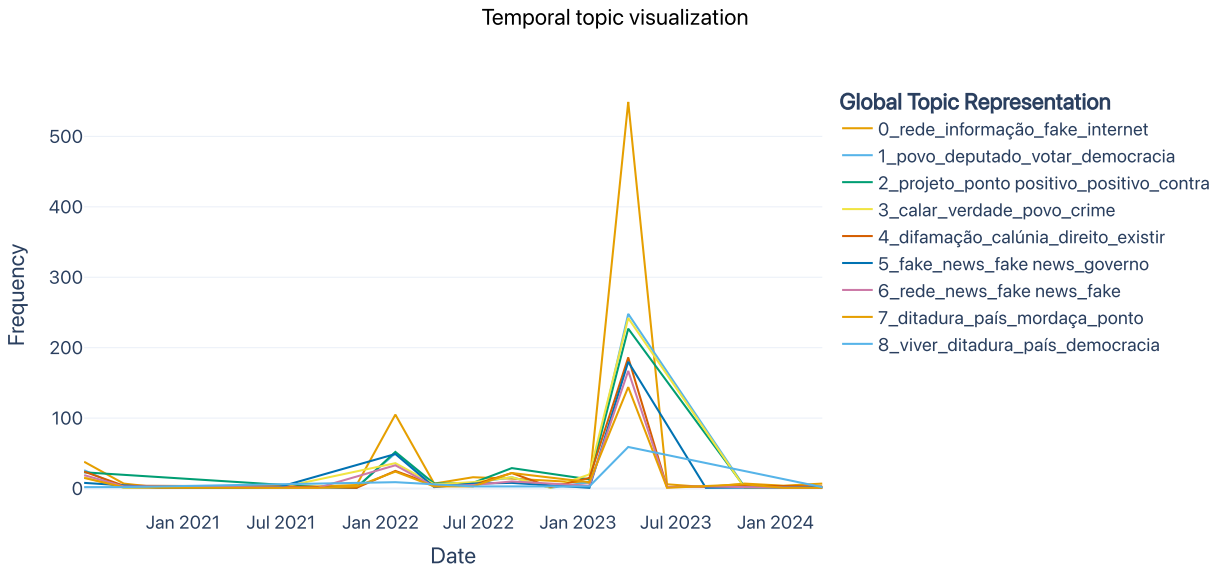

Fig. 5 – Topic Modeling output for PL 2564/2020

With multiple bills, there was always a main topic, as in the previous examples. As all the comments are about the same bill, this is expected behavior. However, the other topics seem to be relevant and can reveal important insights.

5.3. Discussion

Even though the Stance Detection and Topic Modeling tasks have been designed to be globally available, that is, to work on all available bills, their performance depends on the comments distribution over time (as shown in the first example), the total amount of available comments (usually bills take months to have a few comments), external factors (as the influence of external discussion and the bill relevance). Our selected examples were manually picked, since the Brazilian Chamber of Deputies services do not provide filters to select the most commented bills in a complete period, only in the last six months. In the examples, the Stance Detection visualization provides good insights about citizens' responses to bills; although the Topic Modeling focuses

on one topic, it groups other relevant secondary topics, which can be better seen through dynamic filtering in the graphs, which are interactive.

5.4. Limitations

Due to the lack of well-established evaluation metrics for dynamic topic models, we were unable to quantitatively assess the performance of our proposed model. However, we acknowledge the recent work of (James et al., 2023), that proposed a novel evaluation measure for dynamic topic models that analyzes the changes in the quality of each topic over time; they propose Temporal Topic Coherence, Temporal Topic Smoothness, Temporal Topic Quality and Dynamic Topic Quality. It is important to note that the non-temporal evaluation, that is, the traditional Topic Modeling evaluation, is already developed by other projects within Ulysses services, which is beyond the scope of this work.

Although significant progress has been made in developing cross-topic Stance Detection models, the evaluation of their performance remains a challenge. As highlighted in (Reuver et al., 2021), the generalizability of cross-topic Stance Detection models across diverse topics and socio-cultural contexts is a critical aspect that requires further investigation and demonstrates that topic, class, and their interaction can significantly impact model performance. This underscores the need for continuous evaluation of cross-topic Stance Detection models across a wide range of contexts and topics over different datasets to ensure their robustness and generalizability. Our research was limited to the context of Political-BRSD.

6. Conclusions

Our best-performing Stance Detection model (OxêSD, a BERTimbau-based model fine-tuned on Political-BRSD) surpassed results from existing works, demonstrating the effectiveness of our approach in cross-topic scenarios. The dynamic Topic Modeling framework provided a detailed temporal analysis, contributing to a deeper understanding of the evolving discourse around legislative proposals. Despite promising results, our research has limitations. The lack of well-established evaluation metrics for dynamic topic models poses challenges in quantitatively assessing their performance. Future work could focus on refining evaluation measures for temporal analysis tasks. Furthermore, expanding the scope to include more diverse topics and datasets would enhance the generalizability of our models. In this work, we addressed the challenges of cross-topic Stance Detection and dynamic Topic Modeling in the context of Brazilian political discussions. Our experiments with Stance Detection models revealed that training on a combination of datasets (Political-BRSD) significantly improves performance compared to models trained on individual datasets (x-Stance-PT and R-Ulysses-SD). The best performing model (trained on Political-BRSD) achieved superior F1 and ROC AUC scores, showcasing its effectiveness in capturing cross-topic stances in the PT-BR political domain.

The temporal analysis of stance over time provided valuable insights into citizens' responses to specific bills. By visualizing stances and topics, we observed patterns of interaction and identified potentially controversial bills. Our dynamic Topic Modeling framework successfully captured the evolution of topics over time, offering a nuanced understanding of the discussions surrounding legislative proposals. In conclusion, our research contributes to advancing the field of cross-topic Stance Detection and temporal analysis in the context of political discussions. The combination of effective models, dynamic visualizations, and an interactive demo platform positions our work as a valuable resource for researchers, policymakers, and the public interested in understanding and analyzing political discourse.

7. Acknowledgements

We sincerely appreciate the support provided by the research funding agencies CAPES, FAPESP, and CNPq, whose contributions have been essential to the development of this work. Furthermore, we extend our gratitude to the Brazilian Chamber of Deputies, the Center for Applied Research in Artificial Intelligence Recreating Environments (CPA IARA), and the Brazilian National Institute of Artificial Intelligence (IAIA) for their significant support in advancing this research.

Track 5: Digital Government and Sustainable Development Goals

Track Description

The United Nations' Sustainable Development Goals (SDG) are shaping the global agenda in multiple areas, including public opinion, policy, and research. The 17 SDGs, detailed in 169 targets, have an ambition of linking separate goals of sustainable development across different areas, into a unitary vision. The main consequence of this new vision has been to move the focus beyond the individual instances of e.g., environmental impacts of human activities, or economic inequalities, and to link them in a coherent system within the framework of the Agenda for the Sustainable Development 2030. Digital government can act as an enabler to sustainability, equity, and social inclusion and it represents a cross-cutting objective across several SDGs at both sectoral and horizontal level, with a crucial importance in particular for goal 16 which aims to Promote peaceful and inclusive societies for sustainable development, provide access to justice for all and build effective, accountable and inclusive institutions at all levels. This track aimed to gather contributions focusing on the potential benefits and challenges of digital government in supporting the achievement of SDGs and the role of digital technologies in sustaining policy developments at both horizontal and sectoral levels, including, in particular, the impact on democratic innovation and institutional reforms of governance systems.

Submitted: 31 January 2025, Revised: 26 March 2025, Accepted: 21 April 2025, Published: 23 May 2025

Abstract.=Forest lands in India are under severe pressure from illegal encroachment despite the enactment of the Indian Forest Act(IFA) 1927 and Forest (Conservation) Act (FCA) 1980. This situation effectively reduces the land available for afforestation, affecting India's global commitment to fighting climate change. Encroachment in remote locations goes undetected, preventing any measures for removal. The feasibility of applying Artificial intelligence(AI) methods on Very High Resolution(VHR) satellite imagery to automate the identification of encroachments was examined. The evaluation found that the current level of research makes it feasible. A novel method for detection and monitoring of eviction of encroachment on forestland was proposed to increase the land available for afforestation. This method can ensure more CO_2 sequestration to help India meet its commitments in fighting climate change.

Keywords.=Forest, Conservation, Artificial intelligence, Climate change, Encroachment
Research paper, DOI: https://doi.org/10.59490/dgo.2025.1028

1. Introduction

How the current generation deals with climate change will impact all the generations to come. Thanks to the awareness raised in this regard in the last few decades, the severity of the consequences of climate change and the required mitigation efforts is well known. Yet, in 2021, the world faced the calamitous impacts of climate change ranging from the deaths of countless mussels on beaches of Vancouver (Roxanne Egan-Elliott, 2021) to the unprecedented destructive rainfall in China (Jeff Masters, 2021).

1.1. India's global commitment

India's Intended Nationally Determined Contribution (INDC) in response to COP decisions 1/CP.19 and 1/CP.20 for the period 2021 to 2030 consisted of eight decisions which included one related to afforestation (Government of India, 2022). Through afforestation, the creation of an additional carbon sink of 2.5-3 billion tonnes of CO_2 equivalent by 2030 is one of India's INDC (Government of India, 2022).

1.2. Concerns on impact of forest land encroachment in fighting climate change in 2016

Due to the increase in people's concern, questions are rising on the efficacy of the climate change mitigation measures, like afforestation on forest land. In the Lok Sabha of the Indian Parliament, such a question was raised in July 2016 by the Member of Parliament Neelam Sonker (Sonker, 2016). Amongst others, the most pertinent question was,

> Will the Minister of Environment, Forest and Climate Change be pleased to state :(a) whether it is a fact that rapid climate change has been taking place in the country due to encroachment on forestland;

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

(Sonker, 2016). However, the reply to this question stated that

> No study has so far come to the notice of the Ministry regarding rapid climate change in the country due to encroachment on forest land.

, the subsequent questions raised by Neelam Sonker and the answers received need to be analysed (Sonker, 2016).

The other questions raised by Neelam Sonker (Sonker, 2016) were on details of forest land encroachment in India, steps being taken by the Government to check forest encroachment and details of the incentives being given by the Government to increase the forest cover. The answer to the question regarding forest encroachment stated that 1.48 million hectares of forest land are under encroachment (Sonker, 2016). On the question of the government's financial incentives to increase the forest cover, the answer revealed that 3962.6 million Indian Rupees had been spent in 2014-15 & 2015-16 by the government (Sonker, 2016). This expenditure was on three afforestation schemes, namely the National Afforestation Program(NAP), Intensification of Forest Management Scheme(IFMS), and Green India Mission(GIM) (Sonker, 2016).

Now, one may wonder if the climate change mitigation efforts may have been more effective had afforestation been carried out on the 1.48 million hectares of forest land under encroachment.

1.3. India's forests and their carbon sequestration capacity

Forest land available for afforestation is limited. Forest in India is a tract of land legally proclaimed to be one under the Indian Forest Act, 1927 or Forest (Conservation) Act,1980 (Parliamentary Standing Committee, 2019). In India there are three types of legal forests under the Indian Forest Act,1927 (Government of India, 1927): Reserved forests (RF), Protected Forests (PF), and Unclassed Forests (UF)(Parliamentary Standing Committee, 2019). India has a notified forest area of 76.79 million hectares (m ha), comprising 43.47 m ha of Reserved, 21.94 m ha of Protected and 11.38 m ha of Unclassed (unclassified) Forests (Parliamentary Standing Committee, 2019).

Studies have found that planted forests/woodlots have the highest CO_2 removal rates, ranging from 4.5 to 40.7 t CO_2 ha^{-1} $year^{-1}$ during the first 20 years of growth(Bernal et al., 2018). Therefore, additionally, a minimum of 6.66 to a maximum of 60.236 million t CO_2 $year^{-1}$ could have been sequestered for the first 20 years of growth on the 1.48 million hectares of forest land under encroachment. There also exist other concerns on India's efforts to meet its forestry NDC goal of ensuring sequestration of 2.5-3 billion tonnes of CO_2 equivalent through additional afforestation by 2030 (Mathur et al., 2021).

1.4. Dearth of unequivocal answers on forest land encroachment

The concern with which the people of India view encroachment on forest land can be inferred from the frequent questions asked by the people's representatives in the Indian Parliament to the Government of India. Apart from the question on encroachment on forest land raised in the 16^{th} Lok Sabha, questions on the same have been raised by other parliamentarians in the 17^{th} Lok Sabha also, in 2020 (Kaushik and Saikia, 2020), and 2021 (Chand, 2021).

The information on forest land under encroachment provided through the reply to Lok Sabha questions in 2016 (Sonker, 2016), and in 2021 (Chand, 2021) reveals that 13 states/union territories (n=13/31) reported an increase, 15 (n=15/31) reported a decrease, and 8 (n=8/31) reported no change. However, these reports (Sonker, 2016,Chand, 2021) lack detailed information on new encroachments detected in the year and encroachment evicted in the year, due to which a year-on-year dynamic view of combating encroachment cannot be ascertained. These reports (Sonker, 2016,Chand, 2021) are also not providing information on the duration, type of encroachments as well as their numbers, for example, Roads(since 2018)-0.05 million km or Buildings(since 2000) -0.5 million or Buildings(since 1990)-0.8 million or Agricultural fields(since 2003)-0.3 million or Rubber Plantation(since 1998)-0.1 million hectares.

1.5. Challenges

The shortage of staff to monitor all the remote forest areas (Times of India, 2019,Times of India, 2021) makes the classification of encroachment based on types like buildings, roads, fields, and others challenging. There is

also an absence of an openly available GIS map of forest encroachments in India, which could have been helpful for different anti-encroachment activities. Reducing human involvement in quantifying forest land encroachment may be a solution to get accurate figures. These issues may hamper timely eviction of encroachment to carry out afforestation in such reclaimed areas. The planting of species with fast growth and high CO_2 sequestrating ability in the location could have otherwise aided India's efforts to meet its forestry INDC goal of ensuring sequestration of 2.5-3 billion tonnes of CO_2 equivalent through additional afforestation by 2030.

1.6. Contours of a solution

Therefore, in reference to the paragraphs above, there is a need to quantify, classify, and geo-reference encroachment on forest land through automation. To achieve the above, remote sensing in the form of Very High Resolution(VHR) satellite imagery or drone imagery may be required. In India already satellite imagery has been used to assess the forest land area under encroachment in the north eastern state of Manipur (Sastry et al., 2007). However, this study (Sastry et al., 2007), cannot classify the encroachments in the form of the number of buildings or roads. It has given only the area under different types of encroachment. This issue is crucial because all the buildings, roads, agricultural fields within forest land may not be illegal. The suspected buildings, roads and others may be legally built or legalised through the diversion of forest land for non-forestry purposes (Government of India, 1980) or under the Forest Rights Act (Government of India, 2006) or regularised before the enactment of Forest Conservation Act 1980 (Government of India, 1980) or constructed by the State Forest Departments(SFDs) themselves. Therefore, only an assessment of built-up area or agricultural fields area (Sastry et al., 2007) may not be sufficient to distinguish the illegal from the legal.

A system that can rapidly identify any new encroachment on forest land is required to nip at the bud any such efforts. This system could be on the lines of Forest Survey of India's Fire Alert System (FAST) Version 3.0 ("FSI Fire Alert System (FAST) Version 3.0 ", 2019). Artificial intelligence methods in general and Computer vision in particular like image classification, image/semantic segmentation, and instance recognition may be necessary in this situation (Szegedy et al., 2016;Szeliski, 2011;Girshick et al., 2014;Haralick and Shapiro, 1985;L.-C. Chen et al., 2017).

This paper attempts to ascertain if the different types of forest encroachments happening in India can be automatically identified using existing artificial intelligence methods from VHR remote sensing imagery and distinguish the legal from the illegal.

Also, a method is proposed to develop a web GIS portal for viewing locations of encroachments and monitoring their eviction followed by afforestation.

2. Literature Review: AI Methods for Forest Encroachment Detection

2.1. AI for Building Detection in Remote Forest Areas

There are several means to extract buildings from satellite imagery using artificial intelligence techniques like image classification, semantic segmentation and instance segmentation (L.-C. Chen et al., 2017;Haralick and Shapiro, 1985). From only three-channel RGB satellite imagery, using a modified DeeplabV3+ module with a Dilated ResNet backbone, building footprints masks were generated with the incorporation of F-Beta objective by Jiwani et al in 2021 (Jiwani et al., 2021;Baheti et al., 2020). In 2021 Arndt et al identified that deep neural networks perform better in classifying urban buildings over different cities using diverse satellite imagery collections (Arndt and Lunga, 2021). QGIS an open-source RS/GIS software also has plugins for the identification of buildings and construction sites (GeoAlert, 2022). Using such tools initially may be useful since different state forest departments, and national agencies use ArcGIS/QGIS software.

2.2. AI for Road Network Identification on Forest Land

Road extraction from satellite imagery is necessary to identify illegally constructed roads in forest land. Such roads may be used by encroachers, timber smugglers, and wildlife poachers to expand their illegal activities. Artificial intelligence techniques are being used successfully by different researchers for road extraction.

Abdollahi et al found in 2020 that VNet+CEDL deep learning model was able to preserve boundary information and obtain high-resolution road segmentation maps from satellite imagery (Abdollahi et al., 2020). Rural roads detection from satellite imagery has been improved by an ensemble Wasserstein Generative Adversarial Network with Gradient Penalty (WGAN-GP) method called E-WGAN-GP by Yang et al in 2020 (Chuang Yang and Z. Wang, 2020), crucial for use in forest areas. Plugins capable of detection of roads are available with QGIS (GeoAlert, 2022).

2.3. AI for Agricultural Field Detection

Various researchers have applied different artificial intelligence techniques for the extraction of agricultural fields and identification of crops, a few are mentioned here.

Even with cloud cover, using deep learning, crop mapping was carried out from one shot hyperspectral satellite imagery by Meng et al in 2021 (Meng et al., 2021). Agricultural field boundaries in northern Germany were extracted by Wagner et al in 2020 from sensor independent RGB imagery using a combination of deep learning models and graph-based growing contours (GGC) method (Wagner and Oppelt, 2020). Crop type detection was carried out on RGB imagery from UAVs using Deep learning and transfer learning by Chew et al in 2020 in Rwanda (Chew et al., 2020). Paddy fields, which may constitute a large part of forest encroachments, were classified using deep learning from Dual Polarized Synthetic Aperture Radar (SAR) imagery by Chatterjee et al in 2020 (Chatterjee et al., 2021).

2.4. AI for Mine Detection

Illegal mining and tailings dams were detected in Brazil using deep neural networks and Sentinel-2 imagery processed in Google Earth Engine by Blaniuk et al (Balaniuk et al., 2020). They have brought to light 263 illegal mines using freely available low-cost data science tools (Balaniuk et al., 2020), which can be replicated in India also.

2.5. AI for Illegal Plantation and Tree Species Detection

There are several methods for tree species identification and tree crown detection, which may be used to identify illegal plantations in forest land. In 2020 Miyoshi et al were able to identify individual tree species in a dense forest area of semi-deciduous forest of the Brazilian Atlantic biome, from hyperspectral imagery using deep learning (Miyoshi et al., 2020). Individual Tree-Crown Detection and Species Classification were achieved by Pleşoianu et al using a Deep Learning Ensemble Model in 2020 (Pleşoianu et al., 2020).

2.6. AI for Deforestation Detection

Deforestation is a tell-tale sign of forest encroachment, and researchers worldwide are now using artificial intelligence for detecting and predicting it.Adarme et al in 2020 evaluated the effectiveness of four different deep learning models for automatic deforestation detection in Brazilian forests, finding Early Fusion (EF) and Siamese Network (SN) to be the most effective (Ortega Adarme et al., 2020). Deforestation probability assessment was carried out in Eastern India by Saha et al using multi-layer perceptron neural nets with hybrid ensemble classifiers in 2021 (Saha et al., 2021). In 2020 Irvin et al have classified the primary drivers of deforestation using a deep learning model called ForestNet in Indonesia, this may be of relevance for India also (Irvin et al., 2020).

3. India Case Study: Application Context and Challenges

3.1. Types of encroachments on forest land in India

The encroachment of forest land in India include construction of buildings, mining, agriculture, roads, illegal plantations, and all other land-related non-forestry activities within legal forest boundaries in contravention of different laws in India(Government of India, 1927, 1980, 2006; Kh et al., 2013). Illegal buildings in forest land have been reported from different states of India (Kerala High Court, 2021; National Green Tribunal, 2019).

The forests of the mineral-rich states of India have been affected by illegal mining (Kanchi Kohli, 2014; Ministry of Environment,Forests,Climate Change, 2021; Supreme Court of India, 2005). Encroachments are also in the form of illegal rubber plantations, cannabis and others (Ankur Paliwal, 2018; Times of India, 2020). Large scale deforestation is often a prelude to encroachment in Forests, therefore they also need to be monitored.

3.2. Current State of Forest Land Data in India

3.2.1. Availability of Geo-referenced Forest Land Data

In connection with the Lafarge Umiam Mining Pvt. Ltd. vs Govt of India W.P.(C) No.-000202-000202 / 1995, the Hon'ble Supreme Court of India issued guidelines for dealing with such future cases on 6th July 2011 (Kapadia, 2011). The guideline number (vii) at page 107 (Kapadia, 2011, p. 107) reads as follows -

> (vii) Creation and regular updating of a GIS based decision support database, tentatively containing inter-alia the district-wise details of the location and boundary of (i) each plot of land that may be defined as forest for the purpose of the Forest (Conservation) Act, 1980; (ii) the core, buffer and eco-sensitive zone of the protected areas constituted as per the provisions of the Wildlife (Protection) Act, 1972; (iii) the important migratory corridors for wildlife; and (iv) the forest land diverted for non-forest purpose in the past in the district. The Survey of India toposheets in digital format, the forest cover maps prepared by the Forest Survey of India in preparation of the successive State of Forest Reports and the conditions stipulated in the approvals accorded under the Forest (Conservation) Act, 1980 for each case of diversion of forest land in the district will also be part of the proposed decision support database.

As per this guideline of the Hon'ble Supreme Court of India, almost all states have completed or are in the process of completion of geo-referencing of forest land in their respective states. States like Odisha have even developed an Android mobile application called "KYFL @ ODISHA (Know Your Forest Location in Odisha)" (ORSAC, 2022a).

The guideline number (xii) (Kapadia, 2011, p. 110) also speaks of preparation of Geo-referenced district forest maps,as seen below-

> (xii) Completion of the exercise undertaken by each State/UT Govt. in compliance of this Court's order dated 12.12.1996 wherein inter-alia each State/UT Government was directed to constitute an Expert Committee to identify the areas which are "forests" irrespective of whether they are so notified, recognized or classified under any law, and irrespective of the land of such "forest" and the areas which were earlier "forests" but stand degraded, denuded and cleared, culminating in preparation of *Geo-referenced district forest-maps* containing the details of the location and boundary of each plot of land that may be defined as "forest" for the purpose of the Forest (Conservation) Act, 1980.

3.2.2. Geo-referenced Dataset of Legal Activities on Forest Land

Areas with buildings, roads, fields, rubber plantations and others within forest land that are legal and need to be excluded from encroachment identification exercise are-

1. Areas diverted for non-forestry purposes under the Forest (Conservation) Act 1980 Government of India, 1980. Till now 3,28,979 hectares of forest land have been diverted (Forest Survey of India, 2022b).
2. Buildings/roads/Forest Nurseries other structures built by the State Forest Department
3. Areas distributed under The Scheduled Tribes and Other Traditional Forest Dwellers (Recognition of Forest Rights) Act, 2006 (Government of India, 2006). As of 30.11.2019 12.96 million acres or 5.24 million hectares of forest land has been distributed under this Act (Ministry of Tribal Affairs, 2020).
4. Areas given on lease for various purposes by the State Governments before the enactment of Forest (Conservation) Act 1980 (Government of India, 1980)

GIS polygons of diverted land (DL) as mentioned in sl no. 1 above, are available in the E-Green Watch portal of Forest Survey of India (Forest Survey of India, 2022a, 2022b). These may be merged to form a layer of diverted land for the entire country. This may also help ensure that construction/other activities are not taking place outside the approved area. Different State Forest Departments are having survey and GIS analysis units, which may be having the required spatial information as mentioned in sl no. 2 above. If not available, such spatial information can be easily prepared. Concerning areas as mentioned in sl no.3 above, states like Odisha and Tripura are carrying out GIS mapping using Android mobile apps (ORSAC, 2022b, 2022c).

Regarding land given under lease before the enactment of the Forest (Conservation) Act 1980 (Government of India, 1980), the leases if expired will have to be renewed as per the provisions of Forest (Conservation) Act 1980 (Government of India, 1980) which will provide GIS polygon data of such land in E-Green Watch portal (Forest Survey of India, 2022a, 2022b).

3.3. Implementation Challenges

3.3.1. Data Availability and Quality Challenges

Implementation of AI-based forest encroachment detection in India faces significant data availability and quality challenges that must be addressed for successful deployment. The absence of India-specific training datasets for various encroachment types represents a major obstacle, as most existing AI models are trained on Western architectural styles and landscapes that differ substantially from Indian contexts. Additionally, the high temporal variability of Indian landscapes due to pronounced seasonal changes (monsoon versus dry season) necessitates multi-seasonal imagery to avoid false positives. Cloud cover presents another persistent challenge, particularly in the northeastern states and Western Ghats where cloud-free days are limited, potentially creating significant gaps in monitoring continuity. Furthermore, the highly fragmented nature of both legal and illegal activities in Indian forests, with small-scale encroachments often measuring less than 0.1 hectares, demands very high resolution imagery that may be costly or difficult to acquire at national scales.

3.3.2. Technical Challenges

The technical implementation of an AI-based encroachment detection system encounters several formidable challenges related to both computational requirements and algorithmic limitations. The sheer scale of India's forest cover (approximately 77 million hectares) necessitates substantial computational infrastructure for processing high-resolution imagery at a national level, particularly when temporal analysis is required to detect new encroachments. Algorithm performance varies significantly across India's diverse biogeographic zones, with models trained in the relatively open deciduous forests of central India often performing poorly in the dense evergreen canopies of the Western Ghats or the complex mountainous terrain of the Himalayas. Technical expertise represents another limitation, as many state forest departments lack specialized personnel trained in advanced geospatial AI techniques, creating a knowledge gap between research capability and operational implementation. Furthermore, distinguishing between legal and illegal activities through automated means requires complex rule sets that can incorporate numerous exceptions and special cases that vary by region and legal framework, adding significant complexity to model development and validation protocols.

3.3.3. Administrative and Political Barriers

The implementation of an automated forest encroachment detection system in India confronts multifaceted administrative and political barriers that extend beyond technical considerations. Forest management in India operates under a complex jurisdictional framework where responsibilities are distributed across central, state, and local authorities, creating coordination challenges for implementing a unified monitoring system. Politically sensitive issues surrounding forest rights, particularly those related to indigenous communities under the Forest Rights Act of 2006, require careful handling to avoid potential conflicts when automated systems flag activities that may be legally contested or in regulatory gray areas. Additionally, cross-departmental coordination between Forest, Revenue, and Tribal Affairs departments—each maintaining separate and some-

times contradictory land records—presents significant administrative hurdles for creating a consistent reference layer of legal activities. The system's implementation may also face resistance from vested interests benefiting from the current opacity in encroachment reporting, as increased transparency could threaten established patronage networks or expose previous administrative failures in preventing forest loss.

3.3.4. Resource and Cost Constraints

The development and implementation of a comprehensive AI-based forest encroachment detection system faces significant resource and cost constraints that must be realistically addressed for sustainable operation. Acquisition of very high resolution (VHR) satellite imagery presents a substantial recurring expense, with commercial providers charging approximately $10-25 per square kilometer, potentially amounting to millions of dollars annually for comprehensive national coverage of priority forest areas. Hardware infrastructure requirements for processing and storing massive imagery datasets represent another major cost center, necessitating either substantial capital investment in computing infrastructure or ongoing cloud computing expenses. Human resource costs for system development, operation, and field verification teams constitute a significant operational expense, requiring specialized personnel who command higher salaries than typical forestry staff. Additionally, the development of India-specific training datasets through professional annotation services represents a substantial initial investment, potentially costing $150,000-300,000 for comprehensive coverage of all encroachment types across India's diverse biogeographic zones, though this represents a one-time expense that could be partially offset through academic partnerships and crowdsourcing initiatives.

3.3.5. Need for Regular Updates and Maintenance

A forest encroachment detection system requires systematic regular updates and maintenance to remain effective, creating operational challenges beyond initial implementation. AI models require periodic retraining to address concept drift as encroachment patterns evolve over time, with encroachers potentially adapting their methods to avoid detection once they become aware of monitoring systems. The underlying base maps of forest boundaries and legal activities require constant updating as new land is legally diverted for non-forestry purposes, rights are granted under the Forest Rights Act, or forest boundaries are modified through legal processes. Technical infrastructure demands regular software updates, security patches, and hardware upgrades to maintain system performance and protect sensitive data from emerging cybersecurity threats. Additionally, the verification feedback loop must be continuously maintained through field staff training and engagement to ensure ground-truthing data continues flowing back into the system, preventing degradation of model accuracy over time. This continuous improvement cycle requires institutional commitment to long-term funding and staffing that transcends typical government project cycles, necessitating dedicated budget lines and performance metrics tied to system maintenance rather than just initial deployment.

4. Methodology: Framework for AI-based Encroachment Detection

4.1. Preparation of AOI for analysis

The area of interest(AOI) of remote sensing imagery where the encroachment identification processes (explained in 2.1) will be applied, has to be first determined.

$$AOI = L_{ForestLand} - L_{Legalactivities} \tag{1}$$

where:

AOI= Area of Interest to check for encroachment using artificial intelligence
$L_{\textbf{Forest Land}}$**=** GIS layer of forest land
$L_{\textbf{Legal activities}}$**=** GIS layer of the area to be excluded from checking for any encroachment identification exercise

The Forest Land layer comprises legally designated forests under the Indian Forest Act, 1927, including Reserved Forests, Protected Forests, and Unclassed Forests. Following the Supreme Court of India guidelines

in the Lafarge Umiam Mining case (2011), most states have completed or are finalizing geo-referencing of their forest boundaries, with some states like Odisha developing mobile applications for public access to this information.

The Legal Activities layer must include four categories of authorized non-forest use: (1) areas diverted for non-forestry purposes under the Forest Conservation Act 1980 (approximately 328,979 hectares); (2) infrastructure built by State Forest Departments; (3) lands distributed under the Forest Rights Act 2006 (approximately 5.24 million hectares); and (4) pre-1980 leases granted by state governments. GIS data for these exemptions is available through the E-Green Watch portal, state Forest Department GIS units, and state-level FRA implementation tracking systems.

4.2. Data Requirements and Dataset Development

4.2.1. Preparation of India specific datasets and training of models

The success of any artificial intelligence project depends on the quality of datasets used for training the machine/deep learning model (H. Chen et al., 2020; Ding and Li, 2018). Therefore, to get accurate results we need to have India specific datasets for each encroachment type like buildings, road networks, agricultural fields, mines and plantations.

Currently, no comprehensive India-specific remote sensing datasets exist for these encroachment types. Existing repositories like Kaggle offer datasets for Western contexts (e.g., Massachusetts Roads and Buildings Datasets (Mnih, 2013)) but lack representation of Indian landscapes and settlement patterns. The development of India-specific datasets would provide significant benefits beyond encroachment detection, supporting broader geospatial AI applications throughout the country.

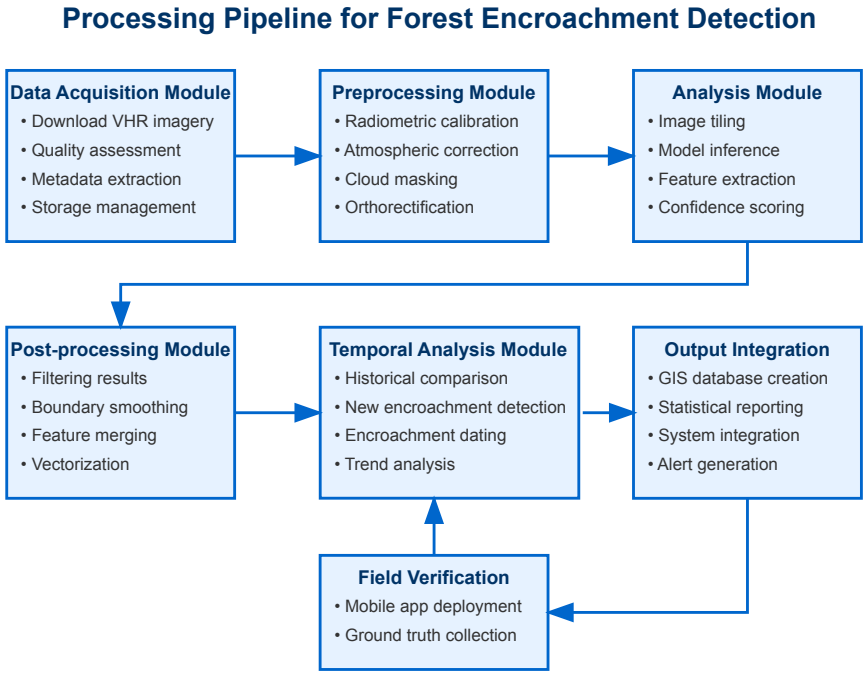
4.2.2. Data Collection Protocols and Standards

To ensure dataset quality and consistency, standardized protocols must be established regarding Imagery specifications, Annotation standards, Quality control process and Data augmentation. Data collection efforts should prioritize biogeographic representativeness, ensuring samples from all forest types in India (tropical, subtropical, montane, etc.) and capturing seasonal variations that significantly affect feature visibility and appearance.

4.3. Model Selection and Training Process

4.3.1. Criteria for Model Selection Based on Indian Conditions

Model selection must consider India's unique geographical and technical context like Performance across diverse landscapes, Resilience to seasonal variations, Computational efficiency and Adaptation to data limitations. Based on literature review, recommended model architectures include DeepLabV3+ with DenseNet backbone for building detection, MFPN (Multiple Feature Pyramid Network) for road detection, ResuNet-a for agricultural field boundaries, and enhanced Mask R-CNN for mining operations.



4.3.2. Training and Validation Protocols

A rigorous training and validation framework is essential for reliable model performance through Dataset partitioning, Hyperparameter optimization, Cross-validation strategy and Evaluation metrics. The testing and validation pipeline should explicitly include challenging scenarios (monsoon-affected imagery, partially obscured features, terrain shadows) to ensure robust real-world performance beyond ideal conditions.

4.4. Implementation Architecture

4.4.1. Processing Pipeline for VHR Satellite Imagery

Fig. 1 – Processing Pipeline

The operational implementation requires a structured processing pipeline(Fig. 1). The processing results will create geo-referenced databases of semantically segmented encroachment features that can be integrated with administrative boundaries to generate state-wise and district-wise statistics. This historical perspective is particularly valuable for legal proceedings and policy development, providing a chronological record of encroachment patterns.

4.4.2. Integration with Existing GIS Systems

The encroachment detection system must integrate seamlessly with existing government platforms like Forest Survey of India systems, State Forest Department GIS and National geospatial infrastructure. The integration architecture should employ standard OGC-compliant web services (WMS, WFS) for data sharing, with appropriate access controls to manage sensitive information while promoting transparency.

4.5. Validation and Verification Framework

4.5.1. Web GIS Platform Design

An interactive Web GIS platform (Fig(s). 2,4) will provide visualization and management capabilities. The platform design should follow the successful model of FSI's Forest Fire Portal, which has demonstrated effective integration of remote sensing alerts with field verification workflows at the national scale.

4.5.2. Ground Verification Protocol

Suspected encroachments identified by the AI system require field verification using mobile application and verification workflow. Once verification is complete, the web platform will enable tracking of both verification progress and subsequent enforcement actions, providing transparency for all stakeholders including policy-makers, judiciary, and citizens.

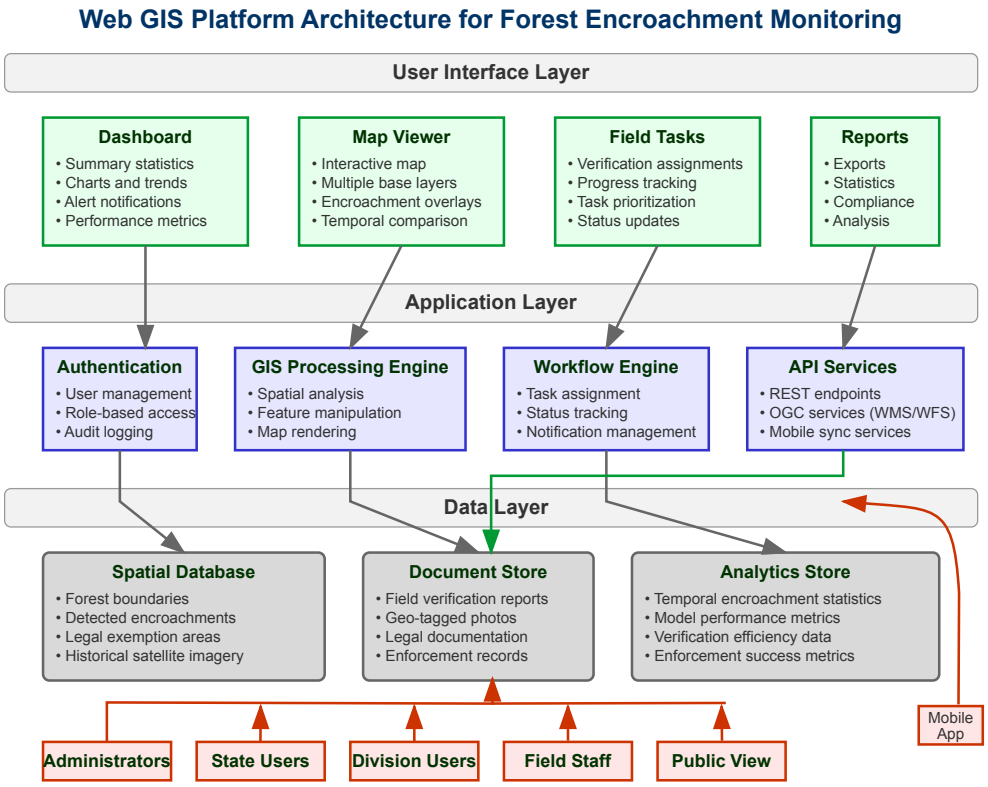


Fig. 2 – WebGIS Platform Architecture

4.5.3. Continuous Improvement through Feedback

The system design must incorporate feedback loop mechanisms for ongoing enhancement. This continuous improvement framework ensures the system evolves to address emerging encroachment patterns and adapts to regional variations in effectiveness, ultimately creating a learning system rather than a static monitoring tool.

5. Results and Discussion: Global Applications and Policy Implications

5.1. Lessons from India Applicable to Other Countries

The study of forest encroachment in Jiribam Sub-Division of Manipur (Kh et al., 2013) offers valuable insights applicable to similar challenges globally. As demonstrated in the Jiribam study, the application of remote sensing and GIS technologies allowed researchers to identify that 21.22% of the total area was under encroachment, primarily due to shifting cultivation practices (Kh et al., 2013).

In the Brazilian Amazon, where deforestation for agriculture is a significant concern, the Indian approach of combining high-resolution satellite imagery with ground verification could enhance existing monitoring systems by detecting smaller encroachments before they expand. Brazil's existing DETER system (Doblas et al., 2022) could be supplemented with AI-based detection to improve early intervention capabilities in remote areas.

5.2. Policy Implications for Forest Conservation

The findings from India's encroachment detection work suggest several important policy implications for forest conservation globally.

Integrated Jurisdictional Approaches: Forest monitoring technologies must be embedded within comprehensive jurisdictional frameworks that connect detection with enforcement and restoration. The Jiribam study

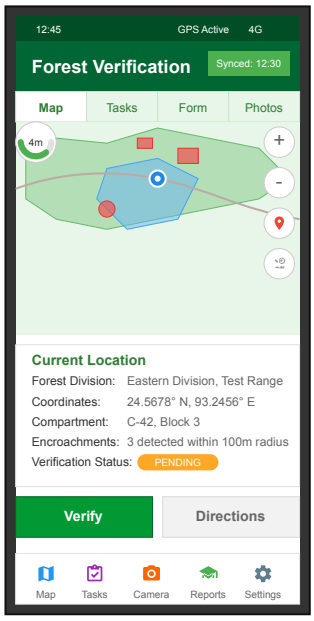

Fig. 3 – Field Verification Mobile Application Mock Up

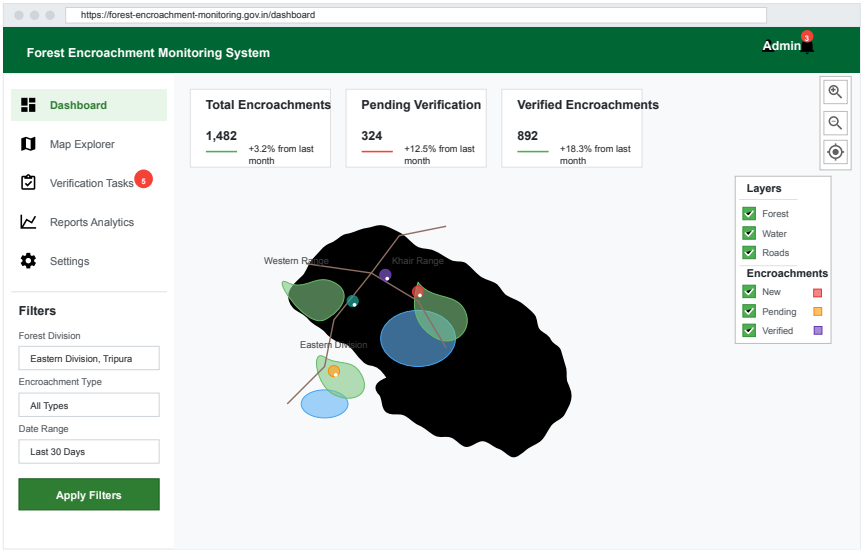

Fig. 4 – Desktop Web Application Mock Up

showed that merely identifying encroachment is insufficient; responding to it requires coordinated action across departments (Kh et al., 2013). Policy frameworks should establish clear protocols for inter-agency coordination when encroachment is detected.

Addressing Root Causes: The Jiribam study identified shifting cultivation as the primary driver of encroachment, with socio-economic factors like "food habits and misconceived food security feelings" contributing to continued forest clearance (Kh et al., 2013). Effective policies must address these root causes through alternative livelihood development and sustainable agriculture initiatives rather than focusing solely on enforcement.

Community Engagement: The recommendation from the Jiribam study to "manage jhum affected areas...without neglecting the demands and needs of the farmers" (Kh et al., 2013) emphasizes the importance of community-based conservation approaches. Policies should recognize indigenous and traditional forest rights while providing pathways to more sustainable practices through collaborative management. Technology Access and Standardization: For monitoring systems to be effective globally, policies need to support technology transfer, capacity building, and data standardization. The methodologies used in India can be adapted to different contexts, but require policy frameworks that enable access to satellite imagery, analysis software, and training for local forestry officials.

5.3. Integration with Climate Change Mitigation Efforts

AI-based encroachment detection systems directly support global climate change mitigation efforts, particularly within frameworks like REDD+ (Reducing Emissions from Deforestation and Forest Degradation) (Duchelle et al., 2018). This can be achieved through Enhanced Carbon Accounting, Supporting Results-Based Payments, Addressing Forest Degradation and Protecting Ecosystem Services.

5.4. Recommendations for Implementation in Various Contexts

Based on the Indian experience and the Jiribam study in particular, implementation recommendations can be tailored to different contexts:

For National Governments:

1. Establish comprehensive legal frameworks that clearly define forest boundaries
2. Develop institutional coordination mechanisms between rstakeholders
3. Invest in capacity building for technical staff at multiple levels of government
4. Create transparent monitoring dashboards that promote accountability and public engagement

For Conservation Organizations:

1. Support development of regionally-specific training datasets for AI algorithms
2. Facilitate technology transfer and capacity building between countries facing similar challenges
3. Develop community-based monitoring protocols that complement satellite detection
4. Advocate for funding mechanisms that support sustained monitoring rather than short-term projects

For Development Partners:

1. Fund pilot implementations that demonstrate effectiveness in different contexts
2. Support creation of regional centers of excellence for technology adaptation
3. Integrate encroachment monitoring with broader sustainable development initiatives
4. Invest in alternative livelihoods for forest-dependent communities

6. Conclusion

This paper demonstrates that current artificial intelligence techniques provide a viable foundation for automating forest encroachment detection in India. The comprehensive framework proposed here—integrating deep learning models with GIS systems, field verification protocols, and administrative workflows—addresses a critical need in forest conservation governance. By enabling systematic monitoring of encroachments through building detection, road network identification, and land use classification, this approach could substantially increase available land for afforestation efforts. The implementation challenges identified—including data availability, computational requirements, and administrative coordination—while significant, can be addressed through phased deployment, starting with high-priority forest regions.

Beyond theoretical potential, next steps should include pilot implementations across diverse biogeographic zones, development of India-specific training datasets, and quantitative evaluation of model performance under varying seasonal conditions. The long-term success of such a system depends not merely on technical implementation, but on integration with existing governance structures and community engagement initiatives. If successfully deployed, this approach could serve as a model for other forest-rich nations facing similar challenges, ultimately contributing to global climate change mitigation efforts by protecting the carbon sequestration potential of forest ecosystems. The return on investment—both environmental and economic—justifies the resources required for implementation, particularly as India strives to meet its commitment of creating an additional carbon sink of 2.5-3 billion tonnes of CO_2 equivalent by 2030.

Acknowledgement

I acknowledge the support I received from the editorial board and reviewers of the Dg.o2025 conference for their valuable feedback and guidance that significantly enhanced the quality of this paper. Their constructive comments helped refine the methodology and strengthen the analytical framework. I also extend my gratitude to my family and friends for their continued encouragement throughout the research and writing process.

Track 6: Digital Government Cybersecurity Management: Paradoxical Tensions and Responsible Innovation

Track Description

There are paradoxical tensions in public-sector cybersecurity management, alongside approaches to responsible innovation for an equitable digital government ecosystem. Innovation is oriented toward fast-paced technological adoption that may be high-risk; cybersecurity measures moderate the pace while aiming to lower organizational risk. This paradoxical tension between innovation and security can exacerbate digital government inequities. Resource-constrained public organizations may lead to low-level tech adoption and inadequate security measures. Marginalized communities could be left behind in the digital ecosystem, making them more susceptible to exploitation. Public sector management needs to adopt technological innovation holistically, in a responsible way, while considering organizational cybersecurity risks. Towards this end, this track aimed to examine the intersecting dimensions of organizational cybersecurity risks and responsible innovation in the public sector to build a more inclusive, equitable digital government ecosystem.

Submitted: 31 January 2025, Revised: 26 March 2025, Accepted: 21 April 2025, Published: 13 June 2025

Abstract. The rapid digitization of public sector services has fundamentally reshaped how governments operate, manage resources, and interact with citizens. From digital identity platforms to AI-enabled service portals, technology enables faster decision-making, seamless operations, and more responsive governance. Yet, this digital transformation introduces growing cyber risks, including ransomware, insider threats, and nation-state attacks. These risks not only threaten data privacy and national security but also undermine service reliability and institutional trust. To mitigate such threats and sustain innovation, cybersecurity hardening has emerged as a critical enabler of government efficiency. It includes proactive strategies such as continuous threat monitoring, network segmentation, encryption, and Zero Trust frameworks that reinforce operational continuity. While existing literature often frames cybersecurity as a compliance necessity, our research recasts it as a core strategic asset for enhancing public service performance. Specifically, we examine how cybersecurity contributes to resilience, reduces service disruptions, and improves resource allocation—three pillars of efficient governance. This approach aligns with emerging policy shifts, notably the formation of the U.S. Department of Government Efficiency (DOGE) in January 2025, which identifies cybersecurity as central to improving operational outcomes. Supported by similar initiatives in Texas, Kansas, and Louisiana, this paper situates cyber defense as a linchpin of modern administrative reform. By exploring real-world breach case studies and integrating economic modeling with cybersecurity strategy, we demonstrate how protecting systems is not just a cost-saving imperative but a means to power smarter, faster, and safer governance.

Keywords. Cybersecurity Hardening, Government Efficiency, Risk Management, Automation, Cost-Benefit Analysis.

1. Introduction

The digitization of government services has transformed public administration, enabling efficient resource management, streamlined operations, and enhanced citizen engagement. From online tax filings to e-governance platforms, technology has become integral to the functioning of modern governments. However, this increasing reliance on digital infrastructure has also made governments vulnerable to an array of cybersecurity threats, including ransomware, data breaches, and state-sponsored cyberattacks. The consequences of these threats are far-reaching, impacting not only operational continuity but also national security, public trust, and the overall efficiency of government systems. Cybersecurity hardening has emerged as a critical strategy to mitigate these risks. This involves implementing advanced measures such as encryption, network segmentation, and continuous threat monitoring to safeguard sensitive data and ensure uninterrupted service delivery. While the technical aspects of cybersecurity hardening are well-documented, its broader implications for government efficiency remain underexplored. This paper examines how enhancing cybersecurity measures can improve the operational efficiency of government agencies, reduce costs associated with cyber incidents, and build resilience in the face of evolving threats. Government efficiency refers to the ability of public agencies to deliver services, manage resources, and execute operations in a timely, cost-effective,

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

and streamlined manner that maximizes public value and minimizes waste or redundancy.

The intersection of cybersecurity and government efficiency highlights the critical role of robust digital transformation in modern governance, where technology streamlines operations, enhances service delivery, and fosters effective decision-making. Centralized data systems enable faster retrieval and updates, improving productivity and collaboration across departments while minimizing errors and redundancies. Real-time access to information equips decision-makers with actionable insights, transforming static data into dynamic tools for effective resource allocation. Digital transformation also fosters responsive public services, enabling governments to adapt to evolving priorities and citizen needs with agility. However, the rapid digitization of government operations exposes vulnerabilities to cyber threats such as data breaches and ransomware, which can disrupt services, compromise sensitive data, and erode public trust. Strong cybersecurity measures are essential to secure these digital systems, ensuring continuity of operations and reinforcing public confidence. By aligning cybersecurity with digital transformation efforts, governments can achieve operational resilience, sustain innovation, and deliver efficient, citizen-centric services in an increasingly complex digital landscape.

Drawing on computer science to analyze technical security measures, public administration to assess operational impacts, and economics to evaluate cost-benefit considerations, this study provides a holistic analysis of the intersection between cybersecurity and government efficiency. It includes case studies of significant government-related cyber incidents, shedding light on the financial, operational, and societal impacts of cyberattacks. By focusing on actionable strategies and policy recommendations, the study aims to inform decision-makers on how cybersecurity hardening can improve the operational efficiency of government agencies, mitigate the financial and operational impacts of cyber incidents, and build resilience against evolving cyber threats.

The U.S. Department of Government Efficiency (DOGE) has identified cybersecurity hardening as a cornerstone of its mission to optimize public service delivery and enhance the resilience of critical infrastructure (Gianfortune, 2025). As federal, state, and local governments accelerate their digital transformation efforts, the risk of cyberattacks has grown exponentially. High-profile incidents, such as the SolarWinds breach and the ransomware attack on the city of Atlanta, highlight the urgent need for robust cybersecurity measures to protect sensitive data and ensure the continuity of essential services.

The U.S. government has prioritized cybersecurity as a key component of its strategic goals, reflected in initiatives such as the Cybersecurity and Infrastructure Security Agency's (CISA) Continuous Diagnostics and Mitigation (CDM) program. These efforts aim to strengthen the security posture of federal agencies by providing real-time threat monitoring, vulnerability management, and automated incident response capabilities. Moreover, the Biden Administration's 2023 National Cybersecurity Strategy emphasizes public-private collaboration, supply chain security, and workforce development to address the growing complexity of cyber threats. (Jaikaran, 2023) Small- and medium-sized government entities face unique challenges, often lacking the resources and expertise needed to implement advanced cybersecurity measures. This paper underscores the importance of equipping such agencies with cost-effective tools and strategies to enhance their cyber resilience. By addressing these gaps, governments can minimize service disruptions, reduce remediation costs, and foster public trust in digital systems.

At its core, this research is motivated by the dual need to protect national assets and improve the efficiency of government operations. The focus on cybersecurity hardening not only aligns with DOGE's mission but also contributes to broader national priorities, including economic stability, public safety, and democratic integrity. By highlighting the intersection of cybersecurity and government efficiency, this paper seeks to provide actionable insights that support the development of resilient, cost-effective, and citizen-centric governance models.

2. Background

2.1. The rising cost of governance due to data breaches

As digitization accelerates, the frequency and sophistication of cyber threats continue to grow exponentially. The global cost of cybercrime is projected to surge from $9.22 trillion in 2024 to $13.82 trillion by 2028, as

shown in 1. This alarming trajectory emphasizes the critical need for robust cybersecurity measures. Additionally, IBM's 2024 report on data breach costs highlights the increasing prevalence of cybersecurity incidents, with the global average cost of a data breach reaching $4.88 million in 2024—a 15% increase since 2020.

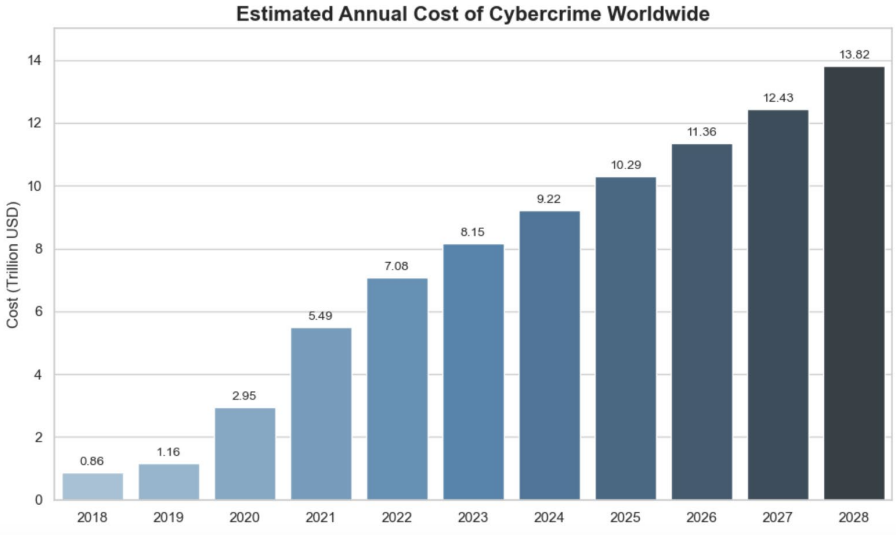

Fig. 1 – Estimated global cost of cybercrime and the rising cost of data breaches. Data sourced from Statista.

Governments and organizations face a diverse range of cyber threats, each with significant potential to disrupt operations and compromise sensitive information. Ransomware attacks, where malicious actors encrypt critical data and demand ransom payments for its release, pose a serious risk. For instance, the Costa Rica ransomware attack in 2022 paralyzed essential public services, causing widespread economic and operational damage (Nato, 2022). Phishing and social engineering tactics exploit human vulnerabilities through deceptive emails and messages to gain unauthorized access to systems (Kumar et al., 2024). Such attacks can lead to data breaches, as evidenced by the 2015 Office of Personnel Management (OPM) hack, where stolen credentials compromised millions of sensitive records (Gootman, 2016). State-sponsored cyber espionage, often in the form of advanced persistent threats (APTs) backed by nation-states, targets critical infrastructure and sensitive government data. The SolarWinds hack of 2020 exposed vulnerabilities in numerous U.S. federal agencies, raising national security concerns (Alkhadra et al., 2021). Furthermore, Distributed Denial of Service (DDoS) attacks represent another significant threat. These attacks overwhelm systems with excessive traffic, disrupting essential services. Governments and public institutions often become targets, impeding their ability to serve citizens. The diverse nature of these cyber threats demonstrates the need for comprehensive cybersecurity strategies and robust defense mechanisms to protect critical infrastructure and sensitive information.
The impacts of these cyber threats extend beyond financial losses. They compromise public trust, disrupt essential services, and expose sensitive data, which can have long-term implications for national security and societal stability. Recognizing the direct correlation between the rate of digitization and the scale of cybersecurity risks, governments must prioritize cybersecurity hardening to mitigate these threats effectively and ensure the continuity of public services.

In December 2015, a significant data breach exposed personal information of around 191 million U.S. voters due to a misconfigured database that was publicly accessible without security measures. This breach revealed sensitive data, including names, addresses, and party affiliations. The lack of basic security protocols and poor database configuration underscored the need for stringent data security measures and clear data ownership. The breach delayed remediation and highlighted the importance of proper configuration management and ownership accountability (Finkle, 2015).

Similarly, in 2022, Costa Rica faced a series of devastating ransomware attacks that targeted 27 public institutions, including the Ministry of Finance and the Costa Rican Social Security Fund. The attackers demanded millions in ransom, leading to severe operational disruptions. The government's refusal to pay the ransom resulted in an estimated economic loss of $125 million within the first 48 hours. The attack paralyzed essential services, including tax systems and healthcare records, demonstrating the far-reaching consequences of

ransomware on public institutions and the economy. The national emergency declaration underscored the importance of robust cybersecurity defenses and incident response plans. (Nato, 2022)

While many governments have faced cyberattacks, some have proactively strengthened their security frameworks, preventing major incidents and ensuring the continued resilience of their digital infrastructures. Estonia, often hailed as a global leader in e-governance and cybersecurity, stands out with its robust infrastructure, including its Data Embassy and blockchain-secured systems (Bitton, 2022). These measures, combined with a focus on citizen education and strong public-private collaboration, have significantly reduced cyber incidents, bolstering the nation's digital governance. Estonia's proactive measures have established it as a leader in cybersecurity, setting an example for other nations. Similarly, Singapore, with its Smart Nation initiative, integrates both technological innovation and cybersecurity at its core. The country's Cybersecurity Act and the work of the Cybersecurity Agency of Singapore (CSA) have made cybersecurity a key element of the nation's digital transformation (Cyber Security Agency of Singapore, 2025). By embedding security measures within its evolving digital infrastructure, Singapore has ensured the secure and efficient delivery of public services, becoming a model for how digital security and innovation can work hand-in-hand. These case studies illustrate the financial and operational impacts that data breaches can have on both public institutions and private organizations. From the misconfigured U.S. voter database to the crippling ransomware attacks in Costa Rica, each incident highlights the urgent need for robust cybersecurity frameworks, proactive risk management, and swift incident response. In contrast, countries like Estonia and Singapore demonstrate the effectiveness of strategic investments in cybersecurity. With well-established national cybersecurity agencies, public-private collaborations, and innovative security technologies, these nations have created more resilient digital infrastructures. They've built strong foundations that have not only mitigated cyber risks but have also enhanced their ability to innovate securely in the digital age. While the United States has taken significant steps to bolster its cybersecurity, particularly through initiatives like the Cybersecurity and Infrastructure Security Agency (CISA) and the Continuous Diagnostics and Mitigation (CDM) program, these efforts, though valuable, are not enough. The U.S. has made progress in strengthening federal systems and reducing downtime, but as recent breaches have shown, there is still much work to be done to protect critical infrastructure. The country's current cybersecurity framework needs to evolve more rapidly to keep pace with the growing sophistication of cyber threats.

These successful models, however, provide valuable insights for nations and organizations seeking to safeguard their digital infrastructures. They show that the cost of data breaches goes far beyond financial losses—impacting public trust, operational continuity, and even national security. To mitigate these risks, governments and organizations must prioritize cybersecurity, continually adapt to emerging threats, and make significant investments in both technology and human resources. Only through these sustained, concerted efforts can we hope to build resilient digital governance frameworks capable of standing up to the challenges of an increasingly interconnected and cyber-vulnerable world.

2.2. Government Efficiency initiatives in the United States

The establishment of the US Department of Government Efficiency (DOGE) in January 2025 highlights the commitment of the federal government to improving operational efficiency through strategic technological and organizational measures. The formal purpose of DOGE, as stated in the executive order that established it, is to "modernize federal technology and software to maximize government efficiency and productivity" (The White House, 2025). Several U.S. states, including Texas, Kansas, and Louisiana, have recently undertaken similar initiatives to enhance government efficiency. In Texas, the Committee on Delivery of Government Efficiency has been formed to reduce inefficiencies, increase transparency, and promote the use of science and technology. (Texas House of Representatives, 2024). As digitization reshapes public administration, these organizations play a pivotal role in driving initiatives that ensure seamless service delivery while addressing systemic vulnerabilities. These initiatives focus on preventing service disruptions, safeguarding critical public services such as healthcare and emergency response, and optimizing resource allocation by reducing financial and reputational losses linked to cyber incidents. A key way to achieve this is through cybersecurity hardening - proactive securing systems to enhance resilience, reduce downtime, and ensure seamless operations. Strong cybersecurity prevents costly breaches, minimizes reactive spending, and compliance burdens while supporting DOGE's mission to cut inefficiencies. Hardened systems also foster trust in digital services, ensuring secure and frictionless operations. Without a strong security foundation, modernization efforts risk being undermined by cyber threats. Our approach helps to achieve the broader objectives of government efficiency while suggesting the addition of cybersecurity jobs and the reinvestment, leading to not only efficiency

of government operations, but also potentially avoiding multi-million dollar costs of data breaches. Our research demonstrates that cybersecurity improvements are integral to government efficiency by improving operational resilience, reducing the likelihood and impact of service disruptions, enabling smarter resource allocation, and strengthening public trust in digital infrastructure.

Sl	State	Committee Name	Cybersecurity Agenda
1	Kansas	Senate Committee on Govt Efficiency	Not specified
2	Louisiana	Fiscal Responsibility Program	Not specified
3	Texas	Committee on Delivery of Govt Efficiency	Cybersecurity, privacy, and identity theft

Tab. 1 – Government Efficiency Committees Launched in the USA (Oct 2024–Feb 2025)

2.3. The Role of Cybersecurity Hardening

The National Institute of Standards and Technology (NIST) defines hardening as the process of reducing attack opportunities by addressing vulnerabilities and disabling unnecessary services. Cybersecurity hardening is a holistic strategy designed to protect organizations from cyber threats and reduce risks. By limiting the attack surface, organizations can lower their susceptibility to breaches and bolster their overall security framework. Organizations can enhance cybersecurity hardening by addressing key vulnerabilities through measures like strengthening password security, replacing default passwords with strong, unique ones to prevent breaches, and providing regular employee and client training on emerging threats and best practices. Automated updates and patching are crucial for efficiently managing zero-day vulnerabilities across complex IT environments. Encrypting network traffic ensures sensitive data is protected during transmission, while regular audits help identify and resolve misconfigurations in servers, routers, firewalls, and other systems. These steps collectively reduce risks, safeguard data, and strengthen overall network security. To achieve a robust cybersecurity framework, organizations should regularly assess their data storage and sharing processes. This includes reviewing the security of collaboration tools and addressing any gaps in system configuration to mitigate risks effectively.

3. Related Work

3.1. Regulatory Frameworks and Governance

The regulatory landscape of cybersecurity has evolved significantly, with governments and organizations developing comprehensive frameworks to address emerging threats. This evolution is driven by the increasing frequency and sophistication of cyber attacks, as well as the growing importance of data protection and privacy. Karabacak et al., 2016 demonstrated how nations can develop and implement regulatory frameworks for critical infrastructure protection. This approach is mirrored in other countries, such as the United States, where sector-specific regulations like HIPAA for healthcare and FISMA for government agencies have been implemented (Federal Information Security Management Act of 2002, 2002; Health Insurance Portability and Accountability Act of 1996, 1996). The European Union has taken a more comprehensive approach with the General Data Protection Regulation (GDPR) and the Network and Information Systems (NIS) Directive, setting global benchmarks for data protection and network security.

Furthermore, Bechara and Schuch, 2021 examined the challenges of creating unified global regulatory standards, particularly highlighting the complexities of cross-border cooperation. This is evident in the difficulties faced by businesses operating internationally, who must comply with multiple, sometimes conflicting, regulations. Albalas et al., 2022 provided a foundational understanding of cybersecurity governance structures and their implementation across different sectors. This understanding is crucial as the regulatory landscape continues to evolve, with new cybersecurity rules being enacted in major economies worldwide in 2024. These new laws aim to provide enhanced cybersecurity guardrails to effectively counter evolving cyber threats, including those leveraging advanced technologies like artificial intelligence.

Adding to this body of work, Hiller et al., 2024 proposed an innovative approach that breaks away from traditional regulatory frameworks by introducing a ”carrots and sticks” tax strategy to incentivize stronger cybersecurity postures. Their framework for a Federal Cybersecurity Investment Tax Credit, combined with a cyber insecurity tax, offers a more flexible and adaptive approach to cybersecurity governance that goes beyond conventional compliance-based requirements.

3.2. Economic and Resource Allocation

The economic aspects of cybersecurity hardening remain a critical concern for organizations in 2025, as they navigate uncertain economic times (Kissoon, 2020). Despite the growing need for robust cybersecurity measures, businesses are scrutinizing their budgets closely. Recent studies indicate that cybersecurity budgets have seen slower growth, with average increases dropping from 17% to 6% year-over-year (Krishna & Sebastian, 2021). However, cybersecurity spending remains relatively resilient, accounting for an increasing proportion of total IT costs, rising from 8.6% in 2020 to 11.6% in 2023 (IANS Research & Artico Search, 2023). This trend reflects the strategic importance of cybersecurity in organizational growth and continuity plans. CISOs are facing pressure to justify their budgets, leading to a focus on cost-effective solutions such as automation and security tool consolidation. Organizations are prioritizing basic cyber hygiene practices over investing in new technologies, emphasizing the need to maximize the outcome of every dollar spent on cybersecurity (Argyridou et al., 2023). As the global cybersecurity spend approaches $100 billion annually, with potential losses nearing $1 trillion, the economic imperative for effective resource allocation in cybersecurity hardening has never been more apparent. (Falco et al., 2019)

3.3. E-Government Implementation

The incorporation of cybersecurity into e-government initiatives is crucial for ensuring their success and resilience. Alrubaiq and Alharbi, 2021 identify key cybersecurity threats in e-government implementations, including data breaches, denial-of-service attacks, and insider threats. Their study highlights the need for a comprehensive cybersecurity framework that addresses both technical vulnerabilities and human factors in e-government projects. Recent advancements in e-government implementation include the development of more sophisticated risk assessment models. Ganin et al., 2020propose a novel cybersecurity risk assessment framework specifically tailored for e-government applications, incorporating dynamic threat landscapes and interdependencies between different government systems. This approach allows for more accurate prediction and prioritization of potential vulnerabilities in government networks. The National Institute of Standards and Technology (NIST) has developed Cybersecurity Framework 2.0, which provides a comprehensive approach to managing cybersecurity risks in critical infrastructure, including e-government systems. This updated framework now emphasizes six core functions: Govern, Identify, Protect, Detect, Respond, and Recover, offering a structured approach to cybersecurity implementation in e-governance initiatives.(National Institute of Standards and Technology, 2024)

The concept of ”security by design” has gained significant traction in e-government implementations. Alreemy et al., 2016 propose a framework for integrating security considerations throughout the entire lifecycle of e-government projects, ensuring that cybersecurity measures are not an afterthought but are embedded in the design and development phases. This approach aligns with a demonstration by Conklin and White, 2006 of the practical value of cybersecurity exercises in strengthening government organizations' security posture and incident response capabilities. As e-government systems become more sophisticated and widespread, the need for robust, adaptive, and comprehensive cybersecurity strategies becomes increasingly important, necessitating ongoing research and development in this critical area.

4. Methodology

This study integrates qualitative and quantitative analyses to assess how cybersecurity hardening enhances government efficiency and resilience. The methodology consists of three key components: a comprehensive literature review, an in-depth case study analysis, and economic modeling to evaluate the financial impact of cybersecurity investments. The literature review involves a systematic analysis of academic research, government reports, and industry publications to establish a foundational understanding of cybersecurity hardening strategies, digital transformation, and their effects on government operations. This review focuses on identifying key challenges in cybersecurity, evaluating best practices, and exploring how robust security frameworks improve public sector efficiency. It provides a theoretical basis for assessing the economic and operational benefits of proactive cybersecurity measures, guiding the case study selection and subsequent financial analysis. The case study analysis examines five major government-related cyber breaches to illustrate the financial and operational consequences of cyberattacks. The selected cases include the SolarWinds Attack (2020), which exposed vulnerabilities in supply chain security across U.S. federal agencies; the OPM Breach (2015), which compromised 22.1 million security clearance records; a U.S. Voter Data Breach, highlighting risks to

election integrity; and the Costa Rica Government Ransomware Attack (2022), which paralyzed public services and caused significant economic losses. These cases were chosen based on their scale, relevance to government operations, and the financial and reputational damages incurred. The analysis identifies common vulnerabilities, assesses incident response effectiveness, and extracts key lessons to inform best practices for cybersecurity hardening. The economic modeling component synthesizes findings from the literature review and case studies to evaluate the financial impact of cybersecurity investments. It identifies cost patterns across breaches, estimates potential losses that could have been mitigated through proactive security measures, and highlights best practices for maximizing return on investment (ROI). The study leverages risk reduction frameworks and historical breach cost data to assess how cybersecurity spending can lead to long-term cost savings and improved operational stability in government agencies. This study acknowledges certain limitations, including reliance on publicly available data, which may not fully capture remediation costs, classified response strategies, or long-term policy changes following breaches. Additionally, quantifying indirect costs such as reputational harm, erosion of public trust, and political fallout remains complex. However, by triangulating insights from multiple sources, this study provides a comprehensive assessment of cybersecurity's role in strengthening government efficiency and resilience while offering actionable recommendations for policymakers and security professionals.

5. Case Studies and Analysis

5.1. SolarWinds Incident

The SolarWinds hack was a supply chain attack where malicious actors breached the SolarWinds Orion software system (Alkhadra et al., 2021). A supply chain attack exploits weaker points in an organization's network, often through third-party vendors, to gain unauthorized access to systems and data. In this case, over 18,000 SolarWinds customers installed software updates containing malicious code, unknowingly enabling attackers to infiltrate their networks. The attack had a far-reaching impact on government and private organizations alike. According to the White House, nine federal agencies—including the Departments of Homeland Security, State, Treasury, Justice, Energy, and Defense—along with over 100 technology companies, were compromised (Cybersecurity and Infrastructure Security Agency & Federal Bureau of Investigation, 2021). A report by Roll Call estimated that American businesses and government agencies could spend upwards of $100 billion over months to contain and mitigate the damage (Pexton, 2021). The indirect costs compounded the financial toll, with companies losing an average of 11% of their annual revenue. The United States faced the highest financial impact, where companies suffered losses averaging 14% of their annual revenue, compared to 8.6% in the United Kingdom and 9.1% in Singapore (Fortinet, 2021). Beyond monetary losses, the attack tarnished the reputations of affected organizations, increased their operational costs, triggered legal actions and customer refunds, and compromised sensitive data. Moreover, a ProPublica investigation revealed that the U.S. government had spent $2.2 million on a cybersecurity system that, if implemented, might have prevented the SolarWinds attack.(ProPublica, 2021)

5.2. US Office of Personnel Management Incident

The 2015 Office of Personnel Management (OPM) data breach targeted sensitive information contained in Standard Form 86 (SF-86) records, which are used for U.S. government security clearances. This breach exposed critical data retained by OPM, affecting 22.1 million individuals, including federal employees, contractors, and their associates.(Gootman, 2016) OPM reported two separate but related cybersecurity incidents stemming from malicious activity on its network. The breach was traced back to a compromised contractor credential, as revealed by a collaborative investigation by the FBI and the Department of Homeland Security. By 2017, the breach had cost the U.S. government over $1 billion, primarily to provide identity theft protection for affected individuals. Two contracts were signed with ID Experts to address these concerns: the first for $340 million in credit monitoring and identity theft protection services, and the second for up to $416 million in extended services. In 2022, an additional $63 million settlement was reached for individuals who could demonstrate financial hardship caused by the breach (Giaritelli, 2022). This incident highlighted vulnerabilities in the bureaucratic system, which some argue contributed to inadequate protection of proprietary information. Others place the blame on senior leadership for failing to implement necessary security protocols to protect sensitive data. Warnings of such a breach were not unforeseen. According to Boyd, 2015, government auditors had warned the Office of Personnel Management (OPM) and other federal agencies about vulnerabilities in their systems. Security experts had recommended enhancing defenses through encryption and deploying software tools to mitigate risks. Unfortunately, these warnings went unheeded.(Brown, 2019)

5.3. Economic Modeling and Analysis

A comprehensive review of existing literature underscores the critical need for economic frameworks that balance cybersecurity investments with organizational risks and outcomes. The Gordon-Loeb Model has long served as a cornerstone in cybersecurity economics, offering a structured approach to determining optimal spending on security measures (Gordon & Loeb, 2002). However, as technology advances and cyber risks evolve, it is imperative to adapt this model to reflect contemporary challenges. This section explores the Gordon-Loeb Model's insights, integrates findings from IBM's 2024 report on breach costs, and incorporates emerging considerations from research on cyber risk quantification, including the work of Böhme et al., 2018.(Ponemon Institute, 2023)

5.4. The Gordon-Loeb Model: Foundational Insights

The Gordon-Loeb Model provides a mathematical framework to help organizations determine the optimal level of investment in protecting their information assets. It offers several key insights into cybersecurity investment strategies. First, the model highlights the principle of diminishing returns on investment. It suggests that the optimal level of security investment should not exceed 37% of the expected loss from a potential security breach. Investing beyond this threshold often results in diminishing returns, making additional expenditures less effective in mitigating risks. Second, the model emphasizes the importance of focusing on mid-vulnerability information. Protecting high-vulnerability information can demand significant resources, which may not always justify the costs. Similarly, securing low-vulnerability data often provides limited returns on investment. Therefore, the model advises prioritizing information assets with medium vulnerability, where security investments are likely to be most cost-effective. Lastly, the model underscores the need for strategic resource allocation. Organizations are encouraged to categorize their information assets based on their value and susceptibility to breaches, enabling a more rational and efficient distribution of security resources. This framework provides a valuable guide for balancing investment and risk in cybersecurity.

5.5. Adapting the Gordon-Loeb Model to Current Challenges

While the Gordon-Loeb Model provides a solid theoretical foundation, adapting its principles to today's dynamic cyber threat landscape involves addressing key developments. Insights from IBM's 2024 report highlight several pressing issues. The global average cost of a data breach has surged to $4.88 million, marking a 10% increase over the previous year and emphasizing the financial stakes of inadequate cybersecurity measures. Additionally, organizations that leverage security AI and automation can save an average of $2.22 million per breach, demonstrating the return on investment in technologies like AI-driven threat detection, encryption, and endpoint protection. Another growing concern is the proliferation of shadow data, which now plays a role in one-third of breaches. This trend complicates the task of tracking and securing sensitive information, necessitating the implementation of advanced data governance frameworks and visibility tools (IBM, 2024).

Furthermore, public sector entities face distinct cybersecurity challenges due to their responsibility for protecting critical infrastructure and citizen data. High-profile breaches, such as the Office of Personnel Management (OPM) hack, have resulted in substantial direct and indirect costs, highlighting the need for optimal budget allocation (Brown, 2019). Unlike private organizations, governments must also address externalities, including public trust, national security, and economic stability. Meanwhile, cyber risk insurance remains an underutilized tool for managing financial exposure to breaches. Böhme et al., 2018 argue that its adoption is hindered by the lack of actuarial data and the unpredictable nature of emerging threats. They advocate for data-sharing frameworks to improve risk quantification, which would help insurers price policies more effectively and incentivize better security practices. As cyber threats evolve, insurers may also need to collaborate with software vendors to mitigate vulnerabilities proactively, creating a feedback loop that benefits both parties.

Emerging technological paradigms further complicate cyber risk modeling. The rise of distributed ledger technologies, such as blockchain, introduces new risks that require novel analytical approaches. These systems rely on cryptographically enforced rules and autonomous algorithms, posing unique challenges for cybersecurity. Moreover, broader trends like the Internet of Things (IoT) and the Fourth Industrial Revolution underscore the necessity for dynamic, predictive models capable of addressing interconnected risks. Adapting

the Gordon-Loeb Model to these realities will require a more nuanced approach that integrates evolving technological, economic, and policy considerations. Leveraging Gordon-Loeb's research, we have modeled the optimal cybersecurity investment based on the average annual cost of a data breach in 2. This investment is projected to reduce the risk of a data breach by 26%, potentially saving organizations millions of dollars per incident (Accenture, 2023).

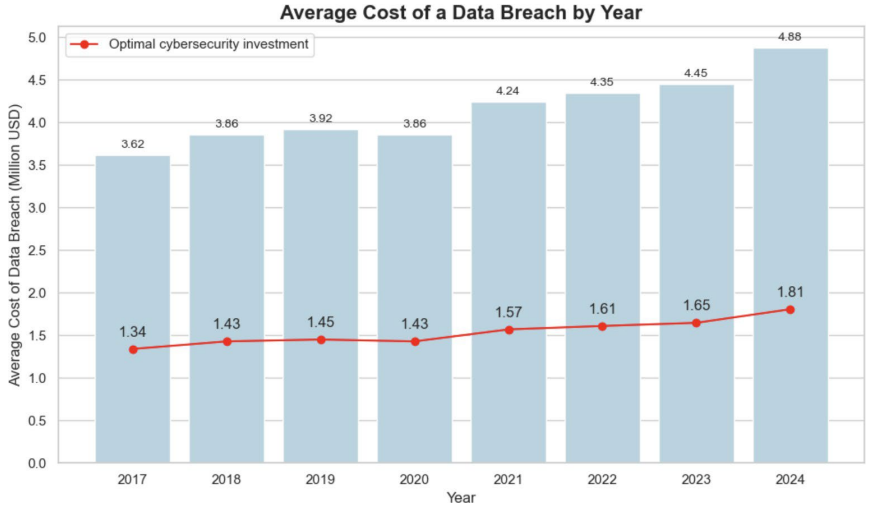

Fig. 2 – Yearly average data breach cost and recommended cybersecurity spending. Data sourced from IBM.

Analyzing the SolarWinds and OPM data breaches through the Gordon-Loeb model demonstrates the importance of optimizing security investments to address vulnerabilities effectively. In both cases, proactive spending on cybersecurity measures—such as robust identity verification systems, privileged access management (PAM) solutions, and AI-driven threat detection—could have mitigated vulnerabilities and reduced overall costs. The model's principle that security investments should be proportional to potential losses and risk levels underscores the need for strategic allocation of resources to areas with the highest impact. An equally critical component of risk mitigation is investing in human capital. Both the SolarWinds and OPM breaches highlight the importance of recruiting skilled security engineers and providing employee training to recognize and respond to potential threats. For example, the average salary of a DevOps Security Engineer in 2025 is approximately $140,000 annually—a cost that pales in comparison to the billions of dollars in direct and indirect costs resulting from these breaches. Organizations should aim to have at least one dedicated security engineer per development team, with larger enterprises requiring a centralized, specialized security team to oversee and manage the overall security posture. Finally, adopting advanced security technologies, such as endpoint protection, encryption, and AI-enabled threat detection systems, combined with a disciplined approach to patch management, is essential to reducing vulnerabilities. Although these measures involve significant upfront costs, they provide a high return on investment by reducing risk exposure and strengthening organizational resilience. By leveraging economic models like Gordon-Loeb and implementing smarter spending strategies, organizations can mitigate the likelihood and impact of future breaches, turning cybersecurity investments into a long-term safeguard for operational and financial stability.

5.6. Application to Government Efficiency

By integrating insights from the Gordon-Loeb Model and Böhme et al.'s research, governments can enhance cybersecurity investments in ways that align with their broader goals of efficiency and resilience. Strategic investments in AI, automation, and encryption can significantly reduce breach costs. Proactive measures to manage shadow data can mitigate risks stemming from poor data governance. According to Gordon and Loeb, the optimal level of security investment (S) should not exceed 37% of the expected loss (L) from a breach, expressed mathematically as $S \leq 0.37 \times L$, which helps avoid over-investment while addressing critical vulnerabilities (Gordon & Loeb, 2002). Governments can use data-sharing frameworks to assess risk at both individual and systemic levels, improving decision-making. The shortage of skilled cybersecurity professionals presents a significant challenge to maintaining secure systems, so investing in training programs for existing employees and recruiting specialized security engineers can dramatically improve an organization's ability to detect and mitigate threats. By employing Security Operations (SecOps) teams equipped with advanced tools

and knowledge, governments can enhance real-time threat monitoring and incident response capabilities. Training initiatives can also extend to non-technical personnel, fostering a culture of cybersecurity awareness and reducing human errors, often a major source of breaches. Cyber insurance can play a pivotal role in promoting security best practices, with premium differentiation, as proposed by Böhme et al., 2018, encouraging organizations to adopt secure-by-design approaches and prioritize risk mitigation throughout the supply chain. Finally, a robust cybersecurity posture fosters trust in digital public services, which is critical for successful digital transformation initiatives The Gordon-Loeb Model offers a robust framework for optimizing cybersecurity investments, and its relevance has become increasingly critical in the context of rising breach costs, and the rapid evolution of technological landscapes. As demonstrated in the research, organizations and governments can adopt a more comprehensive approach to managing cyber risks by balancing investments with expected losses, embracing cutting-edge technologies such as AI, automation, and Privileged Access Management (PAM) solutions, investing in human capital through the recruitment of skilled security professionals and employee training programs, and leveraging cyber insurance to incentivize better practices and mitigate risk exposure. By integrating economic models such as the Gordon-Loeb framework with predictive analytics, dynamic risk assessments, and a forward-thinking approach to emerging threats, organizations can enhance their resilience, ensuring their ability to navigate the complexities of a rapidly advancing digital landscape.

6. Strategies for Cybersecurity Hardening

Governments must adopt a multi-pronged approach to harden cybersecurity systems, especially as threats grow in sophistication and impact. Strategic investments, technical controls, workforce development, and public-private partnerships all play critical roles in strengthening national cybersecurity postures. Strategic investments in cybersecurity are often shaped by economic constraints, policy priorities, and perceived risks. Governments tend to increase funding when the cost of inaction—such as fallout from major cyberattacks—surpasses the cost of implementation. High-impact events like ransomware incidents or geopolitical tensions prompt accelerated adoption of Zero Trust Architectures (ZTA), Endpoint Detection and Response (EDR), and AI-powered threat intelligence platforms. Frameworks like NIST CSF, FedRAMP, and ISO 27001 promote investment by enforcing compliance, while partnerships with the private sector offer access to funding and technical expertise (Cybersecurity and Infrastructure Security Agency, 2023; National Institute of Standards and Technology, 2022).

On the technical front, scalable defenses are necessary to safeguard sensitive government systems against nation-state actors and cybercriminals. Following the SolarWinds attack, U.S. agencies prioritized ZTA, which enforces continuous verification through identity and access management (IAM), micro-segmentation, multi-factor authentication (MFA), and conditional access policies (Alkhadra et al., 2021; Cybersecurity and Infrastructure Security Agency, 2023). Broader deployment of EDR, mobile device management (MDM), and automated threat intelligence tools enhances detection while balancing operational efficiency (National Institute of Standards and Technology, 2022).

Given that human error remains a leading cause of breaches, workforce training and cyber hygiene are essential. However, enforcing best practices across large public institutions can be challenging. Integrating mandatory cybersecurity training, gamified learning, and phishing simulations boosts employee engagement and adoption (European Union Agency for Cybersecurity, 2023; Ogundare, 2024). Practices like strong password policies, MFA, secure access management, and automated patching reduce exploitable vulnerabilities (National Institute of Standards and Technology, 2022). Regular audits and assessments help evaluate the effectiveness of these initiatives and ensure compliance.

Finally, public-private partnerships are vital for accessing cutting-edge technologies and real-time threat intelligence. Collaborations with cybersecurity vendors, ISACs, and CISA's Joint Cyber Defense Collaborative (JCDC) support proactive threat mitigation and rapid incident response (Cybersecurity and Infrastructure Security Agency, 2023). Joint cyber exercises improve crisis coordination and expose vulnerabilities in existing systems. Academic partnerships also contribute to workforce development by advancing research and specialized training.

By integrating strategic investments, technical defenses, workforce preparedness, and cross-sector collaboration, governments can enhance resilience, minimize disruptions, and respond more effectively to the evolving cybersecurity threat landscape.

7. Discussion

7.1. Benefits of Cyber Security Hardening

Improved Service Reliability: Secure systems play a pivotal role in ensuring the uninterrupted availability of critical services, ranging from emergency response systems to welfare distribution networks. For instance, a study by Zhani et al., 2021 highlights that robust cybersecurity measures significantly reduce the downtime of essential services during cyberattacks, ensuring operational continuity even under duress. This reliability not only minimizes disruptions but also builds public confidence in digital governance frameworks. Furthermore, high service reliability mitigates the ripple effects of service outages, such as economic losses and reputational damage, thereby stabilizing broader societal systems reliant on these services.

Cost Savings: Preventing cyber incidents reduces the financial burden of remediation, legal liabilities, and lost productivity. Investments in cybersecurity yield substantial financial benefits by preempting the high costs associated with cyber incidents. According to Ponemon Institute's 2023 Cost of a Data Breach Report, organizations with advanced security frameworks reported an average cost reduction of 28% per breach compared to those with minimal defenses (Ponemon Institute, 2023). This cost efficiency is achieved through reduced expenditures on incident remediation, legal liabilities, regulatory fines, and the indirect costs of lost productivity. Moreover, proactive measures such as network segmentation and endpoint security can significantly decrease the financial impact of potential threats, transforming cybersecurity from a cost center to a strategic investment with measurable returns (Böhme & Schwartz, 2022).

Enhanced Public Trust: A strong cybersecurity posture not only protects sensitive information but also fosters public trust in digital systems. Citizens are more likely to engage with government-led technological initiatives, such as e-voting platforms or digital health records, when assured of their data's safety. Research by Smith and Duggan, 2020 reveals that public trust in digital services increases by 45% when organizations visibly demonstrate adherence to cybersecurity best practices. Additionally, transparent communication about security measures and regular audits can reinforce this trust, creating a virtuous cycle of increased adoption and innovation in public service delivery.

Strategic Advantage: Cybersecurity hardening equips organizations and governments with a proactive approach to risk management, enabling them to allocate resources toward innovation rather than crisis mitigation. As noted by Johnson et al., 2022, governments that prioritize cybersecurity are better positioned to leverage emerging technologies, such as artificial intelligence and blockchain, without the fear of compromising system integrity. This strategic advantage not only enhances operational efficiency but also bolsters national security by preempting cyber threats. Furthermore, strong cybersecurity frameworks provide a competitive edge in the global arena, as they attract international investments and partnerships by demonstrating robust risk management capabilities.

7.2. Challenges

Budget Constraints: Implementing comprehensive cybersecurity measures demands substantial financial resources, which can be a significant hurdle, particularly for developing nations. Many governments face competing priorities, such as healthcare, education, and infrastructure, making it difficult to allocate sufficient funds for cybersecurity. The high costs of acquiring advanced security technologies, maintaining robust infrastructure, and ensuring continuous monitoring and response capabilities further strain limited budgets. As a result, governments may resort to outdated security systems, increasing their vulnerability to cyber threats. Cost-effective solutions, such as leveraging open-source security tools and fostering public-private partnerships, can help mitigate these financial challenges.

Talent Shortages: The global shortage of skilled cybersecurity professionals remains a pressing issue, making it difficult for governments to build and maintain resilient security systems. A lack of trained personnel can lead to gaps in threat detection, incident response, and overall security posture. Many developing nations struggle with brain drain, where skilled professionals seek higher-paying opportunities in the private sector or abroad (Reuters, 2024). To address this, governments must invest in workforce development initiatives, such as specialized training programs, cybersecurity education in universities, and incentives to retain talent within the public sector. Additionally, collaboration with international organizations and private companies can help bridge the talent gap by providing training and expertise.

Evolving Threats: Cyber threats are constantly evolving, with attackers developing more sophisticated techniques to bypass security measures. Governments must stay ahead of emerging risks, including artificial intelligence-driven attacks, advanced persistent threats (APTs), and zero-day vulnerabilities. One of the most pressing future challenges is the potential impact of quantum computing, which could render current encryption standards obsolete. Proactive investment in quantum-resistant cryptographic solutions and adaptive cybersecurity frameworks will be essential to mitigate this risk. Continuous threat intelligence gathering, regular security audits, and agile policy adjustments are necessary to ensure that security measures remain effective against emerging cyber threats.

Bureaucratic Hurdles: The implementation of cybersecurity measures within government institutions often faces significant bureaucratic challenges. Lengthy procurement processes, rigid administrative structures, and inter-agency coordination difficulties can delay the adoption of critical security solutions (U.S. Government Accountability Office, 2024). Additionally, differing priorities among government departments can lead to fragmented security policies and inconsistent implementation. Overcoming these hurdles requires streamlined governance structures, clear cybersecurity mandates, and enhanced collaboration between agencies (Report of Commission on the National Defense Strategy, 2024). Establishing centralized cybersecurity authorities and implementing clear accountability frameworks can improve decision-making and accelerate the deployment of effective security measures.

7.3. Limitations

The foundation of our economic modeling relies heavily on accurate estimations of data breach costs, which are inherently difficult to measure and can vary significantly. While we have utilized industry-standard reports like IBM's Cost of a Data Breach study, these figures represent averages across diverse organizations and may not perfectly reflect the unique circumstances of government entities. The long-term and indirect costs of breaches, such as reputational damage or loss of public trust, are particularly challenging to quantify accurately.

Furthermore, we propose that investing in cybersecurity might lead to a substantial decrease in risk. Our proposal relies on generalized models, such as the Gordon-Loeb Model, which are built on theoretical assumptions like diminishing returns on security investments and a linear correlation between spending and risk reduction. These assumptions may oversimplify real-world complexities, such as interdependencies between different security measures and organizational processes. The effectiveness of security investments can vary greatly depending on factors such as the quality of implementation and operation, the maturity of existing security measures, and the specific threat landscape faced by an organization. As a result, the actual outcomes of security investments may deviate from our projections.

Overall, cybersecurity is a rapidly evolving field, with new threats, technologies, and defensive strategies emerging continuously. As a result, our research may become outdated over time as novel attack vectors and mitigation techniques reshape the security landscape. Excessive cybersecurity controls can hinder the efficiency and responsiveness of government operations, while too little leaves critical systems vulnerable to attack. Striking the right balance between security and functionality is essential to ensure both resilience and operational success.

Additionally, while we have relied on industry reports and established models, these sources may age quickly, potentially limiting their applicability to future cybersecurity challenges. Continuous updates and reassessments will be necessary to ensure the relevance and accuracy of our findings.

8. Future Directions

The future of cybersecurity will be shaped not just by cutting-edge technologies, but also by how well we collaborate globally and engage everyday people. Artificial intelligence (AI) is already transforming the field by helping detect threats faster, automate responses, and find system vulnerabilities before attackers do. These systems learn over time, getting better at spotting unusual behavior and taking action quickly, which helps security teams focus on big-picture strategy. But while AI makes defense smarter, quantum computing introduces new risks. Encryption methods we rely on today—like RSA and ECC—could be broken by quantum computers in the next couple of decades (Vermeer & Peet, 2020). That's why there's a growing push to

develop quantum-safe alternatives like lattice-based and hash-based algorithms. On the global stage, cyber threats don't stop at borders. International efforts—like the Budapest Convention, the Five Eyes alliance, and INTERPOL's cybercrime programs—are becoming essential for sharing threat intelligence and coordinating response efforts (Council of Europe, 2025; INTERPOL, 2025; Rix, 2023). And beyond governments and tech, people play a key role too. When citizens are educated about digital risks and know how to report suspicious activity, they become part of the solution. Strong cybersecurity in the future will depend not only on smart machines and strong laws but also on an informed and engaged public.

9. Conclusion

Cybersecurity hardening has evolved from a defensive measure to a strategic imperative for modern governance. As governments accelerate their digital transformation, safeguarding critical infrastructure and sensitive data against cyber threats must remain a top priority. Case studies of significant cyber incidents, such as the SolarWinds attack and the OPM breach, highlight the severe financial and operational consequences of insufficient security measures. Despite challenges like budget constraints, talent shortages, and the rapidly changing nature of cyber threats, a proactive, multilayered cybersecurity approach can greatly enhance government efficiency. This paper emphasizes that cybersecurity hardening is not merely a cost, but a vital enabler of innovation and operational effectiveness. Governments that prioritize cybersecurity will be better positioned to harness emerging technologies, optimize resource allocation, and uphold public trust. Looking ahead, international collaboration, workforce development, and investment in quantum-resistant cryptography will be essential to sustaining secure and effective digital governance in an increasingly complex threat landscape. By integrating cybersecurity into the core of governance strategies, nations can protect their digital futures while advancing efficient and secure public administration.

Submitted: 31 January 2025, Revised: 26 March 2025, Accepted: 21 April 2025, Published: 20 May 2025

Abstract. Ensuring organisations are safe from cyber-attacks requires the contribution of every staff member and this also applies to AI risk mitigation. Organisations must assess and implement strategies that ensure AI risk mitigation is not just the responsibility of the cybersecurity team (who are always in short supply), but the entire organisation from the front-line staff who need to classify documents correctly, to the cybersecurity engineers who implement technology solutions to mitigate risks, and top management who drive and implement effective AI strategies, policies and investment prioritisation. In this study, we examine how the distributed digital leadership (DDL) framework can be used to enable agencies across government to mitigate AI risks in the public sector. We conducted semi-structured interviews with cybersecurity practitioners from public sector agencies and determined that AI risk mitigation is indeed everyone's responsibility – spanning people, process, technology and data controls. Using the distributed digital leadership (DDL) framework, we provide actionable suggestions on how collective, and collaborative risk mitigation strategies can be implemented across the public sector by making everyone competent in their respective job role responsibilities. We suggest that a well-aligned DDL can help cushion the skills shortage risks in cybersecurity and the overall management of AI risks in the public service.

Keywords. Cybersecurity, AI risks, Digital Leadership Competencies, Distributed Digital Leadership, All-of-Government.
Research paper, DOI: https://doi.org/10.59490/dgo.2025.957

1. Introduction

The use of Artificial Intelligence (AI) in the public sector has gained momentum over the last couple of years as shown in two recent surveys conducted in the New Zealand public service around the use of AI (DIA, 2025b). The first survey conducted in 2023, was a cross-agency AI survey that focused on the views and uses of AI in the public service. Key takeaways from the survey showed that agencies are increasingly interested in the use of AI, they plan to grow their AI use, knowledge and skills, and they want the benefits that AI provides (efficiency, analysis and service delivery). But they are also concerned about the risks that AI poses including security, privacy and skills shortage (DIA, 2025b). The second survey conducted in 2024 provides an in-depth analysis of how AI is used in the New Zealand public service and the areas of risks that public servants are concerned about. Agencies reported seven areas of risk and barriers for the use of AI in the public service which include: a) skills, capabilities; b) policies, guidance; c) privacy; d) security; e) technical barriers; f) cost, funding; and, g) understanding and support (DIA, 2025b). Similar results were found in other jurisdictions like Canada, the United Kingdom and South Korea where studies of government guidelines for AI use in the public sector have been studied (Beltran et al., 2024). According to Wirtz et al. (2019), the exponential growth of AI has necessitated the need for specialist skills and

competencies to support the implementation of AI in the public sector. Importantly, a common theme that runs through current studies is the lack of AI skills and competencies including in the cybersecurity domain. In addition, the benefits versus risks debate of AI use in the public sector provides paradoxical tensions that are exacerbated by the shortage of cybersecurity talent and competencies across the public sector (Bright et al., 2024; DIA, 2025b). These tensions need to be managed adequately by effective and collaborative AI risk mitigation strategies that will enable the safe use of AI in the public sector.

Managing the tensions requires a new approach that ensures risk mitigation capabilities are embedded in and are contributed from every job/role in the organisation (agency). That way everyone gets to contribute to AI risk mitigation as it is often said 'security is everyone's responsibility'. We argue that by focusing on an All-of-Government (AoG) risk mitigation capability (outcome to be achieved) of the role rather than the number of persons (or skills) that occupy cybersecurity roles, we can achieve better AI risk management outcomes. This means two things: 1) effective risk management as a measurable outcome that is everyone's responsibility, i.e., deliberately and intentionally taking the focus of security risk and mitigation beyond the cybersecurity team, and 2) we must focus on building the skills and competencies in other areas of the business (outside the core cybersecurity team) that contribute to effective AI risk management. For example, data and information management teams should be responsible for developing and enforcing data governance strategies that underpin the use of technology tools in data ecosystems. For example, where technical skills are in short supply, looking more widely across the wider public sector and drawing on the capabilities of different agencies to collectively manage risks that impact the public sector as a whole. Here, if an agency has cybersecurity competencies in AI and has figured out how to safely deploy off-the-shelf AI products, such knowledge can be shared across the sector to benefit agencies without such capabilities. Similarly, effective AI strategies and policies need not be written from scratch by every agency – especially for agencies lacking specialist strategy and policy capabilities. The same can be said of privacy impact assessments, risk assessments, data governance policies, et cetera. These capabilities and artefacts can be shared across the sector, allowing agencies to leverage them within their specific contexts. AI risk management can therefore benefit from an AoG approach underpinned by a distributed digital leadership (DDL) framework, which is the focus of this research. To undertake this, we ask the following research question:

RQ: How can government agencies better manage AI risks across the public sector?

To address this question, we interviewed cybersecurity practitioners in the public sector involved in the day-to-day management of cybersecurity risks in their respective agencies. The rest of this paper is structured as follows. In Section 2 we provide background research covering AI risks and mitigation strategies identified in literature specific to the public sector and in Section 3 we provide a summary of the research methodology. In Section 4 we provide an analysis of our research findings, explaining how DDL can be implemented in Section 5.

2. Background

2.1 AI risks and mitigation strategies in the public sector

Despite the many advantages of using AI, numerous risks abound that may negatively impact the adoption of AI (Beltran et al., 2024) or the realisation of its full potential in the public sector. Knutsen et al. (2024) suggested that implementing AI technologies that are effective and responsibly deployed is a complex undertaking that requires skills and competencies that are in short supply. They also suggested that the benefits and risks of AI are still emerging, making it difficult to manage adequately. Bright et al. (2024) identified some technology risks (e.g. hallucinations, challenges in explainability, and AI bias), economic risks (e.g. dependence on a few corporate organisations for GenAI tools) and the absence of structured skills development programs in AI which may lead to inequities in AI adoption and utilisation. Privacy risks and data leakage are also identified as the unauthorised exposure of personal information or an unintended exposure of sensitive information may negatively impact the adoption of AI tools (Beltran et al., 2024). There is also the issue of technical debt whereby structural redesign challenges and the limited understanding of AI's impact on organisational systems may introduce vulnerabilities or exacerbate existing risks within the technology ecosystem of the organisation (Mergel et al., 2024). Several authors suggest that one of the biggest areas of risk is the lack of skills and competencies in the adoption and management of AI tools in the organisation (Bright et al., 2024; Medaglia et al., 2023; Peretz-Andersson et al., 2021; Persson & Zhang, 2025). This may manifest in the lack of skills for strategizing, leading and governing all types of digital transformation (Valentine, 2016) implementing AI solutions (Mergel et al., 2024), guiding how to appropriately use GenAI tools (Bright et al., 2024), difficulty in integrating AI tools with legacy systems (Persson & Zhang, 2025), over-reliance on private sector expertise (Medaglia et al., 2023) and hesitancy in adopting AI tools (Mergel et al., 2024). The lack of skills and competencies in AI may result in governance, trust and accountability failures for AI systems (Straub et al., 2023) and the ability to adequately identify and mitigate AI risks (Beltran et al., 2024; Knutsen et al., 2024).

In Table 1, we provide a summary of some AI risk mitigation strategies (not an exhaustive list) which shows that skills and competencies in different job roles (not just in cybersecurity) are required to mitigate AI risks.

Tab. 1 – Summary of AI risk mitigations in literature.

Authors	AI risk mitigation strategies
Knutsen et al. (2024)	Enhance cybersecurity programs specific to AI and continuously align AI policy and strategy, learning, collaboration and information sharing.
Bright et al. (2024)	Provide National guidance, training and education, and organisational support, for the use of GenAI. Use open-source solutions like BLOOM to democratise access to GenAI and reduce dependency on large corporations.
Mergel et al. (2024)	Monitor AI privacy concerns, enhance user engagement, and develop an AI maturity framework. Promote peer learning and establish intergovernmental forums to share knowledge about AI implementation.
Beltran et al. (2024)	Ensure adherence to data protection mechanisms and compliance with privacy regulations for AI. Implement cybersecurity standards and risk assessments for AI. Develop explainable AI models and transparency initiatives. Undertake workforce training to develop AI literacy and encourage critical evaluation of AI-generated content.
Medaglia et al. (2023)	Codify ethical AI standards and regulations and monitor their enforcement, fostering data availability and accessibility through centralized data platforms.
Persson and Zhang (2025)	Modernise IT infrastructure to support AI technologies, establish data quality, model independence, adopt ethical frameworks to address societal impacts and prevent bias in AI systems.
Peretz-Andersson et al. (2021)	Foster interdisciplinary research to provide clear definitions and frameworks for AI transformation. Implement top-down and bottom-up strategies for AI transformation, and establish governance frameworks that address responsibility, ethics, and societal communication.

Consistent across these risk mitigation strategies (and as shown in the New Zealand survey), is the need for competencies in AI risk management and mitigation strategies which should include people, process, technology and data controls (Duong et al., 2024) that would enable the successful development and adoption of ethical AI in the public sector (Straub et al., 2023).

People-oriented controls are centred around end users (Duong et al., 2024) and the skills they need (Ferdynandus et al., 2024) to use AI tools effectively. This requires training and education for all management and staff in the organisation centred around security awareness, privacy awareness, AI strategy awareness, et cetera. Risk awareness and mitigation at this level enable the proper classification of data, setting document permissions, management of personal information, et cetera. Process controls ensure that proper business processes and procedures (Duong et al., 2024) have been put in place to mitigate risks and are enforced. For example, ensuring that privacy impact and data assessments are conducted at the start of an AI project implementation rather than at the end and that AI guardrails are identified and implemented from the start. Technology controls relate to the underlying AI technology infrastructure (Ferdynandus et al., 2024), ensuring that technical settings are configured correctly, security and privacy are present by design, AI integrations to legacy systems are managed properly and that security controls are monitored, enforced and operationally effective. Finally, data controls have to do with technical and non-technical controls that govern the use of organisational data. These controls could range from having a holistic data strategy, data governance, data quality enforcement, data loss prevention, data lifecycle management (Duong et al., 2024), et cetera. AI risk mitigation draws on the collective responsibilities and capabilities of data management, privacy, cybersecurity, technology and strategic job roles (Sattlegger & Bharosa, 2024) within the organisation and across the public sector (Knutsen et al., 2024) for effective risk management. In other words, an All-of-government (AoG) approach to AI risk management is required and introduced in the next section.

2.2 AoG approach to cybersecurity risk management

Mature e-government requires both vertical and horizontal integration of information systems across multiple government agencies and departments that provide similar aspects of a shared service to citizens (Layne & Lee, 2001). For example, there can be horizontal integration between government departments that provide social services to citizens which may entail the provision of financial assistance administered by the tax department. This joined-up (all-of-government, or whole-of-government) approach to digital services provides a one-stop-shop for citizens accessing government services through digital channels and enables improved efficiency, enhanced

service delivery (or new service delivery channels e.g., AI) and value creation for citizens. Thus, digital transformation at this stage begins to deliver digital government benefits (Lindgren & Van Veenstra, 2018) because public sector agencies are working together towards a shared goal (Janowski, 2015) – e.g. AI risk mitigation, efficiency gains and cost reduction.

To fully maximise the potential of new digital technologies, public sector agencies need to rethink their institutionalised assets, structures, leadership orientations (job roles accountabilities), skills and competencies because such transformations trigger significant changes that must be properly managed to achieve intended outcomes (Tangi et al., 2021). The alignment of job roles and accountabilities to competencies underpins the success of digital transformation and digital government in the public sector and provides the basis by which leadership competencies can be matched to strategy (Leblanc & Gillies, 2005). In New Zealand for example, the Strategy for a Digital Public Service (NZ SDPS) sets the strategic direction for the digital transformation of the public sector with digital leadership as a key aspect of the strategy. In the strategy, it is stated that digital leadership among other things aims to identify and grow talent at all levels that are diverse and multi-disciplinary, to deliver public sector-wide results – including ensuring cybersecurity resilience and support for government agencies (Adie et al., 2024b; DIA, 2020; Ushaka Adie et al.). Further to the NZ SDPS, is a service modernisation roadmap which is a 3-year programme of customer-focused digital initiatives from across the public sector requiring agencies to implement initiatives that will benefit the public sector as a whole (DIA, 2024b). Again, this reflects the need for more distributed digital leadership in the public sector (Adie et al., 2024a).

2.3 Distributed digital leadership for cybersecurity risk management

We define distributed digital leadership (DDL) as ***the intentional alignment of job-role accountability of digital leaders and the adoption of their shared capabilities for digital government outcomes***. We adopt this working definition as it best describes the DDL framework conceptualised by Adie et al. (2024a) and suggests that this framework can be adapted to support the AoG management of AI risks. This is especially important given the shortage of cybersecurity competencies (DIA, 2025b) in the public sector and the requirement for other job roles to contribute to AI risk mitigation strategies. According to Khisro (2025, p. 1859), "*…AI capability encompasses not only expertise but also various technical and non-technical components [competencies] that are necessary for effectively developing and utilising AI technologies*". The DDL framework demonstrates how both technical and non-technical roles must align (both within an agency and across the public sector) for the effective deployment and mitigation of AI risks in the public sector.

3. Research Methods

We adopted a qualitative research methodology to understand the views of cybersecurity practitioners on AI risks and mitigation strategies in the public sector as they are involved in the day-to-day management of cybersecurity risks (Myers, 1997).

2.1 Data collection

We conducted a semi-structured interview with 21 cybersecurity professionals across four different agencies including the lead agency for digital transformation in the New Zealand public sector. Semi-structured interviews are used when the study would benefit from an open framework and where they can provide more useful insights from a small sample size of interviewees (Pathak & Intratat, 2012). Using semi-structured interviews allowed us to talk about the main themes of AI risks and mitigation strategies, while also allowing the direction of the interview to be shaped by the participant's practical understanding of these (O'Keeffe et al., 2016). We used purposive sampling (Miles Matthew et al., 2020) to recruit our interview participants because we: a) wanted to talk to cybersecurity practitioners involved in the day-to-day management of AI risks in the public sector; and, b) wanted to talk to agencies who are engaging in DDL practice as suggested by Adie et al. (2024a). Those interviewed included three Chief Information Security Officers (CISO), five cybersecurity managers, and thirteen team members comprising cybersecurity architects, analysts and advisors across the four government agencies. We asked these cybersecurity practitioners about their views on the use of AI in government – focusing on AI risk mitigation strategies.

2.2 Data analysis

Interviews were recorded, transcribed and coded into themes using a thematic analysis approach (Braun & Clarke, 2012) similar to (Kumar et al., 2025) beginning with open codes, axial codes (themes) and selective codes (dimensions) relevant to AI risk mitigation strategies. We also provided suggestions on risk mitigation categorisation showing that mitigating strategies span people, process, technology and data controls (Duong et al., 2024). Although not included in our final codes, we highlighted in our discussion section, some of the areas of concern that cybersecurity practitioners have regarding the use of AI in government. Finally, using the DDL framework proposed by Adie et al. (2024a), we provide a practical analysis of how AI risk mitigation strategies can be implemented using the DDL approach. Note that for privacy reasons and given the relatively small cybersecurity

community, the identities of interview participants were anonymised using pseudonyms (see Appendix A).

The DDL framework is underpinned by the following principles. First, everyone in the organisation contributes to the digital transformation outcomes of the organisation (e.g. cybersecurity is everyone's business) with varying job role accountabilities and should be considered digital leaders in their own right. Second, every job role in the organisation requires digital leadership competencies at different levels of expertise depending on job role accountability. Third, for organisational outcomes to be met (e.g. safe use of AI), there must be an intentional alignment of job role accountability of digital leaders and adoption of shared competencies which are the building blocks of capability (McClelland & Boyatzis, 1980; Peppard & Ward, 2004). Finally, given the lack of competencies in niche areas, agencies across the public sector can contribute to and share the collective capabilities across the sector based on each agency's areas of expertise and digital leadership.

4. Findings and Discussions

We categorised AI risk in government into five broad risk areas namely, data risks, privacy risks, data sovereignty and jurisdictional risks, technology risks and AI strategy and adoption risks as shown in Appendix A. Data risks are predominantly around data leakage and exposure of government data through the use of AI tools. A senior cybersecurity architect puts it this way:

> "*There's lots of instances where people have taken their work and put it into a large language model, AI, and said do my job for me, not realising that it's the internet. That thing[data] now is out there for everyone to see. you've just data breached yourself.*" (PCA6).

Privacy risks are associated with privacy breaches and the exposure of personal information to unauthorised parties. Cybersecurity practitioners are concerned that AI tools would make it easier for privacy breaches to occur. Technology risks are associated with the underlying technical infrastructure and mechanisms of how AI works giving rise to bias, hallucinations, or vulnerabilities in AI models. Finally, AI strategy and adoption risks have to do with inadequate leadership and governance oversight of the adoption and implementation of AI tools resulting from a lack of AI strategy, regulation or guardrails. It should be noted that cybersecurity practitioners are also concerned about environmental and sustainability issues with the adoption of AI. Some of these concerns include the cost of adoption of AI for agencies (PCA2) and the environmental impact of vendors' hyperscale data centres that are required to run AI (see LCA2, PCA2, PCA3 in Appendix A). Whilst these concerns are not necessarily cybersecurity risks, if not managed, may impact the adoption or perception of AI in government as Toll et al. (2019) suggested. These risks are mitigated by strategies categorised into four broad areas including AI strategy and policies, AI best practice standards & guidelines, AI risk assessments & security controls and finally, AI awareness & education as shown in Figure 1 below.

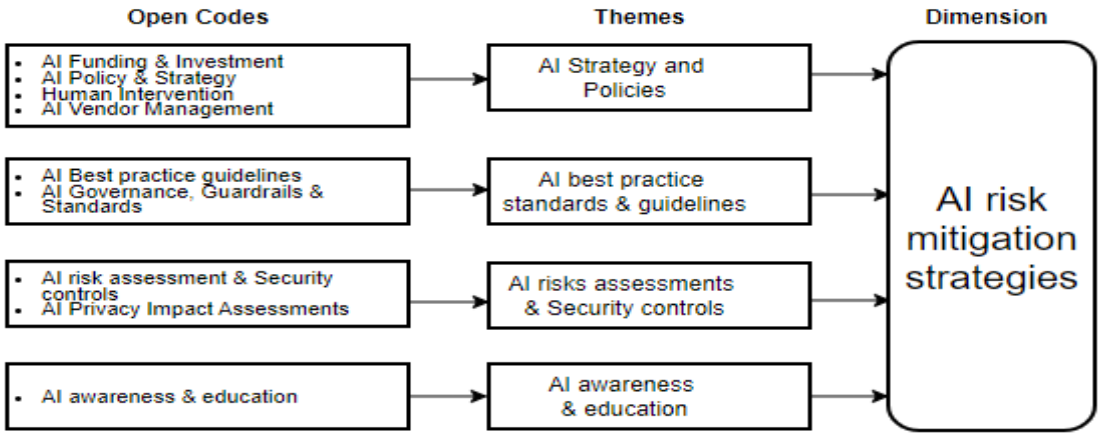

Fig. 1 – AI risk mitigation strategies.

AI strategies and policies primarily relate to people and process (and some governance) controls. They set the stage for how AI is to be used in the organisation and should include requirements for funding and investment, appropriate use, risk management, vendor management and guardrails that must be adhered to. AI strategy and policies need to be socialised, monitored against standards and measures and supported by top management for implementation and adherence to be effective.

AI best practice standards & guidelines touch on process, technology and data controls and are technical documents that are targeted at those tasked with the implementation of AI tools within the organisation. These standards and guidelines could come from technical subject matter experts within the organisation, vendor support documentation or public sector-wide compliance regulations and legislation (Beltran et al., 2024). A cybersecurity practitioner puts it this way "those foundational guardrails really need to be documented or taught about before we go off. Because once you've got those, they can apply to any of those [AI] solutions. [We should be]

prioritizing those guardrails over implementing AI use cases" LCA1. Again, competent monitoring and support are essential.

Conducting AI risk assessments & enforcing security controls is primarily a process control but touches on other areas as risk assessments also involve people, technology and data risks. Risk assessment is probably the most significant AI risk mitigation strategy as signified by the following statements from cybersecurity practitioners – "[conduct] risk assessment, and make sure we have related controls in place which are specific to AI" (LCA5), "the risk appetite of different organisations is quite different" (PCA1), "Do we know what data we are giving away or sharing? Do we know who's going to have access to it?" (PCA7), "Someone needs to monitor and track the AI [tool]. It needs all of those deep level security assessments. regular assessments and regular assurance" (PDT1). Risk assessment for AI should not only be limited to the underlying technology, but it should also cover privacy impact assessments (LDT3, PDT1) and data risk assessment (PCA4) and it should assess the organisational capability and readiness for AI adoption based on their risk appetite and the operational effectiveness of their people, process, technology and data controls.

AI awareness & education are people and process controls that should be tailored to all job roles within the organisation. From general AI awareness programs for all staff to technical training programs provided to those in specialist roles like data management, cybersecurity and architecture. AI training and awareness programs must be determined at the start, needs-based, continuous and updated to keep pace with the ever-changing landscape of the technology (PCA2, PDT2). Some AI vendors offer training and hands-on support in addition to technical documentation and guidelines that can be made available as part of their contractual obligations and vendor support. Microsoft, for example, provide Copilot training programs and technical documentation for the use of Microsoft Copilot in an organisation (Microsoft, 2025d).

These risk mitigation strategies require the deployment of technical and non-technical capabilities (Khisro, 2025) both within an agency and across agency boundaries for public sector-wide AI risk mitigation. However, for DDL to work optimally, the capability of agency leaders to lead, monitor and direct transformation involving AI becomes pivotal (Adie et al., 2024a; Valentine, 2016) as discussed in the next section.

5. Distributed digital leadership approach to AI risk mitigation

Managing cybersecurity risks in the public sector needs a collaborative approach and AI risk mitigation is no different. If cybersecurity is everyone's responsibility – from frontline staff to senior executives - everyone is required to at the very least know how to identify phishing emails and ensure personally identifiable information (PII) is handled according to the agency's privacy policies. Working collaboratively for risk mitigation within the organisation and across the public sector is at the heart of DDL. Cybersecurity practitioners said the following "*It doesn't matter what role you're in, but everyone has been employed because they've got something to bring to the table, so …it is important to be able to work collaboratively to get the best outcome*" (PDT5), "*There is no way that everybody should be an expert and a master in everything*" (LCA2), "*I don't think one person can do it all and I think exactly like you said, a team should play to its strengths and so an organization should play to its strengths*" (PCA5). Whilst specialist cybersecurity, privacy and data management teams ensure that AI risk mitigation strategies are in place and operating effectively, everyone in the organisation contributes to risk mitigation in one way or another. This is shown in Figure 2 which examines common AI risks by type and provides a 2PTD (people, processes, technology and data) approach to mitigation across each risk.

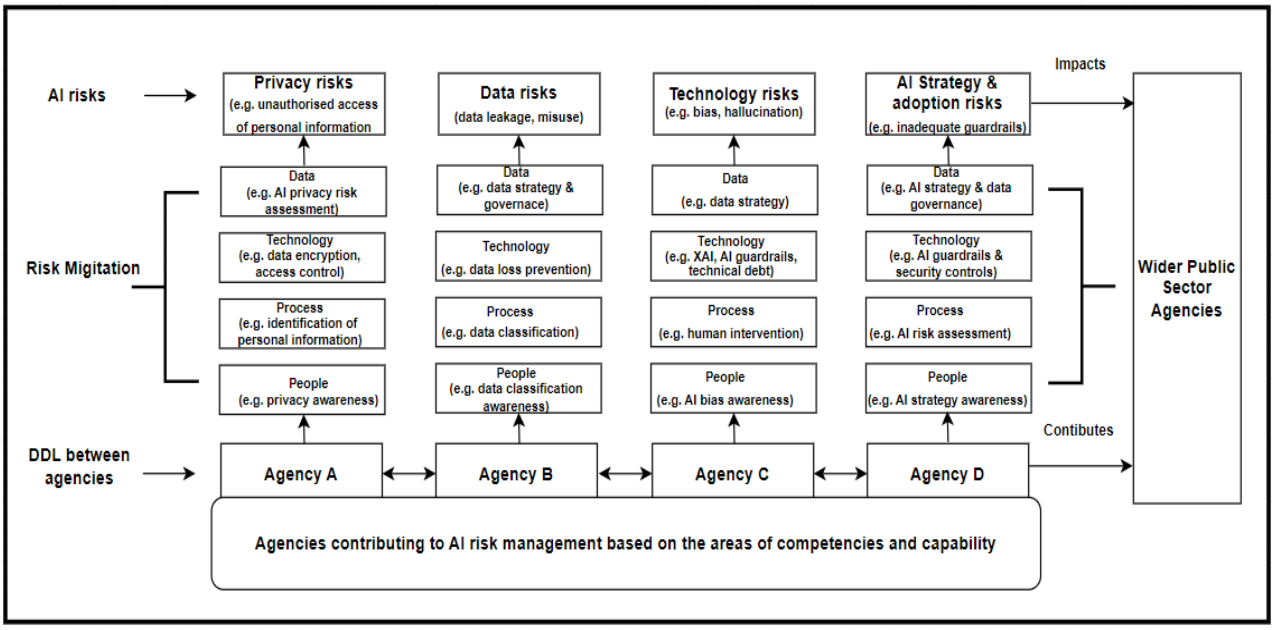

Fig. 2 – Distributed digital leadership approach to AI risk management.

AI risks can be categorised into privacy risks, data risks, technology risks and AI adoption risks. Privacy risks relate to unauthorised access or disclosure of personal information, and these can eventuate when AI agents and models are able to access and surface personal information without prior authorisation and consent. Data risks include data leakage, misuse and exposure of sensitive information especially when effective data governance and access controls are not in place. Technology risks are risks inherent in the use of AI. These risks include AI bias, hallucinations, large language model (LLM) poisoning, et cetera. Finally, AI strategy and adoption risks are risks arising from poor adoption and use of AI in an organisation such as deploying AI without proper understanding of organisational context, use cases and risk mitigation strategies.

As introduced in Section 2, AI risk mitigation strategies must include the 2PTD (people, processes, technology and data) security controls (Duong et al., 2024) with clear roles and responsibilities for job roles across the organisation (Sattlegger & Bharosa, 2024) and the wider public sector – hence a DDL approach. As shown in Figure 2, taking a DDL approach has the potential to positively impact and contribute to improved outcomes across the public sector. There is a many-to-many relationship between risk mitigation controls in the 2PTD framework. For example, AI best practice standards & guidelines are primarily technology controls but are also related to people and processes because technology controls are enforced by technical teams (people) and do require documented processes (process) for continuous improvement and assurance. Similarly, conducting AI risk assessment is a process control but those assessments would usually include people, technology and data risks.

These risk-mitigating controls require capabilities from various teams in the organisation and across the wider public sector to support agencies within the sector, especially smaller agencies that may not have AI risk management capabilities in-house. In Table 2, we provide a summary of how a small sample of different roles contributes to AI risk mitigation using Microsoft Copilot. Microsoft 365 Copilot coordinates large language models (LLMs) which include pre-trained models like Generative Pre-Trained Transformers (GPT-4), integrated into Microsoft 365 productivity apps (e.g. Word, Excel, Teams, et cetera), providing real-time intelligence that enables users to complete tasks more efficiently and enhance their productivity (Microsoft, 2025c). Agencies in the New Zealand public sector that use Microsoft products would most likely have Microsoft 365 Copilot included in the enterprise licenses.

Tab. 2 – Job role contribution to AI risk mitigation using a DDL approach.

Job/role	Contribution to AI risk mitigation	AI risk mitigation strategy
Senior leaders and management teams	Senior management should develop and enforce the implementation of AI strategies, goals, measures of success and governance mechanisms (Valentine, 2016) that govern the use of AI in the organisation including the use of GenAI tools like Microsoft Copilot.	AI strategy and policies. 2PTD: primarily relating to ***people and process*** controls. Example: AI strategy and policies.
Technology, Architecture & Operations	Support the development and enforcement of AI strategy. Ensure alignment with the wider technology and organisational strategies. For Microsoft Copilot,	AI best practice standards & guidelines.

teams	Technology, Architecture & Operations teams should ensure implementation requirements align with organisational technology and AI strategies. Copilot prerequisites, permissions, integrations and guardrails are set up properly (Microsoft, 2025d) and are continuously managed.	2PTD: primarily relating to ***technology*** controls but touches on ***people*** and ***process.*** Example: AI strategy enforcement, AI guardrails, AI configuration, management of technical debt and technology integrations.
Data & Information management teams	Data teams design and govern organisational data strategy that stipulates data governance and management practices including the use of AI. Information management practices should include proper permissions management for sensitive documents, data management lifecycle, enforcement of data owner responsibilities et cetera. For Microsoft Copilot, this would mean ensuring that connections to organisational data sources are done following data governance settings, data risk assessment or regulatory obligations. For example, connections could be prohibited to certain data sources with sensitive or personal information.	AI best practice standards & guidelines. 2PTD: primarily relating to ***data*** controls but touches on ***people process,*** and ***technology.*** Example: Data strategy, data governance, data quality, data loss prevention policies, and data classification.
Cybersecurity teams	Cybersecurity practitioners undertake risk assessments on AI tools and underlying technology risks. They also manage and assess the operational effectiveness of tools that enforce security controls, e.g. access control, data loss prevention, et cetera. For Microsoft Copilot, Cybersecurity would ensure that adequate guardrails (Microsoft, 2025a) are in place (across people, processes, technology and data controls) following organisational risk appetite.	AI risk assessments & security controls. 2PTD: primarily relating to ***process*** controls but touches on ***people, technology and data.*** Example: AI risk assessments and security controls audit.
Privacy teams	Privacy teams undertake privacy impact assessments (PIA) on AI tools and ensure that appropriate controls are in place to mitigate against unauthorised access to personal information. This would mean conducting a PIA for Microsoft Copilot to ensure that access to personal information is done following privacy regulations and organisational requirements (Microsoft, 2025b).	AI (privacy) risk assessments & security controls. 2PTD: primarily relating to ***process*** controls but touches on ***people, technology and data.*** Example: AI privacy impact assessment and enforcement of privacy regulations.
Business analysts	Business analysts document business requirements for AI (Microsoft Copilot), ensuring it aligns with technology and AI strategies. Business Analysts could also help design, document and implement people and process controls including capability and competency analysis as well as establishing strategy-aligned measures of value, uptake and usability.	AI strategy & policies, AI awareness & education. 2PTD: primarily relating to ***people and process*** controls. Example: AI requirements gathering, process controls enforcement, and documentation.
All staff	Understand privacy risks, and data classification for Microsoft Copilot, AI awareness, data strategy, organisational strategy, et cetera. Individual job-role accountabilities are specified and performance standards established,	AI awareness & education. 2PTD: primarily relating to ***people and process*** controls. Example: Privacy awareness, proper data classification, AI bias & strategy awareness.

Every staff member in the organisation should be trained on AI- skills relevant to their job role contribution, with training including AI risks and mitigation strategies to ensure the responsible use of AI tools (Wirtz et al., 2019). As shown in Table 2, AI risk mitigation requires contributions from both technical and non-technical teams within

the organisation with strong oversight from senior leaders and their management teams. Senior leaders' understanding of data and digital transformation is a key digital leadership competence (Ushaka Adie et al.) that should be deployed in the creation of AI strategies that support organisational objectives and minimise risks, and this responsibility should not be left to the IT shop or cybersecurity teams alone.

AI risk mitigation capabilities can also be drawn from the wider public sector. It shouldn't matter what agency AI specialist skills and competencies are located in. Every other agency within the public sector should benefit from the capability they provide, thus, demonstrating DDL at an AoG scale. For example, if Agency A has Privacy Officers with specialist skills in privacy impact assessment for AI tools (e.g. Microsoft Copilot), their knowledge should be shared with the wider sector including artefacts that will enable other agencies on their privacy assessments. Technical teams in agencies that have safely deployed AI tools could share design artefacts or configuration details with other agencies deploying similar AI tools. Security risk assessments could also be shared to enable smaller agencies with no in-house capability to decide on their AI implementation strategy.

Agencies within the public sector can leverage specialist capabilities (across AI strategy, privacy, data, technology, et cetera), create synergies, and support each other to effectively manage AI risks in the public sector. In New Zealand, for example, this is demonstrated in the service modernisation roadmap by the digital leadership of the AoG System Leads for data, digital, procurement, cybersecurity, et cetera (Adie et al., 2024a; DIA, 2024a, 2024b). In the service modernisation roadmap, we find the following examples of how DDL is demonstrated. A) the Government Chief Data Steward (GCDS) leads the initiatives "using data standards more" and the "plan for administrative data pipeline" which both require working with key agencies to identify opportunities for implementing data standards across the sector and developing a plan to build a high-quality administrative data pipeline to provide improved data for service delivery. B) the Government Chief Information Security Officer (GCISO) leads the "Cybersecurity standards", "Cybersecurity guidance" (NCSC, 2025), "Threat and vulnerability management support", and "Secure infrastructure" across government. C) the Government Chief Digital Officer (GCDO) leads the "Government AI search assistant" initiative which involves developing an AI virtual assistant to search across government websites to make it easier for New Zealanders to find the information and services they need. The GCDO also leads the "AoG design system and service design" and "AoG AI work programme" contributing to and supporting agencies to use AI for its benefits while managing the risks (DIA, 2025a). They also lead the "Digital workforce planning" initiative which ensures that the public service can meet current and future service delivery needs. All of these agencies contribute to cybersecurity risk management and AI risk mitigation in the public sector.

We note that our findings and contributions can be applied to jurisdictions with similar public sector structure and democratic settings as New Zealand's, however, where a System Leads approach does not exist, inter-agency knowledge sharing and collaboration should still be encouraged for faster adoption of AI and risk management across the public sector given they all work toward the same outcomes – efficient, trust-worthy service delivery to citizens.

6. Conclusion

There has been a lot of focus on AI risks in the public sector but less on how these risks can be mitigated by leveraging capabilities from different teams within an agency and across the public sector. Our study focused on AI risk mitigation strategies and suggested that Distributed Digital Leadership competencies (Adie et al., 2024a) can be implemented as a risk mitigation strategy especially given and lack of skills and competencies as a risk factor for AI adoption. New technologies like AI provide benefits to the public sector (Bright et al., 2024; Toll et al., 2019) and also risks and barriers (Millan-Vargas et al., 2024) that need to be managed and governed properly (Ganapati & Desouza, 2024). Global Cybersecurity skills shortage (Franco et al., 2024) necessitates a DDL approach to AI risk management in the public sector allowing agencies to share the capabilities (Franco et al., 2024) required for effective risk mitigation of new and emerging technologies.

We have demonstrated that by focusing on the AI strategy, policy and risk management capabilities, agencies and teams (across data, strategy, privacy, business analysis, technology & architecture, et cetera) can contribute to AI risk mitigation based on their job roles accountabilities and capabilities, explaining how DDL is applied within an organisational setting. Also, by leveraging AI risk mitigation capabilities of different job roles both within an agency, and across the sector, government agencies can better manage AI risks across the public sector – thus, addressing our research question.

This study provides two contributions. First, from a theoretical perspective, AI risk management using a DDL approach illustrates the efficacy of AoG approaches to service delivery and technology management across the public sector. Our study emphasises the need for cross-sector collaboration not just for service delivery but for efficiency gains, effective resource utilization (during skills shortages) and for cost savings. Second, from a practical perspective, our study provides practical examples of how distributed digital leadership capabilities across the public sector can be deployed for effective AI risk management. High cost, sustainable implementation of AI,

financial resources and technological capabilities were identified as some of the barriers to the adoption of AI in the public sector (Millan-Vargas et al., 2024). Our study provides practical examples of how capabilities from different job roles across the public sector could be leveraged to address these barriers. A Cybersecurity practitioner captures it this way "*and I do think from a leadership side if we can share competencies across government departments there must be huge savings to be made*" (PDT6). Managing AI risks is indeed everyone's business (responsibility) and distributed digital leadership is one way to operationalise it.

6.1 Limitations and Future Research

Our research showed that DDL can be used to address AI risks and mitigations in the public sector especially as it relates to enabling the distributed deployment of capabilities both within the agency and across the public sector. However, the implementation of DDL may be faced with some challenges such as the lack of annual capability analysis across the public sector, information sharing between agencies and other organisational challenges that need to be addressed which have not been covered in this study. Future research is required to address these challenges and to identify cross-agency factors, processes, and organisational settings that will support the effective implementation of the DDL approach across agencies.

Track 7: Digital Government for Stronger Society

Track Description

Traditionally, digital government research has been focused on improved service delivery, efficient administration, open decision-making, and engaged citizens. The research was mainly driven by problems internal to the government or by relationships between the government and citizens. More recently, the focus has been shifting to dealing with mega-problems like pandemics, war, climate change, migration, etc., that no government has the capacity to handle alone, and to problems of democratic breakup that require balancing government power with societal power. Addressing such problems requires institutions and individuals to work together for the well-being, security, and prosperity of all members of society, thereby building a stronger society grounded in cohesion, solidarity, resilience, equity, inclusion, and other values. This track aimed to examine the evidence for digital government strengthening societies and enabling whole-of-society responses. For example, using digital capabilities to monitor the needs of vulnerable groups, deliver targeted assistance to them, and, in turn, engage them in delivering that assistance to others. The track also aimed to examine evidence that digital government is actually making societies weaker and incapable of a whole-of-society response. For example, using digital capabilities to put groups against each other, e.g., farmers against consumers, to gain their votes, but disabling the prospects for a common climate action.

Abstract. This research investigates the challenges encountered by the National Unity Government (NUG) of Myanmar in delivering digital services amidst the complex socio-political landscape shaped by the 2021 military coup. Employing a sociotechnical framework, the study examines the interplay of technical systems and social dynamics in NUG's initiatives across health, education, and financial services. Digital services such as Telekyanmar, Nway Oo University, and Spring Development Bank are analyzed as transformative tools for governance and public engagement. Despite their potential, these services face critical obstacles, including internet connectivity issues, cybersecurity threats, power shortages, resource constraints, and digital literacy gaps, particularly in rural and conflict-affected regions. The study also highlights the importance of inclusivity, with attention to ethnic and cultural diversity, emphasizing the need for localized solutions and multilingual accessibility. Using mixed-method research, the analysis incorporates in-depth interviews, surveys, and secondary data to capture diverse perspectives from stakeholders, technology experts, and the public. Findings reveal significant adoption barriers stemming from security concerns, trust issues, and lack of infrastructure. Moreover, the public's willingness to engage with NUG's digital services is deeply influenced by their perception of the government's legitimacy, inclusivity, and responsiveness to marginalized communities. The study underscores the importance of building trust and enhancing public access to digital platforms through community-centered approaches, targeted digital literacy initiatives, and robust cybersecurity measures. By addressing these challenges, the research offers actionable policy recommendations to optimize NUG's digital governance. It calls for investment in digital infrastructure, capacity-building programs, and international collaborations to support the sustainability and effectiveness of these services. The findings provide critical insights into how digital governance can serve as a tool for resilience, inclusivity, and legitimacy in the face of authoritarian oppression, advancing the broader goals of democracy and transitional justice in Myanmar.

Keywords. Digital Governance, National Unity Government (NUG), Sociotechnical Framework, Public Service Delivery, Digital Inclusion
Research paper, DOI: https://doi.org/10.59490/dgo.2025.1058

1. Background

Immediately after the military coup in Myanmar, the Committee Representing Pyidaungsu Hluttaw (CRPH) swiftly emerged on February 5, 2021, comprising 17 elected parliament members with a mission to resist the illegitimate seizure of power. Building on the CRPH's mandate, the National Unity Government was formed on April 16, 2021, with 17 ministries to function as a parallel government. At the heart of the NUG's establishment of ministries is the inclusion of public servants and students who participated in the Civil Disobedient Movement (CDM) by integrating CDMers within the bureaucratic system of respective ministries.

These ministries aim to provide alternative governance services in opposition to the State Administration Council's controlled ministries, which aligns with the NUG's overarching objective of running a parallel government. These ministries are currently providing innovative public services in the digital space, as seen in services like Tele Kyan Mar (online clinic services) by the Ministry of Health, Spring Development Bank (online

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

banking service), NUG Pay (money wallet service), and Nway Oo Lottery (lottery service) by the Ministry of Planning, Finance, and Investment, and Myanmar Nway Oo University (alternative education services) by the Ministry of Education. However, as a parallel government, significant challenges and constraints are witnessed while delivering such public services in the digital space. Persistent security threats, resource constraints, public awareness gaps, and fear and concerns about utilizing such digital tools among the public hinder the capacity and effective deployment of NUG's e-services. Hence, in the current situation where SAC-controlled ministries are not providing fair and secure public services, in addition to people's unwillingness to cooperate with SAC's ministries, the public and international community need to understand alternative public services provided by NUG. Therefore, a comprehensive, detailed research report is necessary for the public to clearly understand NUG's services and the challenges and barriers hindering the effective deployment of NUG's digital services.

Innovations that improve service delivery to citizens pointed out the role of government in enhancing service delivery to improve public administration. Government services refer to the activities and functions governments undertake to address the needs of their citizens and improve societal welfare. This can underscore the importance of innovative practices in the public sector that make government operations more efficient and responsive to the needs of the public. By adopting new technologies and simplifying administrative processes, governments can enhance the quality and accessibility of public services, thereby increasing public satisfaction and trust in government institutions. These services are integral to building a healthy relationship between governments and citizens, focusing on transparency, efficiency, and the effective management of public resources. This Study emphasizes that improving government services is not only about enhancing operational efficiency but also about ensuring that these services are citizen-centered, addressing the specific needs and conditions of the population.

Digital government, also known as e-government or virtual government, involves the use of the internet and other information technologies to influence governance. It generally refers to the creation and provision of information and services within the government and between the government and the public, utilizing various information and communication technologies(Fountain JE.,2001). The post-coup political scenario is highly associated with digital arena where digital resistance is central with mobilization for movement and protesting are mostly done through online and on the other hand, the digital oppression is done by the SAC such as tracking, doxxing and misinformation campaigns. While traditional digital government services in other countries are developed either through expanding or accelerating the physical services out of well-structured physical state institutions, NUG and its digital services emerged initially from online without any well-structured physical state institutions.

The NUG has faced criticism for allegedly operating primarily online, which some argue could limit its effectiveness and outreach, especially in regions with poor internet connectivity or in rural areas where digital literacy is lower. This criticism highlights the challenge of providing governance and essential services through digital means alone, particularly in a country with diverse needs and varying levels of infrastructure. While many of the NUG's ministries provide services digitally, several crucial services, especially those related to health, home affairs, defense, and humanitarian efforts, are offered in person, which is vital for reaching all demographics and ensuring inclusivity(Appendix A). The strategic mix of digital and in-person services aims to leverage technology to enhance reach and efficiency while maintaining a physical presence in areas where it is most needed. This balanced approach is especially crucial in regions controlled or influenced by the NUG, where the provision of in-person services helps to cement its legitimacy and effectiveness as a governing body amidst challenging circumstances. According to research limitations, this paper focuses on only three ministries: the Ministry of Health, the Ministry of Planning, Finance, and Investment, and the Ministry of Education, which is currently at the forefront of providing public services in the digital space. The study will use a sociotechnical framework to examine how technological systems interact with Myanmar's current political and social environment. While digital governance in conflict-affected region is increasingly studied, there remains a significant gap in understanding how alternative governance structures like NUG in Myanmar deliver digital public services under authoritarian pressures. This paper addresses these gaps by explicitly examining both the socio-political and technological challenges through a sociotechnical framework.

2. Research Objectives

1. To examine the key digital services and initiatives implemented by the National Unity Government and their contributions to modernizing administrative functions and improving citizen service delivery.
2. To identify the challenges and barriers hindering the adoption and effectiveness of the National Unity Government's digital tools and services.

3. Methodology

This study employed a mixed-method approach integrating qualitative and quantitative data from primary and secondary sources. Primary data collection included semi-structured, in-depth interviews using purposive

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

sampling. Key informants comprised 1-2 representatives from each of the three targeted NUG ministries, selected based on their minimum six months' experience and active involvement in digital public service initiatives. Interviews were conducted both face-to-face in Maesot and Chiang Mai, Thailand, and online, reflecting practical considerations such as accessibility and security constraints. Additionally, two digital technology experts from relevant non-governmental organizations, each possessing at least one year of professional experience, provided specialized insights into technical and operational challenges. An online survey was administered to 100 participants across diverse age groups and geographical locations, aiming to gauge public perceptions and adoption barriers. Respondents were classified into two groups: those familiar and actively engaging with NUG's digital services, and those who were not. Subsequently, three respondents from each category were selected for follow-up interviews to delve deeper into their experiences, concerns, and the factors influencing their engagement with digital services. Secondary data analysis complemented primary data, utilizing reports from NUG ministries, CRPH, NUCC, and relevant academic articles and media sources. The integration of these diverse data sets facilitated a comprehensive analysis, clearly aligning methodological choices with the study's sociotechnical framework and objectives.

4. Understanding e-government and digital service delivery of governments

The evolution of e-government has changed how governments connect with individuals, providing better services and greater transparency. Various terms are used to characterize the phenomenon of government using Information and Communication Technology, such as 'e-governance,' 'online government,' 'one-stop government,' and 'digital government' (Andersen and Henriksen 2006). E-government is more than just a set of tools for citizens to interact with their government; it also changes the production structure, whether in services or information and reshapes communication across institutions. This creates new ways for governments to communicate with the people they serve (Gibreel and Hong, 2017). E-government entails using information technology to improve connections with residents, corporations, and other government entities. Its goals include improving the delivery of government services to residents, boosting communication with business and industry, empowering citizens through information access, and attaining more effective government administration (World Bank 2005, cited by Gibreel and Hong 2017). West (2004) described e-Government as "the delivery of information services online via the Internet or other digital means" (p. 16).E-government is the use of information and communication technologies to improve the delivery of government services, increase efficiency, and promote citizen participation (Heeks, 2006). E-government efforts provide various benefits, including more openness, decreased corruption, better public service delivery, and higher citizen engagement (Bekkers & Homburg, 2007). However, obstacles remain, such as the digital divide, cybersecurity threats, and opposition to change within government institutions (Dawes, 2008). According to Awen, et.al (2013), the definition of e-government is explained accordingly.

The success or failure of digital governance service initiatives can be evaluated through two primary dimensions, the implementation of these systems by government organizations and their subsequent adoption by citizens (Gil-Garcia & Flores-Zúñiga, 2020). Success, in this context, is often defined by the extent to which the digital service in the government system meets its intended objectives within the planned timeframe and budget (Fortune & Peters, 2005). However, the inherent complexity and multifaceted nature of digital service projects make them particularly challenging and susceptible to failure (Glyptis et al., 2020). Digital Services led by government projects are intricate due to their scale, the integration of various technological components, and the need for alignment with existing bureaucratic processes. This complexity introduces significant risks, making these projects prone to failure (Gunawong & Gao, 2017). Indeed, many digital services initiatives by the government fail to achieve their objectives, resulting in the inability to deliver the anticipated benefits (Madsen, Berger, & Phythian, 2014).

Numerous factors contribute to the high failure rate of e-Government projects. These include poor planning and inappropriate implementation, often linked to technical, social, organizational, cultural, and human behavioral aspects (Choi & Chandler, 2020). The United Nations has identified several specific reasons for these failures, such as a lack of understanding of citizens' needs, inadequate infrastructure, ineffective service delivery, lack of stakeholder trust, and issues related to marketing and confidentiality (United Nations, 2008). Additional factors include unclear objectives, failure to engage stakeholders, lack of cost-benefit analysis, and insufficient evaluation mechanisms (United Nations, 2020).The failure of digital government service projects can have several detrimental consequences, including loss of institutional credibility, wasted time and financial resources, increased costs, loss of trust, and persistent resistance to change in future public sector initiatives (Twizeyimana & Andersson, 2019). Heeks (2003) emphasizes that neglecting the environmental, organizational, and social contexts in which e-government systems operate often leads to unrealistic implementations and low acceptance by citizens, further increasing the likelihood of failure. It is important to adopt a comprehensive approach that considers both technical and social dimensions to mitigate these risks. Effective e-government projects require clear objectives, robust planning that ensures the audience feels secure about the direction and management of the project, and active engagement with all stakeholders. Understanding and addressing the specific needs of citizens, ensuring adequate infrastructure, and building trust through transparent and effective service delivery are essential components for success. Furthermore, continuous evaluation and adaptation based on feedback and changing circumstances can enhance the resilience and effectiveness of e-Government systems.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Digital government services are typically classified into four primary categories or dimensions government-to-government (G2G),government-to-citizen (G2C), government-to-employee (G2E), and government-to-business (G2B). Yildiz (2007) expanded this classification by introducing two additional categories: government-to-civil societal organizations (G2CS) and citizen-to-citizen (C2C). According to Joseph (2013), e-Government services are designed and categorized based on the stakeholders or stakeholder groups involved in interactions with the government for whom the particular service is provided. Furthermore, e-Government is often organized according to the level of administration, such as local, state, or federal in some countries, or municipal, county, or regional in others (Joseph, 2013). Governments implementation of digital services is a multifaceted challenge involving the interplay of social, technical, and political dimensions. The NUG, amidst its struggle for legitimacy and control, faces unique challenges in deploying digital services to its citizens.

To comprehensively address the gaps identified above, recent studies highlight additional critical considerations in digital governance during conflict scenarios. Recent literature highlights the critical role digital governance plays in conflict and fragile state contexts, stressing that digital transformation in such environments must consider social, political, and technological dimensions comprehensively (Gunawong & Gao, 2017; Glyptis et al., 2020). Studies by Twizeyimana and Andersson (2019) emphasize how digital governance initiatives can significantly enhance public trust and transparency but also underscore substantial risks, including cybersecurity threats, digital divides, and infrastructure deficits. Comparative research on digital service delivery during political crises further indicates that neglecting stakeholder trust, especially in conflict-affected areas, undermines the success and sustainability of digital services (Choi & Chandler, 2020; Shackelford, 2020). Furthermore, prior studies on digital government failures suggest that common causes include inadequate stakeholder engagement, insufficient infrastructure planning, and limited attention to sociopolitical dynamics (Madsen, Berger, & Phythian, 2014; Dawes, 2008). Additionally, Shackelford (2022) reinforces the need for robust cybersecurity and digital literacy interventions, critical for protecting digital communications in volatile political contexts. This body of literature collectively underlines that effective digital governance, particularly in politically unstable environments like Myanmar, necessitates a balanced sociotechnical approach, explicitly addressing trust, inclusion, infrastructure, and security simultaneously (Damodaran et al., 2005; Hussaini, 2021).

4. Socio-technical framework in e-government or digital services delivery of governments

In the context of digital government services, the socio-technical framework sheds light on the intertwined challenges of implementing digital initiatives. Governments face a balancing act involving technical infrastructure, human agents, and organizational processes, all operating within broader social and political contexts. For instance, the NUG of Myanmar confronts unique challenges in deploying digital services amidst ongoing struggles for legitimacy and control. This highlights the importance of addressing social dimensions like trust, inclusion, and engagement alongside technical innovations (Heeks, 2006; Baek, Kim, & Lee, 2018).Collaborative services, where individuals collectively fulfill unmet needs, illustrate the socio-technical framework in action. When bound by a sense of community, these interactions form a collaborative community, a socio-technical system where social and technical elements mutually reinforce one another in a “virtuous circle” (Trist, 1981; Baek, Kim, & Lee, 2018). For such systems to thrive, planning must encompass data collection, problem diagnosis, and co-design strategies, ensuring solutions are user-centered and culturally responsive (Choi & Chandler, 2020; Joseph, 2013).The socio-technical approach highlights critical challenges in digital governance. Overemphasis on technical elements such as interface design at the expense of social factors like community trust and engagement often leads to suboptimal outcomes (Heeks, 2003; United Nations, 2020). Additionally, human behavior’s variability complicates the design of predictable social interactions, necessitating conditions that foster organic relationship-building rather than attempting to control it (Dawes, 2009).

Despite these hurdles, the socio-technical framework offers significant opportunities. It provides a holistic methodology to evaluate social and technical variables, enabling the creation of sustainable, resilient, and inclusive solutions. For the NUG, this means addressing technical challenges like poor infrastructure and cybersecurity threats while fostering social dimensions such as digital literacy and cultural inclusivity (Goldfinch, 2007; United Nations, 2008). Literature on e-government often prioritizes technological aspects, neglecting the social dimensions critical to successful implementation. The socio-technical paradigm bridges this gap, advocating for a balanced approach where organizational culture, stakeholder engagement, and user behavior are integrated with technology infrastructure (Bostrom & Heinen, 1977). This perspective is essential for developing e-government initiatives that align with citizen needs and governmental goals. For instance, Damodaran et al. (2005, as cited in Hussaini, 2021) stress the importance of combining communication and technological procedures to meet both citizen expectations and local government requirements. Similarly, Hussaini (2021) identifies three key dimensions for e-government implementation environmental (e.g., policies and legislation), organizational (e.g., managerial capabilities and culture), and technological (e.g., readiness and data management) highlighting the need for a socio-technical lens in planning and execution. The socio-technical framework provides a robust foundation for designing e-government services that are resilient, inclusive, and effective. By addressing both social and technical dimensions, governments can create systems that not only meet technical benchmarks but also foster trust, engagement, and sustainability. For the NUG and other governments, embracing this framework

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

means learning from past failures, leveraging holistic methodologies, and navigating the complex interplay of societal, technical, and political factors.

5. The National Unity Government and its digital services delivery

On February 1, 2021, Myanmar's military conducted a coup, deposing the democratically elected government. In reaction, elected MPs and activists founded the National Unity Government in April 2021 to restore democracy and confront the military junta (International Crisis Group, 2021). The NUG has used digital tools to connect with citizens, organise resistance actions, and rally worldwide support. These initiatives adhere to e-government principles by utilising ICTs to improve governance and public involvement in extreme circumstances (Thawnghmung, 2021).The areas of control and influence are classified according to the governing groups that hold power over them. The areas under the major cities are primarily governed by the SAC .These areas typically encompass major urban centers like Yangon and Mandalay and government-based cities like Naypyidaw. In contrast, mixed areas experience a variable level of authority exerted by the SAC, local militias, PDF, and Ethnic Resistance Organizations(EROs), resulting in zones characterized by frequent conflict and instability. The NUG and PDF operating areas refer to the regions where the NUG composed of deposed legislators and their supporters, and their associated defense forces are currently active, for example, Sagaing Region, Magway Region, and some part of Mandalay Region. These areas are not publicly disclosed because of the covert nature of their activities and frequently coincide with EROs controlled area. Areas under the control of the EROs are governed by ethnic groups that have established their own administrative and security systems. The border areas are of utmost importance because of their strategic positioning along Myanmar's borders with neighboring nations. Gaining control over these regions can be exceptionally intricate, as it requires managing a combination of EROs, local PDFs, and Myanmar Military, and occasionally dealing with influences from neighboring states, such as Chin State-Mizoram/India,Karen/Kareni/Mon/Eastern Shan -Thailand, Northern Shan/Kachin- China.(Appendix - B) These regions are crucial due to factors such as trade and migration and are often characterized by security difficulties.

The NUG's usage of social media and encrypted communication platforms highlights the socio-technical concept of collaborative optimisation. These platforms have helped mobilise protesters, disseminate information, and coordinate operations across disparate networks (Gerbaudo, 2018).A socio-technical perspective emphasises the importance of comprehensive cybersecurity measures. The military dictatorship has targeted the NUG with cyber-attacks and monitoring, emphasising the necessity of securing digital communications and protecting critical information. This entails not just adopting technical solutions but also educating people on cyber hygiene and safe online behaviour. The digital gap presents a serious obstacle to the NUG's e-government projects. Access to technology varies greatly throughout Myanmar, with rural and marginalised people frequently missing dependable internet access (World Bank, 2021). To promote inclusive participation, the NUG address these discrepancies through digital literacy initiatives and measures to increase internet access. Before the coup, Myanmar was making progress towards e-government services. The government initiated a number of projects to digitise public services, improve internet infrastructure, and increase digital literacy among residents (UNDP Myanmar 2020). The emphasis was on promoting transparency, decreasing corruption, and improving public service delivery through digital means.

The 2021 coup drastically slowed Myanmar's progress towards a digital government. The SAC shut down the internet, limited access to social media platforms, and tightened surveillance of digital communications (Access Now, 2021). These policies hampered the NUG's and other pro-democracy organizational capacities to rally support and coordinate resistance efforts. The NUG has been able to keep its operations and communication channels running by utilising cloud-based technologies and decentralised networks. In order to gain foreign support, the NUG has created online platforms for citizen involvement, digital fundraising campaigns, and virtual diplomacy activities (Thawnghmung, 2021).To address the issues of the digital divide, efforts must be taken to improve Myanmar's digital infrastructure. This involves increasing broadband access, enhancing internet reliability, and providing affordable connectivity to all individuals. International relationships and investments can help achieve these objectives (World Bank, 2021). Digital literacy is required for effective citizen engagement in e-government efforts. Programmes targeted at developing digital skills, particularly in rural and marginalised populations, can empower residents to engage with digital government services and participate in the democratic process (UNDP Myanmar, 2020). The NUG and Myanmar's digital government projects continue to prioritise cybersecurity. Implementing strong cybersecurity procedures, cultivating a cyber-aware culture, and working with international specialists can all help to reduce cyber attacks and secure important information (Shackelford, 2022). The NUG's dependence on digital tools to support its governance and resistance operations exemplifies the actual use of e-government ideas in a crisis situation. By taking a socio-technical perspective, the NUG can optimize its digital strategy to improve public involvement, ensure cybersecurity, and bridge the digital gap. Future study should continue to investigate these patterns, particularly in circumstances of political instability.

5.1 NUG Ministry of Education's Efforts in Providing Alternative Education Services in Digital Way

Despite operational limitations, the Ministry of Education of the NUG continues to offer sustainable alternative education services to support students participating in the CDM. The NUG's interim educational services can be primarily divided into two categories: digital education and on-ground education, both of which are often interconnected. The enrollment of students in these services is largely dependent on their access to the internet

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

and the security situation in their respective areas. Regarding on-ground education, it has been reported that more than four thousand schools have been established in liberated areas, providing in-person learning opportunities. While the SAC education system operates in major cities, the NUG's education system is active in liberated zones. It would be inaccurate to claim that students in urban areas are exclusively enrolled in SAC-affiliated schools and universities. At the outset of the Spring Revolution, SAC's education system was significantly disrupted by a large-scale CDM movement, leading to the establishment of interim education providers under the NUG and the development of alternative education systems. Many students in major cities, particularly at the higher education level, have actively resisted the education system of SAC by joining the CDM and enrolling in institutions affiliated with the NUG or other independent educational entities providing alternative services. The NUG's MoE offers education services across basic education, higher education, and vocational training. For basic education, schools in liberated and ethnic areas are providing in-person learning, while digital education services via online schools are also crucial for ensuring continuous access to education. The MoE oversees currently oversees sixty five online schools, which must be officially recognized and comply with the Ministry's information and technology security guidelines. These online schools offer education from kindergarten (KG) to grade 12, with curricula tailored to different regions of the country.

Admissions to NUG educational programs are carefully managed according to security protocols. Guardians or students can initiate contact via social media platforms, where they are required to submit documentation verifying their participation in the CDM. This verification process involves a recommendation letter from a CDM teacher, university, or student council. Students must also complete an admission form, and the Ministry provides video tutorials for each step, including how to anonymize identities and avoid sharing sensitive personal information. The curriculum provided by the MoE is designed for home-based learning, though schools have the academic freedom to adopt various curriculums. Some schools utilize non-formal curriculums, social science-focused syllabi, and others in ethnic areas adopt curricula that align with local languages, cultures, and political contexts. Many schools follow the curriculum recommendations of the NUG, which emphasize the development of good citizenship and respect for diversity. This decentralized and flexible approach to curriculum design contrasts sharply with the centralized, Burmanization-driven curricula of the SAC, which have faced widespread criticism.

The teaching methods in online schools are student-centered and highly innovative, utilizing digital tools. Traditional textbooks have been replaced by digital resources such as videos and animations. For example, in biology lessons, teachers use digital videos to explain concepts like plant growth, encouraging students to engage in hands-on activities such as planting and documenting their progress on a digital platform for teacher evaluation. This innovative, experiential approach contrasts with the rote memorization methods used in SAC's education system. For assessment and certification, students who complete grade 12 can take the Basic Education Completion Assessment (BECA), conducted by the MoE. This certification is essential for further educational or career opportunities. The BECA is conducted online with students required to use their cameras. In 2023, more than 60,000 students participated, with over 50,000 passing, though some faced challenges due to technical issues and instances of fraud(Interview with Headmaster of Myanmar Basic Online School,21 July 2024). For lower-grade assessments, mid-term and year-end exams are primarily conducted via Google Forms, with questions in multiple-choice, fill-in-the-blank, or short-answer formats. As for technical difficulties, exams may be provided in PDF format, and some are administered via Telegram calls. In addition to exams, students are assessed throughout the year through assignments, presentations, and homework submitted via Google Classroom and Google Drive. Student performance is evaluated holistically, factoring in test scores, attendance, participation, and overall conduct, which differs from SAC's system, which is heavily reliant on exam results alone.

The NUG's efforts to provide alternative higher education services are especially significant, as university students have played a central role in the CDM and the Spring Revolution. Student and teacher unions from various universities have established interim councils to offer alternative educational opportunities in collaboration with the MoE. These councils attempt to provide degree and certificate programs across various disciplines. In addition to pre-existing institutions such as arts and science universities, medical colleges, and technical colleges, new institutions affiliated with the NUG have been created. For the 2024-2025 academic year, 59 degree programs from 17 universities will be offered through online platforms, including a Learning Management System.

For assessment and quality assurance, students are required to earn credits by completing assignments, projects, and class participation. For instance, students at Wunzin Online University must submit a thesis under the supervision of their professors to earn credits for graduation. These students also have the opportunity to present their research at international conferences, such as those in the United States, in connection with their university. At vocational institutions like Spring Film Academy, students must complete 12 courses per year, earning 3 credits per course, with a final project, such as producing a film, required for graduation. To complete their studies, students must maintain 75% class attendance and meet credit requirements(Interview with a CDM Professor working at online higher education institution affiliated with the Ministry of Education, National Unity Government of Myanmar, 23 July 2024).To overcome the issue of CDM students' lacking opportunities to proceed to further education by bridging into international universities, the MoE is attempting to link and sign Memorandum of Understandings (MoUs) with international universities. The ministry has successfully signed MoUs with regional and international universities that results in allowing students to continue their education at such institutions. MoE's efforts in overcoming accreditation challenges via providing digital education service fills the gap of lacking further education and employment issues that a majority of youths are facing as a socio-economic issue happened after the post-coup scenarios.

Analyzing the digital education service of NUG through a sociotechnical lens highlights the interplay between technological strategies and socio-political contexts. The NUG's digital and on-ground education systems serve not merely as alternative educational platforms but also as tools of sociopolitical resistance, strengthening resilience amid political instability and security threats. The establishment of decentralized, flexible curricula and student-centered methodologies directly responds to the centralized and authoritarian of SAC education model, promoting academic freedom and educational integrity. Furthermore, digital platforms embody Education 5.0 principles by integrating adult learning methodologies, lifelong learning practices, and home-based education approaches, effectively adapting to Myanmar's diverse socio-cultural contexts. Nevertheless, the effectiveness of these services hinges critically on internet accessibility, digital literacy, and user trust, emphasizing the need to continuously balance technological innovations with social considerations to sustain engagement and legitimacy.

5.2 NUG Ministry of Health's Digital Healthcare Services

Driven by a robust population of healthcare workers participating in the CDM, the Ministry of Health (MoH) of NUG stands out as a pivotal institution in the provision of both digital and on-ground healthcare services. The NUG's Ministry of Health provides four interlinked healthcare services: on-ground, emergency, primary, and online care. Despite security challenges, it operates a structured health system reaching 198 townships (60% of Myanmar), especially in revolutionary-controlled areas. From April 2021 to March 2024, it treated over 1.1 million outpatients, performed 40,169 surgeries, and managed 4,140 referrals. Services are supported by 77 hospitals, 377 clinics, and 250 mobile units. Emergency care and the National Immunization Programme are key in conflict zones, with school health services reaching 962 schools. These efforts reflect the MoH's broad and resilient healthcare delivery. However, due to research limitations, this paper will focus specifically on the ministry's online healthcare services.

Telekyanmar, launched on 19 June 2021 by the NUG's Ministry of Health, is a fully online telemedicine service run by CDM healthcare workers. Accessible via Telegram and Facebook Messenger, it provides remote medical consultations to people in Myanmar and abroad. Patients book appointments through its Facebook page and are directed to general clinics via Telegram. Based on symptoms, they may be referred to one of 25 specialist clinics. Physical exams and diagnostic tests are done locally, with follow-up consultations conducted online. Telekyanmar offers a secure, innovative healthcare alternative amid ongoing conflict and limited physical access.

Telekyanmar has the policy of refusing to handle emergency situations, advising patients to contact local hospitals or clinics. However, in critical situations where patients cannot visit physical clinics, Telekyanmar's doctors provide guidance on how to manage the patient's condition. According to a CDM doctor working at Telekyanmar, most users seek initial discussions to understand their symptoms and receive treatment instructions rather than who would like to get medical services that can completely cure diseases such as surgeries. Following consultations, doctors provide prescriptions for patients to purchase medications at local pharmacies and offer ongoing monitoring and treatment in subsequent sessions (Interview with a CDM doctor working at Telekyanmar, the Ministry of Health, National Unity Government of Myanmar,27 July 2024). In its first year, Telekyanmar served patients from 298 townships in Myanmar, with usage increasing each year, reaching 319 townships in its second year (refer to Fig. 1 below). Over three years, the MoH reported that Telekyanmar provided more than 170,000 free consultations, covering 321 out of 330 townships nationwide and Myanmar citizens from 47 different countries.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Fig. 1 – Map illustrating the reach of Telekyanmar users across 319 townships (highlighted in red) between June 19, 2021, and June 6, 2023.[1]

Telekyanmar provides a "Social Media Service," designed to respond to inquiries submitted by users through its social media platforms. This service is particularly suited for individuals seeking general information about diseases and conditions without requiring a detailed medical consultation. Common inquiries include symptoms, causes, and general treatment recommendations for minor conditions such as allergic reactions, constipation, or swollen eyes, etc. The service is especially beneficial for members of the PDF and internally displaced persons (IDPs) in conflict areas, where access to healthcare facilities is limited. When internet access is available, users in these areas can send questions to Telekyanmar, enabling them to receive essential medical guidance remotely.

Telekyanmar supports mental health through two key services: a Primary Mental Health Clinic and a Psychiatric Clinic, offering general and specialized care. It also runs the "Zero-Suicide Campaign," a hotline addressing psychological distress amid Myanmar's crisis. Inter-ministerial coordination enhances care, with the Ministry of Women, Youth and Children providing counseling for gender-based violence survivors via the "Tine Pin Phaw" program and referring severe cases to Telekyanmar. Patients with chronic illnesses are directed to relevant clinics, and those needing legal aid are referred to the Ministry of Justice's "Mhyata Lan Nyun" platform.

The post-coup socio-political landscape in Myanmar has created an urgent need for accessible and affordable public services, particularly in the healthcare sector. Digital health platforms such as TeleKyanmar have emerged as critical socio-technological interventions. A significant proportion of its users are individuals from economically vulnerable backgrounds, many of whom have been further impoverished by the economic instability induced by the coup. Another key user group includes populations residing in rural and conflict-affected areas, where access to conventional healthcare infrastructure such as hospitals and clinics is severely limited. In addition to physical health, mental health services have become increasingly vital in post-coup, especially for individuals affected by conflict and violence. NUG's digital services have stepped in to fill this gap by offering remote psychological support and counseling. Hence, the delivery of NUG's digital services fulfill the needs of post-coup Myanmar society by using technology as a bridge to these essential services. This socio-technological relevance was further witnessed during the April 2025 high-magnitude earthquake. In the wake of this disaster, the NUG's digital platforms deliver non- emergency healthcare, including mental health support, to victims and rescue workers. This eased pressure on SAC-run hospitals which are already overwhelmed with emergency patients, and showed how technology can bridge service gaps and ease the social needs in crisis.

5.3 NUG's Ministry of Planning, Finance and Investment's Digital Financial Service Delivery

Digital financial services are another remarkable sector of NUG's digital service delivery. Currently, the Spring Development Bank (SDB) and the NUG pay are in service for bringing alternative financial platforms that are decentralized and operating in digital way. These digital financial services are revolutionary and innovative, established to contribute to the Spring Revolution by providing alternative financial services for the general public instead of saving in the banks in Myanmar, which are under the control of the junta back Central Bank of Myanmar. The public's choice to avoid moving funds into the military-based financial system can weaken that system, and hence, NUG's alternative financial services can be termed a "financial war". Moreover, since frequent cases of junta-controlled bank services monitor, track, and freeze the bank accounts of the users, choosing NUG's alternative financial services can provide safety and privacy.

The SDB, established by the NUG's Ministry of Planning, Finance and Investment and licensed by its Interim Central Bank, provides secure digital financial services to support the resistance and enhance financial access in Myanmar's crisis (Mizzima, 2023). Operating entirely online, SDB offers multi-currency transfers, fixed deposits, stablecoin withdrawals, and remittance services via authorized agents globally. Additional services include digital gold savings, e-lottery sales, and decentralized currency exchanges. It also facilitates real estate sales through the "End of Dictatorship" campaign and offers stock shares via Initial Coin Offering (Interview with SDB Executive, 26 July 2024). Complementing SDB, the blockchain-based NUG Pay mobile wallet enables users to save, transfer, and pay in various currencies, helping SMEs transition to a digital economy.

Under the sociotechnical perspective, the widespread adoption of the digital financial services of SDB and NUG Pay underscores a significant shift in public trust and financial behavior in Myanmar. People increasingly prefer these alternative platforms for their perceived security, privacy, and resilience against the SAC surveillance and control, reflecting a collective resistance through financial independence. Furthermore, the blockchain crowdfunding for 2025 April earthquake technology utilized by NUG not only ensures transparency, which is critical in managing humanitarian assistance and contributions to the earthquake and pro-democracy movement, but also enables citizens to contribute without the burdens imposed by traditional financial systems and also aids in protecting citizens from inflationary pressures driven by the military's economic mismanagement. Therefore, these digital financial services embody a dual sociotechnical purpose: empowering citizens economically and reinforcing socio-political resilience through technological innovation.

6. Challenges and Obstacles

Digital governance services under the NUG have emerged as a transformative approach to engaging with citizens, including those in conflict zones, border areas, and internally displaced persons. However, implementing these services is fraught with significant challenges. Due to security concerns, the NUG has largely shifted to online platforms to deliver services, avoiding physical locations that could be vulnerable to military airstrikes and surveillance. Yet, internet connectivity remains a critical obstacle, with widespread shutdowns across 313 townships and limited access in conflict-affected areas such as Sagaing, Magway, and parts of Tanintharyi, where military-controlled providers like Mytel dominate. This not only hinders the provision of digital services like banking, healthcare, and education but also raises concerns about surveillance and privacy. To mitigate these challenges, the NUG has turned to satellite-based internet services like Starlink, enabling connectivity in over 150 areas. However, the high cost of equipment, legality concerns, and inconsistent performance due to limited satellite coverage remain significant barriers. Furthermore, the military's crackdown on alternative connectivity solutions, such as seizing Starlink devices in Thailand, underscores the risks associated with using such technologies.

Myanmar's digital services face major challenges from frequent power outages, especially in cities like Yangon and Mandalay, disrupting device use and digital access. In NUG-controlled areas, reliance on solar panels and generators helps, but rising fuel costs and military fuel restrictions strain infrastructure. Power shortages also hinder basic education more than higher education, which can better adapt to online learning. Additionally, the military's post-coup restrictions blocking social media, VPNs, and surveilling users pose serious cybersecurity risks. NUG platforms like Spring Development Bank are frequent cyberattack targets. Weak digital literacy worsens user vulnerability, highlighting the need for better security measures and user education.

The shortage of skilled IT professionals further complicates the NUG's digital governance efforts. Effective digital transformation relies heavily on technical expertise to ensure secure and sustainable systems, yet Myanmar's digital literacy gap remains a critical barrier. Many public sector workers lack basic digital skills, and the exodus of IT professionals after the coup has significantly depleted the talent pool. Those who remain often work part-time or on a voluntary basis, limiting their capacity to contribute fully to digital governance initiatives. The Ministry of Communications, Information, and Technology (MoCIT) has attempted to fill these gaps by mobilizing volunteers and external technical support. However, the reliance on a small pool of skilled professionals and limited in-house expertise across other ministries underscores the urgent need for capacity-building programs. Long-term sustainability requires structured investments in digital literacy and skills development, alongside efforts to retain and support IT professionals in the face of financial and security challenges.

Security and control challenges are pervasive across digital governance services. The military regime's digital surveillance apparatus includes SIM card registration and mobile banking monitoring, enabling the tracking and targeting of individuals suspected of anti-regime activities. Pro-SAC groups have also weaponized social media

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

platforms like Telegram to dox and expose pro-democracy activists, leading to arrests and detentions. These actions have created an environment of fear, discouraging many citizens from engaging with NUG services out of concern for their privacy and safety. In response, the NUG has implemented cybersecurity protocols and digital safety training, yet the lack of a unified international database and fragmented digital infrastructure limits the effectiveness of these measures. Strengthening cybersecurity frameworks and promoting digital literacy across the population are critical steps in building resilience against these threats.

User adoption and digital literacy are central to the success of NUG's digital services. While platforms like Telekyanmar offer innovative solutions for healthcare delivery, gaps in digital skills and infrastructure hinder their accessibility. Many students and educators in conflict-affected regions face challenges in accessing online education due to the high cost of devices and data, as well as unreliable internet connectivity. In some cases, communities pool resources to purchase shared devices, while students travel long distances to access areas with better connectivity. Similarly, digital financial services like the Spring Development Bank play a crucial role in facilitating secure transactions, but users often struggle with unfamiliar blockchain technology and limited withdrawal options, undermining confidence in these platforms.

Trust and legitimacy are critical for the broader adoption of digital governance services. The NUG's ability to deliver effective and inclusive services is a key factor in establishing its credibility as a governing body. While the NUG has made progress in engaging ethnic minorities and marginalized groups, historical grievances and cultural barriers remain significant obstacles. Efforts to promote inclusivity through translation services and localized solutions, such as Telekyanmar's Chin Tele App, demonstrate the NUG's commitment to addressing these challenges. However, limited infrastructure and frequent displacement in ethnic areas continue to impede service delivery.

Tab. 1 – People Trust on Digital Governance Services.

Survey Aspect	**Percentage / Response**
Efficiency of NUG's Digital Services	65.7% highly trust , 22.9% moderately trust it
User trust on Security Protection of NUG Digital Services	62.9% express high trust, 25.7% moderately trust NUG Digital Services Security Protection
People access to NUG Digital Services	37.1% show moderate access, 37.1% show low access to Digital Governance Services
General Trust in NUG Digital Services	45.7% express moderate trust, 34.3% high trust, 8.6% no trust
Reasons for Non-Use of NUG Digital Services	47.1% cite security issues, 44.3% cite lack of internet access, 4.3% question service quality

These findings suggest that trust in digital governance, particularly in crisis contexts, is contingent on both service quality and accessibility. In Myanmar's conflict-ridden environment, trust is not only a matter of perceived efficiency but also hinges on the capacity of governance structures to ensure secure and equitable access. Analysis of the survey data reveals that users generally have greater confidence in the efficiency and security of the NUG's digital services compared to those who express distrust. In contrast, non-users primarily cite concerns over security, limited internet access, and poor service quality as reasons for not engaging with the services. Additionally, responses indicate an even distribution between moderate and low levels of access to the NUG's digital platforms. These findings suggest that, although there is a significant degree of trust in the NUG's digital initiatives, their long-term success hinges on addressing key practical barriers particularly in terms of security and accessibility which are essential for building and maintaining public trust.

International support plays a vital role in overcoming these challenges. The lack of strong international assistance has limited the NUG's capacity to expand its digital governance initiatives. While some capacity-building programs and training sessions have been offered by international organizations, these efforts remain sporadic and insufficient. Enhanced technical and financial support for internet infrastructure, capacity-building programs, and digital literacy initiatives could significantly strengthen the NUG's digital governance capabilities. Recognizing internet access as a fundamental right and fostering global partnerships would not only address existing gaps but also enhance the resilience and legitimacy of the NUG's efforts to govern effectively in a politically fragmented Myanmar. By addressing these interconnected challenges, the NUG can build a more inclusive and sustainable digital governance system to support the country's transition toward democracy and stability.

7. Conclusion

This research reveals the complex challenges faced by the NUG in implementing digital services within

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Myanmar's volatile socio-political landscape. Utilizing a socio-technical framework, this paper illustrates how technical and social factors interact to influence the success of digital governance initiatives. On the technical side, challenges such as inadequate internet infrastructure, frequent power outages, cybersecurity threats, and a shortage of skilled IT professionals hinder the scalability and accessibility of NUG's services. On the social side, barriers including low digital literacy, trust deficits, and cultural diversity, particularly in ethnic regions, impede user engagement. These challenges are compounded by Myanmar's conflict-ridden environment, where military surveillance and repression create a climate of fear that further discourages the adoption of digital tools. This section synthesizes the findings by explicitly linking the empirical evidence gathered from interviews, surveys, and secondary data with the theoretical components of the sociotechnical framework. Key barriers identified such as trust deficits, infrastructural inadequacies, and security challenges are discussed in direct relation to their impact on service adoption and legitimacy, thereby offering sharper and more coherent conclusions.

Despite these obstacles, the NUG has demonstrated remarkable resilience and innovation in its digital initiatives. Telekyanmar offers critical healthcare services, including mental health support and suicide prevention. Similarly, the Ministry of Education has provided alternative educational opportunities through digital platforms such as the Learning Management System and Moodle. These efforts have enabled students in conflict zones and ethnic areas to access flexible curricula tailored to their cultural and linguistic needs. Financial solutions such as the SDB and NUG Pay highlight the government's commitment to transparency and accountability, fostering trust among users despite the operational risks posed by cyberattacks and military control.

The research highlights how the NUG can strengthen its digital governance by improving internet access, cybersecurity, and digital literacy particularly in marginalized areas. Collaboration with ethnic groups and international partners is key to inclusivity and resource support. Despite security-related research limitations, the study underscores the NUG's progress in using technology to deliver essential services. A clear digital roadmap and transparent donor engagement are crucial to building legitimacy and attracting investment. These findings offer both practical strategies and broader insights into digital governance in conflict settings, showing how innovation can advance democracy and resilience amid crisis.

Abstract. Municipal ombudsman offices face challenges in managing increasing citizen demands and stimulating meaningful participation, despite legal frameworks guaranteeing citizen rights. Crowdsourcing presents a potential avenue to improve the efficiency of the Ombudsman office and the engagement of citizens. This systematic literature review (SLR) investigates the application of crowdsourcing in municipal ombudsman offices, synthesizing existing research to identify best practices, challenges, and research gaps. A comprehensive search of academic databases from 2010 to 2023 initially yielded 1590 papers. Following a rigorous five-stage filtering process, 24 relevant studies were selected for in-depth analysis. The findings reveal a growing trend of utilizing crowdsourcing primarily for feedback collection and complaint management, although its application in direct decision-making processes within ombudsman offices remains limited. While the literature reports benefits such as increased efficiency and faster problem resolution, significant challenges persist. These include digital inequality, which can exclude vulnerable populations; concerns about the credibility of citizen-submitted data; and institutional resistance to adopting new, crowdsourced approaches. This review indicates the need for further research into the long-term impacts of crowdsourcing on citizen empowerment and ombudsman office accountability. The study provides a valuable foundation for researchers and practitioners seeking to leverage crowdsourcing to strengthen municipal ombudsman services and promote citizen participation, emphasizing the importance of addressing these identified challenges to realize the full potential of crowdsourcing in this context.

Keywords. Systematic Literature Review, Ombudsman, Crowdsourcing, E-participation, Electronic Government.
Research paper, DOI: https://doi.org/10.59490/dgo.2025.959

1. Introduction

Municipal ombudsman offices play a crucial role in safeguarding citizen rights and promoting government transparency and accountability (Zahn, Viterbo, et al., 2024). However, these offices often face significant challenges in managing the increasing volume of citizen demands and fostering meaningful participation, despite existing legal frameworks (Quintão, 2016). Crowdsourcing, the practice of obtaining contributions from a large group of people, emerges as a potential strategy to enhance the efficiency of ombudsman offices and engage citizens more effectively (Noh, 2022).

Given the importance of ombudsman offices as communication channels between citizens and the government, the reality is that many face limitations in resources, difficulties in processing large volumes of information, and barriers to promoting broad and representative citizen participation (Zahn, Mourão, et al., 2024).

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

While crowdsourcing has shown potential in various public sector areas, its specific application within the context of Brazilian municipal ombudsman offices remains underexplored, lacking a systematic synthesis of existing knowledge (Bouzguenda et al., 2019).

In recent years, the field of e-Participation has witnessed a growing interest in the systematic exploration of existing knowledge (Boudjelida et al., 2016; Hassan and Hamari, 2019; Simonofski et al., 2017) as well as other fields (da Silva et al., 2022; Pincovsky et al., 2021) through a methodological approach known as Systematic Literature Review (SLR – Kitchenham and Charters, 2007). An SLR study includes identifying, evaluating, and interpreting all research relevant and provides empirical evidence. The main reasons to conduct the SLR are: to summarize the existing evidence, to identify any gaps in current research, and to provide a background to the appropriate position in research activities.

The execution of an SLR within the domain of Computing entails adherence to three fundamental phases: Planning, Conduction, and Reporting (Kitchenham and Charters, 2007). The planning phase includes the identification of the urgency for the review, commissioning thereof, articulation of research inquiries, formulation of a review protocol, and subsequent protocol evaluation. The conducting phase involves activities such as the identification of pertinent research, curation of primary studies, evaluation of study quality, data extraction and monitoring, and the synthesis of acquired information. The reporting phase includes the specification of dissemination mechanisms, formatting of the principal report, and its subsequent evaluation.

The main objective of this SLR is to investigate how crowdsourcing has been applied in municipal ombudsman offices, identifying best practices, key challenges, and existing research gaps. In this way, the outcomes will provide a knowledge base regarding the adoption of tools and technologies based on this paradigm, aiming to comprehend the state-of-the-art and the primary challenges faced by these local governments in implementing crowdsourcing.

The rest of this paper is organized as follows: Section 2 presents the theoretical foundations necessary to understand the remainder of this paper. Section 3 approaches our research methodology to support the execution of this systematic review. Section 4 presents the results of conducting the review, following the established protocol. Section 5 presents our findings aligned to our Research Questions (RQs). Section 6 discusses the findings, explores their implications, and addresses potential limitations. Finally, Section 7 presents the conclusions of this work.

2. Theoretical Background

Citizen participation is a cornerstone of democratic governance, allowing individuals to interact with, engage in, and contribute to government decision-making processes, policy design, and the assessment of public services (Simonofski et al., 2017). Achieving meaningful citizen participation, however, is a complex undertaking, requiring authorities to actively create mechanisms to motivate engagement over diverse social and technological landscapes (Bouzguenda et al., 2019).

The use of information and communication technologies (ICTs) to improve public service delivery and promote citizen participation (Polovchenko, 2019), offers a potential pathway to support this interaction and the digital transformation. Through digital platforms, online forums, and mobile applications, e-government aims to make public administration more efficient, transparent, accessible, and responsive to citizens' needs (Grönlund, 2004; Relyea, 2002). E-participation, a key component of e-government, specifically focuses on leveraging technology to facilitate citizen involvement in decision-making and governance (Boudjelida et al., 2016; Hassan and Hamari, 2019; Simonofski et al., 2017).

Within this context, ombudsman offices play a crucial role as intermediaries between citizens and government. Originating in Sweden in 1809, the ombudsman concept centers on an independent official tasked with investigating citizen complaints against government actions and promoting administrative accountability (Batalli, 2015). In Brazil, for example, the term *"Ouvidoria"* is commonly used to refer to institutions that handle citizen feedback and complaints within specific organizations, particularly in the public sector (Comparato, 2005; Quintão, 2016). Municipal ombudsman offices, therefore, serve as vital institutional mechanisms for facilitating citizen participation at the local level, promoting social and political inclusion, and mediating conflicts between citizens and the municipal administration (Antero, 2014). The *"Ouvidor"* (the public official respon-

sible for the *Ouvidoria*), acts as a conduit for citizen voices, receiving and processing demands, and facilitating their resolution by the relevant authorities (Alizadeh et al., 2019; Polovchenko, 2019; Simonofski et al., 2019).

Crowdsourcing, a term coined by Howe et al., 2006, represents a significant development in leveraging collective intelligence to address various challenges. It involves outsourcing a task traditionally performed by employees to a large, undefined network of people through an open call (Estellés-Arolas and González-Ladrón-de-Guevara, 2012). Citizen-sourcing, a specific application of crowdsourcing within the public sector, harnesses the knowledge, skills, and experiences of citizens to improve government services and decision-making (Grossman et al., 2018; Hammon and Hippner, 2012). Estellés-Arolas and González-Ladrón-de-Guevara, 2012 identified eight fundamental elements of crowdsourcing: a clearly defined group, a task with a clear goal, a specified reward for the group, a clearly identified crowdsourcing initiator, compensation for the group, an online and participatory process, an open call of variable reach, and the involvement of the Internet. Crowdsourcing projects can be classified based on various criteria, including the type of task (e.g., crowdcasting, crowdcollaboration, crowdcontent, crowdfunding, crowdopinion) and the initiator of the project (public institutions, citizens, or companies – Garrigos-Simon et al., 2015; Sánchez et al., 2015). This diverse range of approaches illustrates the adaptability of crowdsourcing to different contexts and objectives.

3. Research Methodology

This Systematic Literature Review (SLR) adheres to the guidelines proposed by Kitchenham and Charters Kitchenham and Charters, 2007 to ensure a rigorous, transparent, and replicable research process. The methodology is structured around a detailed review protocol, developed a priori, which guides the three main phases: Planning, Conducting, and Reporting.

The planning phase begins with the identification of the need for a review, justifying its relevance by suggesting a gap in the existing literature or a lack of consolidated knowledge. This is followed by the formulation of precise Research Questions (RQs), structured using frameworks such as PICO (Population, Intervention, Comparison, Outcome) where appropriate, to define the scope of the investigation. The core of the planning phase is the development of the review protocol itself. This protocol specifies the research questions, the comprehensive search strategy (including database selection, search term development, search string construction, and search limits), the study selection criteria (inclusion and exclusion criteria for title/abstract and full-text screening), the quality assessment procedures (using standardized checklists or tools), the data extraction strategy (using a generic form), and the data synthesis methods (narrative synthesis, thematic analysis, or meta-analysis, as appropriate).

The conducting phase implements the protocol. A systematic search is performed across relevant electronic databases using the predefined search strings and limits. Study selection proceeds in stages, typically involving title and abstract screening followed by full-text screening, with independent reviewers at each stage and mechanisms for resolving disagreements. Included studies undergo quality assessment to evaluate their methodological rigor and potential for bias. Data extraction systematically collects key information from each study using the predefined data extraction form. Finally, data synthesis integrates the findings, identifying patterns, themes, and relationships to answer the research questions.

The reporting phase, detailed in the subsequent sections of this paper, disseminates the findings in a clear, comprehensive, and transparent manner, following the structure recommended by the guidelines. This structured approach ensures that the SLR is conducted systematically and that the conclusions are based on a thorough and unbiased assessment of the available evidence.

3.1. Research Goal and Questions

Grounded in the Goal-Question-Metric (GQM) paradigm (Basili et al., 1994), this research aims to analyze scientific publications on crowdsourcing in municipal ombudsman offices. The goal is to identify and characterize the mechanisms (processes, methods, tools, and frameworks) used to enhance citizen participation through crowdsourcing. This analysis is conducted from the perspective of researchers and aims to provide insights relevant to both academia and public administration. To achieve this goal, the following RQs were formulated:

RQ 1. What types of crowdsourcing and citizen-sourcing approaches are employed in municipal ombudsman offices? This inquiry aims to identify and categorize specific crowdsourcing methodologies employed, transcending the mere listing of "techniques".

RQ 2. How have crowdsourcing and citizen-sourcing been applied to enhance citizen participation and engagement in municipal ombudsman offices, and what are the key processes involved? This question goes beyond simply asking if crowdsourcing has been applied. It aims to understand the specific applications and processes used to enhance participation and engagement.

RQ 3. What are the reported benefits and drawbacks of using crowdsourcing and citizen-sourcing in municipal ombudsman offices? This question seeks to identify both the positive and negative outcomes associated with crowdsourcing in this context. It's crucial to consider not only benefits (e.g., increased efficiency, improved transparency) but also potential drawbacks (e.g., unequal access, biased participation, data quality issues).

RQ 4. What are the main limitations, challenges, and ethical considerations associated with the use of crowdsourcing and citizen-sourcing in municipal ombudsman offices? This question expands on the previous one by explicitly focusing on the challenges and ethical considerations. This includes issues such as digital inclusion, data privacy, security, representativeness of participants, and potential for manipulation or misuse of crowdsourced data.

RQ 5. What methodological approaches and evaluation metrics are employed in assessing the use of crowdsourcing and citizen-sourcing in municipal ombudsman offices? This question focuses on how the impacts of crowdsourcing are being measured and evaluated. It's important to understand not only what the outcomes are, but also how researchers are determining those outcomes (e.g., surveys, case studies, quantitative analysis of platform data). Adding "evaluation metrics" clarifies that we are looking for the specific measures used.

By addressing these questions, this review aims to synthesize current knowledge, identify key trends, challenges, and best practices, and ultimately contribute to a deeper understanding of how crowdsourcing can be effectively leveraged to enhance citizen participation and improve public service delivery in this context. The following section details the methodology employed to answer these research questions.

3.2. Search String

To design the search string, we used PICO (Population, Intervention, Comparison, and Outcomes) criteria as described in Kitchenham and Charters, 2007. The elements are as follows:

- **Population**: Ombudsman;
- **Intervention**: Crowdsourcing, citizen-sourcing, and related concepts (e.g., e-participation, collaborative systems);
- **Comparison**: No specific comparison was defined, as the focus is on describing and analyzing existing approaches rather than comparing specific interventions;
- **Outcome**: A broad range of outcomes was considered, including but not limited to: efficiency, citizen engagement, service quality, transparency, accountability, and the development of frameworks or models;

Based on these PICO elements, a comprehensive search string was constructed using a combination of keywords, synonyms, and related terms. Wildcards and truncation were used where appropriate to broaden the search and capture variations in terminology. The search string was designed to be sensitive (capturing a high proportion of relevant studies) while also striving for reasonable precision (avoiding an excessive number of irrelevant studies).

The search string was applied to the title, abstract, and keywords fields in the selected databases (detailed in Section 3.3). The following is the base search string used, adapted as necessary for the specific syntax of each database:

("Ombudsman" AND ("Crowdsourcing" OR "E-Government" OR "citizen-sourcing" OR "Citizen-participation" OR "e-participation" OR "electronic participation" OR "collaborative systems" OR "collective intelligence" OR "user-powered systems" OR "community systems" OR "user-generated content"))

This comprehensive search strategy, combining a structured PICO-based approach with a carefully constructed and iteratively refined search string, aimed to identify all relevant studies on the use of crowdsourcing in municipal ombudsman offices published within the specified timeframe and language parameters. The subsequent stages of the review, including study selection, quality assessment, and data extraction, are detailed in the following sections.

3.3. Databases

The databases used to obtain primary studies that aim to answer the research questions were: ACM Digital Library website[1], IEEE Digital Library[2], Scopus[3], and Springer Link[4]. Due to limited time, we decided to use the *Database Search* (set of digital libraries) and leave the use of the hybrid search strategy (Mourão et al., 2020) to search for relevant articles for an update of this work. The publication period considered was determined between 2010 and 2023.

3.4. Inclusion and Exclusion Criteria

We defined specific criteria that determine which articles will be considered eligible for analysis and which will be excluded from the scope of the research. We present the criteria, classified as Inclusion Criteria (IC) as shown in Table 1 and Exclusion Criteria (EC) as shown in Table 2:

Tab. 1 – Criteria adopted to include papers in the study.

	Inclusion Criteria
IC01	Studies for which the full text is accessible, ensuring a comprehensive and thorough analysis of the content.
IC02	Qualitative and quantitative research studies, as well as mixed-methods approaches, that provide relevant insights into the functions, challenges, and best practices of Municipal Ombudsman offices.
IC03	Peer-reviewed journal articles and conference papers.
IC04	Studies conducted in different regions or countries to capture a wide range of perspectives and contexts.
IC05	Studies that investigate the impact or effectiveness of implementing Crowdsourcing or Citizen-Sourcing in Municipal Ombudsman offices in promoting accountability, transparency, citizen empowerment, or improvement in service delivery.

Tab. 2 – Criteria adopted to exclude papers from the study.

	Exclusion Criteria
EC01	Multiple publications based on the same dataset or research project should not be included, selecting only the most comprehensive or recent publication.
EC02	Non-peer-reviewed sources such as blog posts, opinion articles, newspaper articles, and editorials.
EC03	Studies for which the full-text or adequate information is not available, preventing a comprehensive analysis and data extraction.
EC04	Studies published before the specified period (i.e., before 2010).
EC05	Studies published in languages other than English, as specified in the inclusion criteria.
EC06	Studies that do not address Crowdsourcing or Citizen-Sourcing in Municipal Ombudsman offices in promoting accountability, transparency, citizen empowerment, among other aspects.
EC07	Studies that do not focus on Municipal Ombudsman services or related concepts.

These meticulously defined inclusion and exclusion criteria, presented in Tables 1 and 2, served as the foundation for a rigorous study selection process. By applying these criteria systematically during both the title/abstract and full-text screening stages, we ensured that only the most relevant and appropriate studies

[1]http://portal.acm.org/
[2]http://ieeexplore.ieee.org
[3]http://www.scopus.com
[4]http://link.springer.com

were included in this review. This careful selection process enhances the validity and focus of the subsequent analysis. The next step in the methodology involved assessing the quality of the included studies, as detailed in the following section.

3.5. Criteria for Quality Assessment

We established 8 criteria for Quality Assessment (QA) of the selected studies. These criteria are essential to ensure the validity and reliability of the conclusions of the selected studies. Below is presented the set of 8 defined criteria, ranging from QA01 to QA08 as shown in Table 3.

Tab. 3 – Quality Assessment

	Quality Assessment
QA01	**Crowdsourcing or citizen-sourcing approach**: verifies whether the approach of the studies involves Crowdsourcing or Citizen-Sourcing techniques.
QA02	**Relevance and applicability to the Ombudsman context**: evaluates the relevance and applicability of the findings and conclusions of the studies concerning Ombudsman practices.
QA03	**Presentation of limitations**: checks whether the selected studies adequately present their limitations. This analysis is critical to ensure the transparency and integrity of the reviews.
QA04	**Discussion of results**: assesses whether the studies provide an in-depth discussion of the obtained results, contextualizing and interpreting the findings to provide additional suggestions.
QA05	**context description**: checks whether the studies provide sufficient information to understand the environment in which the research was conducted.
QA06	**Proposal validation**: examines the possibility that the techniques proposed in the studies were validated in a simulated environment, laboratory, or case study.
QA07	**Specification of proposed techniques**: checks the clarity and specificity of the techniques proposed in the studies, ensuring that the methodologies are detailed.
QA08	**Presentation of study objectives**: it examines whether the study objectives were presented clearly and comprehensively, allowing readers to understand the purposes of the research.

To ensure the rigor of this systematic literature review, a comprehensive quality assessment of the included studies was conducted. This assessment was guided by a set of eight criteria (QA01-QA08), detailed in Table 3, designed to evaluate both the methodological soundness of the studies and their relevance to the specific context of crowdsourcing in municipal ombudsman offices. These criteria encompass fundamental aspects of research quality, such as the clear presentation of study objectives (QA08), adequate description of the research context (QA05), and a thorough discussion of results and limitations (QA03, QA04).

Beyond general methodological considerations, the criteria also specifically address the core themes of this review. QA01 verifies the explicit involvement of crowdsourcing or citizen-sourcing approaches, acting as a crucial final check on the alignment with the inclusion criteria. QA02 directly assesses the relevance and applicability of the findings to the ombudsman context, ensuring that the synthesized knowledge is directly pertinent to the research questions. This criterion is particularly important for bridging the gap between general crowdsourcing research and the specific needs and challenges of municipal ombudsman offices.

For studies proposing novel crowdsourcing techniques or systems, criteria QA06 (Proposal Validation) and QA07 (Specification of Proposed Techniques) were applied. These criteria assess the extent to which proposed solutions have been empirically validated and whether the technical details are sufficiently described to allow for replication or adaptation. While not all included studies propose new techniques, these criteria are critical for evaluating the practical applicability and potential impact of the research. The collective application of these quality assessment criteria allows for a nuanced understanding of the strengths and weaknesses of the existing evidence base, informing the subsequent synthesis and interpretation of findings.

3.6. Data Extraction

Data extraction is a stage in the SLR where the goal is to systematically collect critical information from selected studies, transforming complex texts and results into organized data ready for analysis. For each of the analyzed papers, information was extracted to contribute to the analysis and address the raised questions.

We used the Parsifal[5] tool to provide a structured and organized SLR protocol. The details and the dataset collected that support the findings of this study are available at *Zenodo* in the link https://doi.org/10.5281/zenodo.10719418.

In the next Section, the execution will effectively take place, applying the search string to the selected databases, implementing the inclusion and exclusion criteria, applying quality attributes, and finally, extracting information according to the presented form.

4. Conducting the Review

After applying the search strings to their respective databases, the SLR protocol was executed to ensure that only studies of interest were among the selected ones.

4.1. Search in Databases and Collections

To facilitate an understanding of how the process unfolded, we will propose naming the stages, calling them steps. At this point, we present the details of our SLR process in the selected databases for the execution of this study, as well as the results obtained after the application of specific steps. As detailed earlier, certain criteria are used in the work selection process. The initial 5 steps eliminate articles that meet the requirements stipulated in the SLR protocol.

- **Step 1**: Consider only papers obtained through application of the search string in the databases;
- **Step 2**: Only papers published from 2010 onwards were considered;
- **Step 3**: Discard papers classified as Gray Literature (Short Papers, Theses, Dissertations, among others);
- **Step 4**: Consider only papers published in the English language;
- **Step 5**: Consider only papers published in the field of Computer Science.

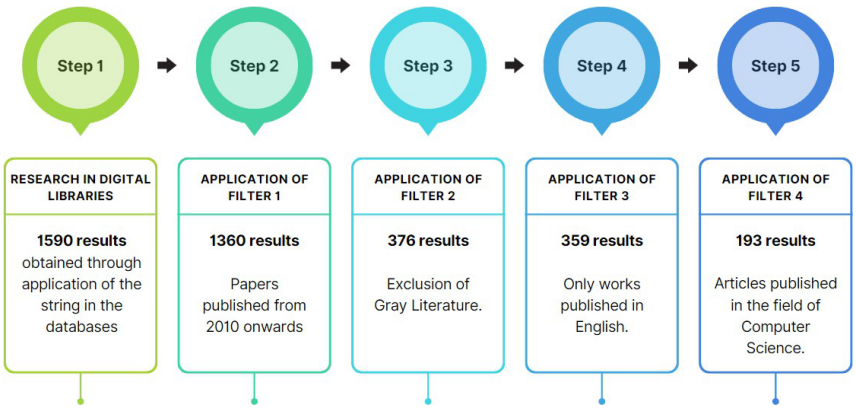

Fig. 1 – Steps applied during the search for articles in the databases.

The conduct of the SLR on all databases resulted in a total of 1.590 results. To ensure that the analysis focused on more contemporary studies, a filter was applied to include only works published from 2010 onwards (step 2 – 1), reducing the set to 1.360 articles. Next, the gray literature exclusion filter was applied, further reducing the number of results to 376 papers.

The language of publication was restricted to English, retaining the 359 articles already found. Additionally, we filtered the results, selecting only articles in the field of computer science, maintaining the set of 193 articles. These 193 articles resulting from this refinement process represent a foundation for the literature review. They will undergo an analysis based on the inclusion and exclusion criteria, as defined earlier.

[5]https://parsif.al/

4.2. Applying Inclusion and Exclusion Criteria

After refining the results obtained in the systematic literature mapping phase in all the databases surveyed, it was essential to conduct a quick assessment of the articles to ensure that only those meeting the final criteria were included in the systematic literature review.

In this stage of the process, the 193 articles resulting from the previous steps were subjected to an initial assessment. This assessment focused on the key elements of each article, including the title, abstract, introduction, and conclusion. Through this quick analysis, it was possible to identify articles that were not aligned with the inclusion criteria established earlier.

Inclusion and exclusion criteria are applied so that only articles that satisfy these criteria are kept within the scope of the mapping, while those that did not meet the final criteria were rejected for the next phase of the review. One of the exclusion criteria, for example, is the removal of duplicate articles. In this process, 25 articles that were imported were duplicates (the same article was found in at least two distinct databases).

This quick assessment approach ensured that only articles directly or indirectly related to and aligned with the research objectives were considered in the systematic literature mapping. Out of the 193 subjected to the criteria, only 24 satisfied them and will proceed to the detailed evaluation.

4.3. Temporal Distribution of Included Studies

The investigation of the timeline of studies helps to understand how the research field has evolved and how crowdsourcing and citizen-sourcing practices in municipal ombudsman offices have been addressed in academic literature. Figure 2 show the years 2017 and 2018 marked a period of substantial growth in research on the subject, with a total of seven articles published in these two years. The subsequent years, from 2019 to 2023, maintained a consistent level of interest.

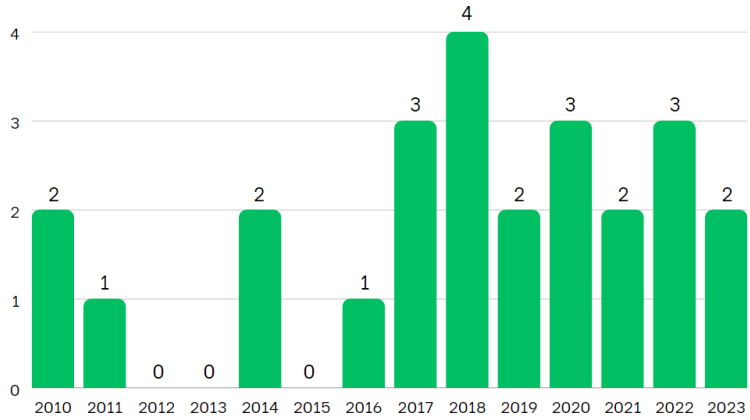

Fig. 2 – Temporal distribution of articles identified in the SLR.

Analysis of the publication timeline reveals a fluctuating but growing interest in crowdsourcing within municipal ombudsman offices. Initial interest was modest, with three articles published between 2010 and 2011. Following a period of inconsistent publication (two articles in 2014, one in 2016), a significant increase occurred in 2017-2018, with seven articles. The subsequent years (2019-2022) saw a sustained publication rate, with nine articles, suggesting continued relevance. Three articles were identified for 2023; however, this figure is partial due to potential indexing delays. This overall trend indicates an evolving field of inquiry.

Overall, the temporal distribution suggests an initial exploratory phase, followed by a period of increased research activity, and a subsequent stabilization, indicating an ongoing and evolving field of inquiry.

5. Answering the Research Questions

In this section, we answer the research questions defined in Section 3.1 and discuss them.

RQ1. *What are the main techniques of crowdsourcing and citizen-sourcing used in municipal ombudsman offices?*

The techniques of crowdsourcing and citizen-sourcing can be employed in municipal ombudsman offices to engage citizens in the process of information collection, problem-solving, and policy making (Certomà and Rizzi, 2017). These techniques leverage the collective wisdom of citizens to enhance governance and the delivery of public services (Grossman et al., 2018; Hammon and Hippner, 2012).

Among the accepted articles, Alenezy and Akhlaq, 2023; de Azambuja et al., 2014; Juk et al., 2021; Phatak, 2017, explicitly articulate a crowdsourcing-based solution for local government. While not functioning explicitly as ombudsman systems, they are deployed as a service connecting citizens with local government. Consequently, it can be inferred that the development of these solutions considered regional issues relevant to each area.

The approach presented in de Azambuja et al., 2014, describes "156 – Fala Porto Alegre," a channel used to address the demands of municipal citizens. It investigates how this channel integrates with the dimensions of a "Smart City Initiatives Framework." Although not explicitly using the terms "crowdsourcing" or "citizen-sourcing," the article discusses the integration of citizens' contributions into smart city initiatives, fitting the concept of citizen-sourcing.

The approach found in Phatak, 2017, explores the evolution of the public grievance resolution sector (PGRS) in Pakistan, emphasizing the use of information and communication technology in the complaint-handling process. The study examines how digital technologies are being used to address public complaints and improve the customer service process.

In Juk et al., 2021, the impact of the Covid-19 pandemic on public service delivery is discussed, along with the adoption of digital solutions. This article addresses digital transformation in complaint management and how services were adapted to meet citizens' needs during the pandemic.

Finally, Matos et al., 2021, describes a public complaint management system called "Fix-It," which utilizes an Android application to enable citizens to report incidents and issues to the public administration. The system involves citizens directly in communicating problems and improving public services, representing a form of citizen-sourcing.

These articles demonstrate various approaches to involving citizens in information collection, participation in problem-solving, and contributing to the improvement of municipal-level public services, even if the terms "crowdsourcing" and "citizen-sourcing" are not explicitly mentioned.

RQ2. *How have crowdsourcing and citizen-sourcing been applied to enhance citizen participation and engagement in municipal ombudsman offices?*

Crowdsourcing and citizen-sourcing have been applied to enhance citizen participation and engagement in municipal ombudsman offices in various ways. However, it is important to note that not all articles specifically address the use of these techniques in municipal ombudsman offices. Below, we highlight how these approaches are applied to improve engagement and citizen participation and which articles discuss these applications.

Crowdsourcing and citizen-sourcing are often used to collect feedback and complaints from citizens regarding public services and municipal issues. Citizens can report problems such as faulty infrastructure, lack of basic services, and environmental issues using digital platforms. Articles Adenskog et al., 2017; Alenezy and Akhlaq, 2023; Bonacin et al., 2010; Cho and Chun, 2011; Faber and Budding, 2018; Juk et al., 2021; Maciel et al., 2016; Matos et al., 2021; Phatak, 2017, mention similar approaches to **collecting feedback and complaints**.

Some municipal ombudsman offices employ crowdsourcing and citizen-sourcing to involve citizens in public consultations and decision-making processes. Citizens can contribute ideas, opinions, and suggestions through online platforms. Articles Bonacin et al., 2010; Cho and Chun, 2011; Pathmanathan and Poulier, 2017, address **public consultations and citizen participation**.

Crowdsourcing is used for the real-time **monitoring of public services**, where citizens report issues such as road potholes or lack of public lighting. This helps improve the accountability of municipal authorities. Articles Alenezy and Akhlaq, 2023; de Azambuja et al., 2014; Juk et al., 2021; Lanza et al., 2017; Matheus et al., 2010; Matos et al., 2021; Phatak, 2017; Przeybilovicz et al., 2014, mention the monitoring of public services.

Crowdsourcing and citizen-sourcing also **contribute to increased transparency** in government actions. Citizens have access to information about projects, budgets, and government activities through digital platforms. Article Villao et al., 2023 discusses the importance of transparency.

Citizen engagement is strengthened by improving communication between municipal authorities and citizens. Articles Adenskog et al., 2017; Alenezy and Akhlaq, 2023; Faber and Budding, 2018 mention **enhanced communication** through technologies.

In summary, the use of crowdsourcing and citizen-sourcing in municipal ombudsman offices has been applied to actively engage citizens, improve feedback collection, promote transparency, monitor public services, and strengthen communication between authorities and citizens. However, it is important to note that not all articles address these applications, and some focus on broader aspects of e-governance.

RQ3. *What are the reported results and benefits of using crowdsourcing and citizen-sourcing in municipal ombudsman offices?*

The selected studies in this research reveal various outcomes and benefits associated with the use of crowdsourcing and citizen-sourcing in municipal ombudsman offices. Some of the key identified outcomes and benefits include the improvement of citizen participation and engagement, increased transparency and accountability, identification of issues and solutions, among other points.

Articles Adenskog et al., 2017; Alenezy and Akhlaq, 2023; Bonacin et al., 2010; Cho and Chun, 2011; Juk et al., 2021; Maciel et al., 2016; Pathmanathan and Poulier, 2017; Ribeiro et al., 2018, cite how the use of citizen-sourcing often results in a significant increase in citizen participation, allowing more citizens to engage in solving municipal problems and policymaking. On the other hand, increased efficiency and problem resolution are discussed in Alenezy and Akhlaq, 2023; de Azambuja et al., 2014; Karkin and Janssen, 2020; Lanza et al., 2017; Phatak, 2017; Przeybilovicz et al., 2014, where it is demonstrated that real-time feedback collection and the ability of citizens to report issues directly to municipal authorities can lead to quicker and more efficient resolution of local issues.

The use of these techniques can enhance the transparency of municipal activities, making governmental information and processes more accessible to citizens. Articles Faber and Budding, 2018; Ingrams, 2018; Villao et al., 2023, discuss how these approaches can contribute to transparency. Contributions from citizens through crowdsourcing and citizen-sourcing provide feedback to municipal authorities, allowing them to better understand the needs and concerns of the community. Discussions presented in articles Bernardes et al., 2018; Matheus et al., 2010; Sharma et al., 2021 highlight the importance of feedback.

The ability for citizens to report issues directly can help authorities allocate resources more effectively and direct efforts where they are most needed, as discussed in Juk et al., 2021; Phatak, 2017; Przeybilovicz et al., 2014. Additionally, crowdsourcing and citizen-sourcing can also help identify emerging issues or trends that may not have been detected through traditional data collection methods, as mentioned in Maciel et al., 2016.

Lastly, by allowing citizens to actively participate in solving municipal problems, the use of crowdsourcing can promote citizen empowerment. The approaches Alenezy and Akhlaq, 2023; Bernardes et al., 2018; Cho and Chun, 2011; de Azambuja et al., 2014; Lanza et al., 2017 discuss how this can occur. These are some of the benefits found in the target articles studied so far.

RQ4. *What are the main limitations and challenges associated with the use of these practices in municipal ombudsman offices?*

The practices of crowdsourcing and citizen-sourcing in municipal ombudsman offices also face various limitations and challenges, as evidenced in several of the selected articles. Some of the key challenges and limitations identified are described in the next paragraph.

i **Digital Inequality**: Studies such as Przeybilovicz et al., 2014; Villao et al., 2023 highlight digital inequality as a significant challenge. Not all citizens have equal access to technology or digital skills, which can exclude vulnerable and marginalized groups from the participation process;
ii **Security and Privacy**: Articles Apleni and Smuts, 2020; Lanza et al., 2017 point out concerns about security and privacy in the use of crowdsourcing and citizen-sourcing. The collection and sharing of sensitive information can expose citizens to security risks and privacy breaches;
iii **Language and Cultural Barriers**: Maciel et al., 2016; Matheus et al., 2010; Villao et al., 2023 mention linguistic and cultural barriers as obstacles to effective participation. Ensuring that tools are accessible in different languages and culturally sensitive is a challenge;
iv **Credibility of Contributions**: Articles Adenskog et al., 2017; Ávila et al., 2022; Bernardes et al., 2018; Bonacin et al., 2010; Ingrams, 2018; Juk et al., 2021; Karkin and Janssen, 2020; Maciel et al., 2016; Matheus et al., 2010; Seidel, 2019; Villao et al., 2023 raise concerns about the credibility of citizens' contributions. It is important to distinguish between legitimate information and misleading or malicious content;
v **Institutional Resistance**: Bonacin et al., 2010; de Azambuja et al., 2014; Karkin and Janssen, 2020; Matheus et al., 2010; Sharma et al., 2021 point out that institutional resistance can be a challenge. Changes introduced by these practices may encounter resistance within existing government structures;
vi **Data Volume Management**: Articles like Faber and Budding, 2018; Pathmanathan and Poulier, 2017; Seidel, 2019 mention the challenge of managing large volumes of data generated by crowdsourcing and citizen-sourcing. Analyzing and interpreting this data can be time-consuming and require significant resources;
vii **Training and Capacity Building**: Studies including Adenskog et al., 2017; Bernardes et al., 2018; Bonacin et al., 2010; de Azambuja et al., 2014; Ingrams, 2018; Karkin and Janssen, 2020; Maciel et al., 2016; Matheus et al., 2010; Matos et al., 2021; Villao et al., 2023 emphasize the importance of training and capacity building for municipal staff to deal effectively with these practices. Lack of adequate skills can be a barrier;
viii **Legislation and Regulation**: Some articles, such as Adenskog et al., 2017; Bernardes et al., 2018; Juk et al., 2021; Pathmanathan and Poulier, 2017; Phatak, 2017; Villao et al., 2023, mention challenges related to legislation and regulation. Clear policies and regulations need to be developed to govern the use of crowdsourcing and citizen-sourcing;
ix **Platform Maintenance**: Studies like Alenezy and Akhlaq, 2023; Pathmanathan and Poulier, 2017 indicate that the continuous maintenance of digital platforms can be expensive and challenging. Ensuring that tools remain functional and up-to-date is crucial;
x **Exclusion of Marginalized Groups**: Most articles express concerns about the exclusion of marginalized groups—who may not have access to mobile devices or the Internet. This includes articles such as Bonacin et al., 2010; Durachman et al., 2020; Lanza et al., 2017; Matheus et al., 2010; Matos et al., 2021; Phatak, 2017; Przeybilovicz et al., 2014.

These challenges and limitations emphasize the importance of a careful and balanced approach when implementing crowdsourcing and citizen-sourcing in municipal ombudsman offices, considering the needs and concerns of all segments of society.

RQ5. *What methodological approaches are employed in evaluating the use of crowdsourcing and citizen-sourcing in municipal ombudsman offices?*

Various methodological approaches have been employed in assessing the use of crowdsourcing and citizen-sourcing in municipal ombudsman offices. Table 4 presents the identified methodological approaches and the articles that employ them.

These methodological approaches provided several perspectives and data to assess the use of crowdsourcing and citizen-sourcing in municipal ombudsman offices, enabling a more comprehensive understanding of their impacts and challenges.

6. Open Issues and Discussion

This systematic literature review has synthesized the current state of knowledge regarding the application of crowdsourcing in municipal ombudsman offices, revealing both promising opportunities and significant

Tab. 4 – Methodological approaches employed by each assessed paper.

Methodology	Approachs
Qualitative Research	Adenskog et al., 2017; Alenezy and Akhlaq, 2023; Ávila et al., 2022; Cho and Chun, 2011; Karkin and Janssen, 2020; Pathmanathan and Poulier, 2017; Phatak, 2017; Seidel, 2019
Quantitative Research	Faber and Budding, 2018; Lanza et al., 2017; Przeybilovicz et al., 2014; Ribeiro et al., 2018; Villao et al., 2023
Case Studies	Apleni and Smuts, 2020; Bernardes et al., 2018; Bonacin et al., 2010; de Azambuja et al., 2014; Juk et al., 2021; Matheus et al., 2010; Matos et al., 2021
Documentary Analysis	Ingrams, 2018; Maciel et al., 2016; Sharma et al., 2021
Content Analysis	Durachman et al., 2020; Sharma et al., 2021
Action Research	Pathmanathan and Poulier, 2017
Theoretical Models	Bernardes et al., 2018; Ingrams, 2018; Sharma et al., 2021
Platform Evaluation Methods	Alenezy and Akhlaq, 2023; Villao et al., 2023

challenges. While the findings demonstrate the potential of crowdsourcing to enhance citizen participation, improve service delivery, and promote government transparency, several key issues require further consideration and research.

A persistent theme across the reviewed literature is the challenge of the digital divide. Crowdsourcing initiatives, relying heavily on digital technology, can inadvertently exclude vulnerable and marginalized populations who lack access to the internet, necessary devices, or digital literacy skills (Przeybilovicz et al., 2014; Villao et al., 2023). This raises serious concerns about equity and representativeness, as simply deploying a crowdsourcing platform does not guarantee that all citizens will be able to participate equally. Future research must prioritize strategies to mitigate this digital exclusion.

The credibility and reliability of citizen-submitted data are also paramount for the success of crowdsourcing in ombudsman offices. The reviewed studies suggest the need for robust mechanisms to verify information, prevent the spread of misinformation, and address potential biases in participation (Adenskog et al., 2017; Ávila et al., 2022; Bernardes et al., 2018; Bonacin et al., 2010; Ingrams, 2018; Juk et al., 2021; Karkin and Janssen, 2020; Maciel et al., 2016; Matheus et al., 2010; Seidel, 2019; Villao et al., 2023). While some studies mention data validation techniques, there is a distinct lack of in-depth research on the effectiveness of different approaches within the specific context of ombudsman services. Future investigations should explore optimal strategies for data quality assurance.

The successful implementation of crowdsourcing requires seamless integration with existing ombudsman office workflows and processes. The literature reveals a wide range of integration levels, from standalone platforms to fully integrated systems (de Azambuja et al., 2014; Matos et al., 2021; Phatak, 2017). However, there is limited understanding of the organizational factors that facilitate or hinder this integration. Future research should investigate the impact of organizational structure, staff training and capacity building, and interdepartmental collaboration on the effectiveness of crowdsourcing initiatives. Comparative case studies examining different integration approaches could provide valuable, actionable insights for practitioners.

Beyond initial implementation, the long-term sustainability and scalability of these initiatives are often overlooked. Maintaining citizen engagement over time, ensuring ongoing platform maintenance and updates, and securing adequate funding are crucial, yet often under-researched, challenges (Alenezy and Akhlaq, 2023; Pathmanathan and Poulier, 2017). Future research should explore sustainable funding models (e.g., public-private partnerships, citizen-funded initiatives), strategies for fostering long-term citizen participation (e.g., gamification, feedback loops, community building), and the scalability of different crowdsourcing approaches to accommodate growing demands and evolving citizen needs.

The reviewed studies employ a variety of metrics to assess the impact of crowdsourcing, including participation rates, response times, and citizen satisfaction (Faber and Budding, 2018; Lanza et al., 2017; Przeybilovicz et al., 2014; Ribeiro et al., 2018; Villao et al., 2023). However, there is a lack of standardized metrics and a need for more rigorous evaluation methodologies. Future research should prioritize the development of

robust and meaningful indicators of success, considering both quantitative and qualitative measures. This includes exploring the impact of crowdsourcing on citizen empowerment, trust in government, and the overall effectiveness of ombudsman services.

Furthermore, research should move beyond short-term evaluations and investigate the long-term effects of crowdsourcing on ombudsman office performance and citizen-government relations. There are also several discussions involving how to empower citizens to take action, how those actions will impact their lives and how governments can enhance the use of those actions (Alenezy and Akhlaq, 2023; Bernardes et al., 2018; Cho and Chun, 2011; de Azambuja et al., 2014; Lanza et al., 2017).

7. Final Remarks and Future Works

After examining the studies addressing crowdsourcing and citizen-sourcing in municipal ombudsman offices, following the SLR protocol, it is possible to identify several trends and important conclusions. These studies provide insight into how these practices are being implemented, their implications, and the challenges faced in a municipal context.

One notable aspect when analyzing these studies is the diversity of methodological approaches adopted. This is indicative of the complexity and multidimensionality of the topic. One of the main motivations behind the adoption of these practices is to improve citizen participation and engagement in public policies and municipal services. The studies highlight that the use of these tools can enable citizens to actively participate in problem identification, provide feedback, and co-create solutions. This can strengthen the relationship between municipal government and its citizens, making the administration more responsive and transparent.

The examined studies suggest that crowdsourcing and citizen-sourcing have the potential to continue playing a significant role in municipal governance. However, for this to happen, it is crucial that municipal governments proactively address challenges and constraints, promote digital inclusion, and ensure the reliability and transparency of platforms.

While this systematic literature review offers a valuable synthesis of current knowledge, it has limitations that suggest future research directions. Our search, focused on specific databases and English publications, may have missed relevant studies. Quality assessment relied on the completeness and objectivity of reported information, and the limited research specifically on crowdsourcing in municipal ombudsman offices calls for further investigation. Specifically, future work should prioritize the longitudinal impacts of crowdsourcing on citizen empowerment and ombudsman effectiveness, enabling researchers and practitioners to refine implementation strategies and fully realize its transformative potential

Abstract. Governments are facing technical, organizational, political, financial, etc. limitations on their capacity to tackle major policy problems like pandemics, climate change, migration, etc. that endanger societal well-being, security, and development. Overcoming such limitations requires a collective response, where different members of the society – individuals and institutions – are working with government and each other to address the problem. The aim of this paper is to examine the digital transformation of government and whether the outcome – digital government – makes society stronger or weaker, thus facilitating or undermining such collective response. To this end, we examine six qualities of social development – inclusion, equality, justice, collectivism, order and democracy – which presence or absence make societies stronger or weaker, and collect the evidence from scientific literature of digital government impacting such qualities, leading to inclusive vs. exclusive societies, equal vs unequal societies, just vs. unjust societies, etc. The result of this research is a landscape of different approaches, experiences, and designs, through which digital government contributes to the presence or absence of these qualities. This result has both research and policy implications.

Keywords. Digital technology, digital government, social development, policy-relevance
Research paper, DOI: https://doi.org/10.59490/dgo.2025.1059

1. Introduction

Traditionally, digital government research has been focused on improved service delivery, efficient administration, open decision-making, and engaged citizens. The research was mainly driven by the problems that were internal to the government or the relationships between the government and citizens. More recently, the focus has been shifting to dealing with wicked problems like pandemics, climate change, migration, etc., that no government has the capacity to handle alone, and to problems of democratic breakup that require balancing government power with societal power. Addressing such problems requires institutions and individuals to work together for the well-being, security and prosperity of all members of the society i.e., a stronger society based on cohesion, solidarity, resilience, equity, inclusion and other values.

In view of such problems and various limitations facing governments – technical, organizational, political, financial etc. to tackle them alone, whether digital government strengthens or weakens collective capacity to tackle such problems is of significant social and policy concern. Both outcomes are possible. For example, while digital government can open different electronic and traditional channels to deliver digital public services, making them more accessible to people with disabilities, by enabling automation it can also increase the burden on receiving such services especially by the vulnerable groups, including the disabled (Estevez et al., 2024). The former makes

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

society more inclusive, the latter more exclusive. Another example, by improving civic engagement and access to public services, digital government can enhance social justice (Hulstijn et al., 2024) but not having enough digital literacy and capabilities to access digital government can also lead to inequitable treatment and disenfranchisement (McNeal et al., 2008). The former makes society more just, the latter more unjust.

Based on the above, the aim of the paper is to explore the impact of digital government on society. The research question pursued is stated in the title: Does digital government strengthen or weaken society? However, the concept of the strong or weak society depends on the discipline and context. It is not easy to define. Thus, we refine this notion in terms of six qualities of social development which presence or absence make societies stronger or weaker: inclusion, equality, justice, collectivism, order, and democracy. Thus, depending on the presence or absence of these qualities, we have six contrasting statements on the impact of digital government on social development: inclusive vs exclusive society, equal vs unequal society, just vs unjust society, collaborative vs individualistic society, orderly vs disorderly society, and democratic vs undemocratic society. We are not just looking at binary answers, e.g. whether digital government leads to inclusive or exclusive society; as demonstrated above, both outcomes are possible. Instead, we aim at discovering different approaches, experiences, evidence and mechanisms through which digital government contributes to the presence or absence of these qualities. We approach this aim by systematically searching through and exploring the body of scientific literature. The main outcome is the landscape of the impact of digital government on social development, structured along the eight social qualities.

The rest of this paper is organized as follows. Section 2 presents the background, including theoretical constructs for categorizing social development. Section 3 explains the main research question and the approach adopted to address it. Section 4 describes the findings – the impact of digital government on the six qualities of social development, one subsection per quality. Finally, Section 5 discusses the findings and their implications for research and practice, and concludes the study through highlights, limitations, and directions for future research.

2. Background

Many public administrations face the challenges of adapting to the rapid social change driven and facilitated by technological developments. Since such developments go beyond the mere adoption of technological novelties and generate (positive or negative) impacts on the functioning of our societies, many expectations are posited into this process. The impact of technology adoption on the functioning of public administrations to increase their efficiency (Hilhorst et al., 2022), transparency (Matheus et al., 2021), collaboration (Gil-Garcia et al., 2023), smartness (Estevez et al., 2021), etc. are well studied. However, the societal impact of government technology adoption have not received the same level of attention (Eom & Lee, 2022) or, when it does, the focus is either on trust creation using rather simplistic approaches (Dueñas-Cid & Calzati, 2023) or reflects a significant expectation-impact gap (MacLean & Titah, 2021). This contradiction has been highlighted in the academic literature. While texts focusing on the potential impact of technology to increase participatory and deliberative capacity of citizens (Mäkinen, 2006) or the speed of service delivery (Bekkers & Zouridis, 1999) are common, research on factual impacts uncovers lack of inclusivity in participatory use of technology (Loignon et al., 2021) or biases in service delivery (Clark et al., 2013). Thus, a paper approaching such contradictions and the discussion whether digital government strengthens or weakens societies is lacking in the literature.

Nevertheless, prior to such analysis, it is necessary to pose a question: what makes a society stronger or weaker? The question is not easy to tackle since might be different definitions of stronger or weaker society put forward by different academic disciplines. The approach to that question has traditionally been indirect, focusing on related concepts with a narrower and, therefore, easier to define scope. Social science classics, such as Émile Durkheim (1893), approached the “strength” of societies through the existence and meaning of social bonds between individuals. In traditional and simpler societies, societal ties are sustained by the similarity of their members and their feeling of pertinence to strong communities. In contrast, in modern societies, societal ties are more structural, stemming from the interdependence required to deliver wellbeing (Dueñas-Cid et al., 2023). Similarly, Tönnies (2012) is linking the strength of societies to the degree of interpersonal ties and collective consciousness, that in complex societies is formalized in laws and contracts by the state. Differently, Dahrendorf (1968) argued that societal strength is influenced by the ability to deal with and institutionalize conflict. Stronger societies find a better balance between consensus and conflict, which makes them more stable and adaptable. More recently, Putnam (1995) linked the decline in civic engagement and social networks to weakening social bonds and “weaker” societies. In contrast, strong social ties and active community participation indicate "strong" societies. Alexander (2012) put the focus of strong (civil) societies on the capacity to develop solidarity, inclusiveness, and a shared commitment to democratic values.

Thus, by providing laws and contracts, and adjudicating conflicts, the state is defined as the provider of societal strength. This is especially the case with the decline and weakening of interpersonal connections. According to Kirlin (1996), the role of governments is creating institutional frameworks to shape human activities. This

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

materializes in three activities: 1) creating conditions for collective decisions, 2) making decisions to define and protect communities, and 3) delivering services (Janowski, et.al., 2018). Referring to technological adoption, the role of the state is providing conditions to facilitate such adoption as well as fostering innovation and adjusting it to the regulatory and societal frameworks where they are to be implemented (Kattel et al., 2022). The state institutions should help adopt and implement technologies, lead innovation and regulate technology used by citizens, and ensure that the technological impact is meaningful and contributes to strengthening societies (OECD, 2024). But, how to measure this impact? And how to understand what is a stronger or weaker society?

The definition of stronger or weaker society might fall into the category of concepts with symbolic meaning but open to interpretation depending on the context (Laclau, 2018). For this reason, and given the reflexive nature of this academic piece, we approached the impact of digital government on stronger or weaker societies by separately discussing such impact on six qualities that characterize such societies: inclusion, equality, justice, collectivism, order, and democracy. A strong society is one where the quality is present. A weak one is where the quality is absent. This leads to six corresponding dichotomies in Table 1: inclusive vs exclusive, equal vs unequal, just vs unjust, collaborative vs individualistic, orderly vs disorderly, and democratic vs undemocratic.

Tab. 1 - Societal dichotomies

Quality	Dichotomy	Sources	
Inclusion	Inclusive vs exclusive society	An inclusive society "actively involves all individuals in social, political, and economic processes, ensuring that diverse perspectives are valued and represented" (Marmot, 2005)	An exclusive society creates "barriers that prevent certain groups from accessing resources and opportunities, often leading to marginalization and disenfranchisement" (Young, 1990)
Equality	Equal vs unequal society	An equal society is where "all individuals have equal rights and opportunities, and where disparities in wealth and power are minimized" (Sen, 1999)	In unequal societies "the concentration of wealth and power in the hands of a few [leads] to systemic disadvantages for large segments of the population" (Piketty, 2014)
Justice	Just vs unjust society	A just society is "structured to ensure that the basic rights and liberties of all its members are protected" (Rawls, 1971)	An unjust society "fails to provide its least advantaged members with the resources and opportunities necessary to thrive" (Rawls, 1971)
Collectivism	Collaborative vs individualistic society	A collaborative society is where "individuals recognize that they are part of a larger community and that their actions can significantly affect others" (Ostrom, 1990)	An individualistic society is where "individuals are expected to take care of only themselves and their immediate families" (Hofstede, 1984)
Order	Orderly vs disorderly society	An orderly society possesses "collective consciousness that ensures that individual actions are aligned with the norms and values of the community" (Durkheim, 1893)	In disorderly societies "social norms are challenged, leading to a state of anomie where individuals feel disconnected from the collective" (Weber, 2019)
Democracy	Democratic vs undemocratic society	A democratic society allows "citizens to participate in the political process, including the right to vote and the right to run for public office" (Dahl, 1998)	In undemocratic society there is "absence of competitive elections, the suppression of political opposition, and the restriction of civil liberties" (Diamond, 2008)

3. Methodology

The research question guiding this work is "Does digital government strengthen or weaken a society?". The question was motivated and justified in section 1 and grounded and theoretized based upon existing literature in section 2. In the current section, we explain how we approached developing an answer to this question. We followed a three-step approach based on qualitative research and secondary literature data.

First, we searched the literature for different social qualities and in what sense their presence or absence make societies stronger or weaker. In this step, we used the descriptive literature review (Paré et al., 2015) to identify representative work on different qualities of social development, and inform the scoping review in step 2. The process and result are presented in section 2 and summarized in Table 1.

Second, for each quality identified in step 1, we conducted two searches in the Scopus database to gather evidence in what sense and how exactly digital government can contribute to the presence or absence of this quality, and

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

thus to making the society stronger or weaker. Each search used a conjunction of two terms. One representing "digital government" and its various synonyms such as "digital governance", "e-government", "e-governance", "electronic government" or "electronic governance". Another representing the presence or absence of a given quality in society. For example, the presence of "inclusion" is expressed by: "inclusive", "equitable", "non-discriminatory", "non-racist", "unbiased" and "unprejudiced", the absence of "inclusion" is expressed by: "exclusive", "biased", "discriminatory", "inequitable", "prejudiced" and "restricted". To provide an initial indication of the size and scope of the literature, we followed the scoping literature review (Arksey, 2005).

Third, data analysis proceeded as follows. For each quality, we considered two sets of digital government-related papers, one representing the presence and another the absence of this quality. After reading the titles, abstracts and keywords, we selected the papers that most meaningfully document how digital government can contribute to the presence or absence of this quality, thus making society stronger or weaker. Based on the selected papers, we synthesized different approaches, experiences, evidence and mechanisms – policies, strategies, programs, projects, systems, etc. through which digital government contributes to the presence or absence of the quality. The findings are presented in the six subsections of Section 4, one subsection for each quality.

4. Findings

This section presents the research findings on the impact of digital government on the six qualities of social development presented in Table 1, one section each: inclusion – Section 4.1, equality – Section 4.2, justice – Section 4.3, collectivism – Section 4.4, order – Section 4.5, and democracy – Section 4.6.

4.1 Digital government for inclusive vs exclusive society

An inclusive society is "a society for all" in which every individual has rights and responsibilities, and an active role to play (United Nations, 1995). According to UNDESA (2016), five out of 11 principles of effective governance for sustainable development focus on inclusiveness – leaving no one behind, non-discrimination, participation, subsidiarity, and intergenerational equity. Social exclusion occurs on three levels – "economic exclusion from labour markets, social exclusion between people in civil society and the ever-expanding exclusionary activities of the criminal justice system and private security" giving rise to the "movement from an inclusive society of stability and homogeneity to an exclusive society of change and division" (Young, 1999).

Digital government enables reaching out to more citizens using multiple channels to deliver public services, where people can opt for the channels most suitable for them, and can shape the delivery format to make it more accessible to people with disabilities (Estevez, et al., 2024). Pro-inclusion digital government include the India Digital Ecosystem of Agriculture (Abhishek, 2022) which places farmers at the centre to promote their financial inclusion (Acharya et al., 2024). Another example is the provision of non-bureaucratic and transparent public services to citizens to supports their social inclusion and non-discrimination in Romania (Pripoaie et al., 2024). The contribution of digital government to a more inclusive society covers: 1) leaving no one behind – addressing the "needs and aspirations of all segments of society"; 2) non-discrimination – delivering "public services on general terms of equality, without distinction of any kind"; 3) participation – involving all political groups in matters that directly affect them so they can influence policy; 4) subsidiarity – being responsive to the needs and aspirations of all people; and 5) intergenerational equity – promoting prosperity and quality of life balancing the short- and long-term needs of today and future's generations (UNDESA, 2016).

According to the UNDESA (2024), governments overlook the importance of inclusivity and when public service delivery mostly relies on digital technologies, "those deprived of digital access, digital tools or digital literacy face obstacles in navigating the promises and potential of the digital era". Similarly, the automation of government can lower government decision quality. This includes street-level algorithms producing suboptimal decisions for borderline cases due to rules simplification, and the removal of exceptions to force binary decision. The most affected are the vulnerable groups who face increased bureaucracy for receiving services (Estevez, et al., 2024). For example, in South Korea, most web- and app-based information, financial, e-participation, and social welfare services are not inclusive for citizens of all ages and income levels (Kim et al., 2024). Excluding groups from accessing the Internet, increasing the burden for accessing public services to already marginalized persons, and not considering them in government decision-making are all building more exclusive societies (UNDESA, 2016).

4.2 Digital government for equal vs unequal society

Social equality means that individuals receive roughly the same resources and opportunities, while the "poorest 50% of the global population share just 8% of total income [and] the richest 10% […] earn over 50% of total income" (IISC, 2016). Economic inequalities depend on place of residence, gender, age, education, migration status, etc. Digital inequalities reflect historical patterns of inequality, such as employed vs. self-employed vs. unemployed, primary vs. secondary vs. tertiary education, urban vs. rural, men vs. women, etc. (ITU, 2018). Equality is intertwined with equity, which recognizes that people have different circumstances and allocates the resources

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

and opportunities to achieve equal outcomes (SSIR, 2025). Policy interventions can reduce or exacerbate inequalities (Zach et al., 2023), including digital government.

A study from Florida, USA, showed how the 311 number provided information and services to citizens and engaged them in service coproduction, contributed to equity in power restoration after the Hurricane Michael (Xu et al., 2020). Using this number, minority groups having greater needs but less political capital were able to raise government attention, narrowing the service delivery gap. Additionally, a study of 64 Asian and African countries, part of the One Belt One Road initiative, showed that globalization and digital government improve income equality by leveraging investments, job creation, and wage increases of unskilled staff (Ullah et al., 2021).

Digital government enabling automated government decisions may lead to societal inequality. For instance, computational algorithms relying on biased data may produce discriminatory results that disadvantage people based on their race (Fountain, 2022). Thus data quality and the algorithms establishing public service eligibility, acting on such data, are potential sources of biased decisions. Data quality strategies can guard against this effect (Udoh 2020). An example from Nepal, poor accountability, and weak digital governance and institutionalisation of policies can cause inequity in universal coverage of maternal and newborn health services (Khatri et al., 2023).

4.3 Digital government for just vs unjust society

According to Rawls (1971), social justice is grounded on three principles: liberty of everyone's inalienable rights, equal opportunity, and ensuring rights for disadvantaged groups on the distribution of economic benefits. Justice is expressed by the fairness of public institutions, their management and service provision, ensuring that every citizen experiences similar outcomes (Frederickson, 2015; Ruijer et al., 2023) and cannot be compromised by efficiency gains or convenience of the privileged (Rawls, 2017). Injustice exists in two forms: moral wrongs and the denial of equal rights, and disparities in the possession or access to information and knowledge (Fricker, 2007) resulting in unfair treatment of certain people or groups (Hulstijn et al., 2024).

Digital government is enhancing justice by improving civic participation, and extending access to electronic public services (Hulstijn, 2024). The latter can reduce the distance between the public and institutions as well as among members of the public (Sanchez et al., 2013). I also offers platforms for online engagement, allowing citizens to be heard (Welby, 2019), including traditionally excluded voices, overcoming their disadvantaged positions and yielding social justice (Harrison et al., 2011). The type and quality of participation play a key role in the distribution of power and counteracting inequality and enhancing justice (Donoghue, 2017). This facilitates access to those who due to social, cultural and economic reasons cannot benefit from those liberties (Cappelletti, 1993). Thanks to open data platforms, *s*takeholders have a greater influence on the outcomes that are in their collective interest (Sanchez et al., 2013). Technology can reduce barriers to information exchange and generate stronger social bonds, partnerships and connections (Sanchez et al., 2013).

Digital government also frequently generates inequality (Hulstijn et al., 2024). Individuals lacking digital literacy and Internet connection are denied the advantages of online services (van Dijk, 2005) and subjected to inequitable treatment and disenfranchisement (McNeal et al., 2008). AI-based decision-making use rules based on the patterns found in historical data which may contain stigmatization and prejudice, producing decisions that disproportionately affect marginalized groups (Lippert-Rasmussen, 2023). Algorithms and rules are difficult to monitor and control, also for public employees or courts (Lundberg, 2019) and may contain errors that cause unjust treatment and negatively affect people's lives (Citron, 2007). Lacking human control, they expose citizens to fraud and wrong decisions (SNO, 2020). Additionally, people who lack knowledge, skills, or power to demand service are vulnerable to unfair treatment (Hulstijn et al., 2024). Technology can even amplify inequalities, as the eID system using identification through fingerprints (physical workers may be missing them) or irises (unscannable due to malnutrition), denying essential subsidies to many (Taylor, 2017).

4.4 Digital government for collaborative vs individualistic society

The complexity of modern societies is triggering the individualizing process, abandoning ways of functioning of traditional societies (Durkheim, 1893; Simmel, 1903). This effects the American society (Putnam, 1995), where individuals are constantly negotiating their identities (Giddens, 1990), and society reevaluates how institutions transmit norms of social action (Martuccelli, 2009). Increasingly, individuals are given more space to make sense of their life trajectories, expanding their capacity for self-reflection (Dubet, 1994). Technology, both a driver and a result of social transformation, acts as a catalyst for this individualization and lays the foundation for collaboration renewal. Both run in parallel but follow different rhythms: while technology's contributions to individualization are constant and latent, its contributions to collaboration are sporadic and deliberate. Technologies used in public administration, hence, can contribute in both directions. Technologies aligning with individualization are looking for user convenience and tailored service provision, while technologies fostering collaboration look for engagement and respond to the ideals of the common good.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Digital administration does make conscious efforts to create spaces for collaboration among individuals, aiming to connect them with common activities (Hammerschmid et al., 2023). Initiatives related to citizen participation often use digital technologies to encourage physical participation or to channel participation digitally, without direct contact but facilitating exchange and deliberation (Borge et al, 2023). Other forms of open government seek to engage the population in co-creation and co-management of administrative tasks (Nikiforova et al., 2023). However, these efforts face challenges similar to in-person initiatives. These include participants' segmentation, where only the most active engage, and the challenges of attracting certain groups even when they are central to the topic at hand. Many individuals feel ignored by the administration or lack the digital skills to participate.

Digital government has not escaped the individualistic trend. The availability of data on individual activity enables personalized forms of interaction, with governments being a major collector of such data. This facilitates personalized services, tailored to individual needs and driven by available data (Maksimova et al., 2021). This need not mean promoting individualization but adapting to the social process and reflecting the consumerization of digital government (Gaß et al., 2015). Other areas include the fragmentation of previously collective processes, such as social or electoral participation, which become remote (Unt et al., 2017), running in parallel with other processes that reduce interpersonal contact by depersonalizing service provision (Pieterson et al., 2007). The local administration which played a central role in social life, has its influence weakened due to digitalization. Digital government does not appear to be a primary driver of individualization, it adapts to this trend.

4.5 Digital government for orderly vs disorderly society

According to Durkheim (2018), social order entails the establishment of commonly shared beliefs, values, norms, practices, and interactions of daily life. Social order can be imposed (Kurawa, 2012) or part of "social contract" that transfers individual liberties to a coercive state in return for security of persons and their properties, and the establishment of dispute-resolution mechanisms (Hechte & Horne, 2003). Conversely, "disorder" is the non-compliance of norms (Weber, 2019) or delinquency of individuals against established rules (Wilson et al., 1982), resulting in unrest, crime, polarization, protests, etc. Not every disagreement is a disorder, e.g. worker strikes, but rigid response to unrest can lead to escalating levels of disorder. A certain degree of disorder may represent a democratic and inclusive society (Marshall, 2010) or give a rise to new order (Kurawa, 2012).

Digital government is recognized for its potential to enhance social order. Adequate service quality provisioned by government enhances stability and accountability (Amiantova et al., 2021). Enhanced efficiency and transparency represent predictability, a key element in social order (Janssen et al., 2015). Against citizen disappointment resulting in unrest, accessible and efficient services build trust and confidence (Bell et al., 2022). So is improved two-way interaction between government and citizens (Drummond et al., 2023). Digital government platforms (Bonina et al., 2021) facilitate collaboration, from information sharing through co-production to self-governance (Linders, 2012). They also channel dispute resolution, reducing dissatisfaction (Lukman et al., 2024), defusing collective action (Hu, et al., 2024), and enhancing respect to rules.

Governments can also use technology-based means to tighten social control through surveillance technologies like in China (Lee, 2019) or India (Rao et al., 2019). Using predictive policing (Graham, 1998), governments introduce 'data politics' (Ruppert et al., 2017) or 'digital authoritarianism' (Dragu et al., 2021) for political dominance and control (Bulman et al., 2021). Monitoring political opponents through technology-based mechanisms, so-called preventive repression (Dragu & Przeworski, 2019), results in extensive surveillance and control and destabilizing the balance of power between the state and citizens (Schlæger, 2013; Rao et al., 2019). The wide use of surveillance infrastructure increases the exposure to cyber-attacks, which ultimately destabilize society. In 2007, Estonia experienced cybersecurity incidents disrupting government and business institutions, heightening tensions among ethnic groups and raising social instability (Evron, 2008).

4.6 Digital government for democratic vs undemocratic society

Responding to political disaffection of citizens, recent years were prolific in technologies to improve democracy (Torcal, 2003). According to Fierro et al. (2022), this disaffection is the result of the lack of citizen engagement and responsiveness by the authorities. Technology, hence, has been called to help improve the capacity of citizens to engage with institutions and the institutions' capacity to interact with citizens (Sandoval-Almazán et al., 2017). We can also see how some technologies fail to produce the expected outcomes for technical (Dueñas-Cid, 2024), organizational (Dueñas-Cid et al., 2020) or societal (Toots, 2019) reasons. Certain technologies also challenge the democracy (Musiani, 2014) or are exploited by nondemocratic regimes (Romanov & Kabanov, 2020).

The evidence of technology use to improve the democracy is diverse. Some efforts are centred on increasing user convenience and lowering the participation barriers, the assumption being that those interested will participate (Dueñas-Cid et al., 2025). The search for usability has been quite successful, and technology increased inclusivity (Bricout et al., 2021) and reduced the cost of participation (Ford, 2021). Technology also enriched participatory practices (Stein, 2025), and forms of engagement (James et al., 2023) and interaction with representatives (Scacco

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

et al., 2021). The COVID-19 pandemic forced a rethink of democratic practices and considering alternatives (Rodríguez-Pérez et al., 2020). One example is internet voting, i.e. casting election ballots online, which several countries consider for voting abroad and, increasingly, domestically.

Technology is also partly blamed for democratic decline. Some argue that it desacralizes democratic rituals and makes participation less social (Unt et al., 2017). Concerns are also raised that voting in non-supervised environments might facilitate coercion (Kulyk et al., 2020) or buying (Benoist et al., 2007) as happens with postal voting (Shenker et al., 2014). However, technology also provides preventive measures. Voting technologies are adopted by countries with dubious democratic standards, raising the risk of external attacks and manipulating results. The use of social media by political agents, including government, is also contributing to political tensions and undermining the democratic functioning (Reisach, 2021). Governments are generally unable to reduce the harm created by social media while political agents take advantage to gain influence (Gupta-Carlson, 2016) or use data irregularly to tailor their political campaigns (Hinds et al., 2020).

5. Conclusions

The main research question pursued in this article was: Does digital government strengthen or weaken society? To answer this question, we identified a rich body of literature documenting the impact of digital government, with varying direction, nature, scope and origin of impact, on six qualities of social development. We uncovered the use of many technologies – artificial intelligence, cybersecurity, digital identification, digital platforms, internet voting and social media; and design concepts – digital authoritarianism, co-creation and co-production, dispute resolution, multi-channel service delivery, open data platforms, predictive policing, self-governance, service personalization, street-level algorithms, surveillance, two-directional interaction, and unattended AI-based decision-making. We also uncovered system analysis – 311 number, electronic identification using fingerprints and iris scanning, and cybersecurity incidents; as well as national initiatives from China, Estonia, India, Nepal, Romania and South Korea, and international ones like the One Belt One Road. Table 2 summarizes some examples from Section 4 how digital government impacts the six qualities of social development.

Tab. 2 – Digital government impact on the six qualities of social development

Quality	Digital government impact on the quality	
	Positive impact	Negative impact
Inclusion	Delivering public services through multiple channels to reach out, shaping the delivery format to fit the needs of the audience.	Excluding groups lacking digital access or skills, increasing burden on the vulnerable from automated services.
Equality	Service coproduction by minority groups with greater needs but less political capital can narrow the service delivery gap.	Algorithms relying on historical data may be sources of bias, causing inequality treatment of different social groups.
Justice	Platforms for online engagement, allow excluded voices to be heard, and yield decisions characterized by social justice.	Closed algorithms and the rules/data on which they act expose citizens, especially the vulnerable, to wrongful decisions.
Collectivism	Creating personalized services, tailored to individual needs and driven by available data, depersonalizing service provision.	Creating collaboration spaces by connecting citizens with common activities – exchange, deliberation, co-creation, etc.
Order	Platforms channel dispute resolution, reduce dissatisfaction, and defuse collective actions, facilitate social order.	Digital surveillance, repression and authoritarianism destabilize the balance of power between the state and citizens.
Democracy	Increasing user convenience, new forms of engagement, and lowering the barriers to participation in democratic processes.	The use of social media contributing to political tension and undermining the functioning of the democratic life.

This work has four main research implications. Against predominant focus in digital government research on digital transformation of public administration and government-citizen relationships, it sets forth to study the impact of digital government on citizen-citizen relationships and social development in general. It outlines a methodology to tackle the research question based on qualitative research and literature review. It uncovers six qualities of social development – inclusion, equality, justice, collectivism, order and democracy, to measure the impact of digital government. It offers initial results on the nature of that impact - approaches, experiences, and designs, uncovering the complex nature of the relationship between digital government and social development.

This work also has some policy implications. First, digital government exerts a significant and wide-ranging impact on social development, documented across all six qualities of such development. Second, the evidence confirms positive and negative impact, strengthening or weakening society by ensuring the presence or absence of the qualities. Third, to impact societal development, digital government employs a wide range of technologies, designs and policy contexts. Fourth, this diversity may explain radically different outcomes and highlight the importance

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

of explicit social impact goals, and technology, design and policy decisions to match them.

This research has some limitations. The first its limited theoretical background and thus the coverage of relevant qualities of social development; some qualities like, e.g. coherence – integrated vs polarized society, and freedom – free vs oppressed society are missing from the study. The second is not strictly following the systematic literature review and employing rather liberal decisions about excluding certain literature positions. Thus, the documented impact of digital government on social development falls short of being comprehensive. The third is the analysis not accounting for different qualities influencing each other, e.g. inclusion influencing equality, equality justice, justice order, etc. and vice-versa. Thus, some qualities may share literature. The fourth is the lack of policy analysis to complement literature analysis, to establish measurable impact of digital government on social development in various national and sectoral contexts.

Future work might focus on overcoming some of these limitations. One direction of future research is pursuing a study of the qualities of social development impacted by digital government, aimed at producing a theoretical framework able to measure the nature, direction, source and scale of the impact. The second is applying this framework to landscape the impact of digital government on social development based on the systematic review of the scientific and policy literature. The third is focusing the impact studies on specific countries or regions, to inform digital government design for achieving the expected social development outcomes. How such outcomes (and indirectly digital government) can enable the whole-of-society response to major policy problems like pandemics, climate change, migration, etc. is yet another direction. Finally, the complex nature of the societal impact limits the mitigation/reinforcement strategies to be valid for every technology, administration or society. Thus the fifth direction is examining specific cases of technology use for concrete administrations and societies to assess their impact and inform relevant mitigation/reinforcement strategies for the negative/positive impact.

Towards an empowered 'Platform State'? Digital Platforms, Infrastructural Power, and the Transformation of State Authority

Gianmarco Cristofari [a*] and Paolo Gerbaudo[b]

Submitted: 31 January 2025, Revised: 26 March 2025, Accepted: 21 April 2025, Published: 20 May 2025

Abstract. Over the last decade much of the scholarly discussion about the digital transformation of the state has focused on the notion of "platformization". This term serves to refer to the way in which governments and public services are ever more strictly associated with the operation of various digital platforms, thus seemingly acquiring some of their properties. Despite this centrality of the notion of platformization of the state, to date there has been surprisingly little theoretical reflection about the underlying organizational logic of the "platform state". Why is the state becoming "platformized"? Is it simply an attempt by government to update its functioning by absorbing the prevailing social logic of organization, as it has already been popularized by various companies; or is there something more structural and profound to this trend? We argue that in fact states and platforms – while pertaining to different categories and domains – share important organizational logics: an "ambient-making" power; a meta-organizational capacity; a centralizing drive; and most importantly a strong "infrastructural" power, to follow the terms of US sociologist Michael Mann. Using this concept we explain the reason why digital platforms appear to have progressively encroached on a variety of functions that tended to be typically state functions: functions that concern identification; the setting up of fundamental conditional operations of society; the affording of various "enabling" systems, lacking which individuals and collective actors cannot operate. Hence, the convergence between governments and platforms is not just a "marriage of convenience". Rather the process of platformization is for states an opportunity to reclaim some of their state capacity and practical power – and in particular infrastructural power – that they seem to have previously lost.

Keywords: Digital Government; Platforms; Platformization; Infrastructural Power

1. Introduction

One of the fundamental aspects that need to be developed to capture the digital transformation of government concerns the trend of "platformization of the state". This phrase has often been used to capture the transformation of governments and public services in a direction similar to that of global digital platforms that have become a mainstay of the present digital society (see for example, Chevallier, 2018; Bender & Heine, 2021; Iaione, 2020; Tammpuu et al., 2022). It indicates how governments create a variety of interconnected online services, through which citizens can perform different tasks, such as filing their tax returns or claiming benefits, and the progressive integration between these variety of state functions. In this sense, the platformization of the state appears as a trend that parallels other processes of platformization that are taking place in other domains and sectors of what is generally described as a "platform society" (van Dijck and Poell, 2018).

This transformation of the state towards the model of digital platforms is a trend that evidently carries major consequences for society, given the centrality of the state in our social structure. In their review of the different trends of social transformation led by digital technology, Hendrikse et al. (2022) have highlighted that the rise of the "platform state" is one of the most significant factors. Yet, while we know much about the consequences of platformization in other social domains – such as consumption, social relationships, patterns of labour, media audiences (Poell, Nieborg and Duffy, 2022), as well as forms of political organization (Gerbaudo, 2019) – we still know relatively little about the implications of the platformization of the state. More generally, we seem to lack a clear definition of what is meant by the phrase "platform state" or "platform government". The phrase's meaning has not yet been explicitly defined, rather it is mostly alluded to in a metaphorical way, by suggesting the existence of an analogy between the process of digital transformation of the state and a discussion of what happens in other domains. This lack of clear definition seriously limits our understanding of the term and our ability to deploy it in a rigorous way as an analytical category, to develop empirical research on the digital transformation of the state.

We aim at filling this gap by developing a definition of the platform state which draws on the similarities and convergences between the internal logic of states and platforms. We use the notion of infrastructural power developed by US sociologist Micheal Mann (1984) as a means to explain what state and digital platforms share. In so doing, we approach the *platform state as a historically specific manifestation of the state form which avails itself of the logic of the digital platform* (Cristofari, 2022) and that is the result of a proactive policy by state actors aiming at adapting the state to the challenges of the digital era (Chevallier 2018) as a *means of recuperating state capacity by tapping into the infrastructural potential of digital platforms*. It is in fact true that given the broad meaning of the word 'platform', the state can be considered as a platform *ante litteram*, given the way in which it has traditionally provided some key foundations for the functioning of society as a whole, which enable all sorts of other social functions. In turn commercial platforms have *de facto* come to acquire an infrastructural power, which we understand as a power of "ambient-creation" setting the environment for all sorts of other operations and transactions that traditionally was attributed to the state. Hence, the convergence between the state and digital platforms in the form of the platform state is more than a technical modification of the state form or a pure marriage of convenience, but as it were a redoubling of the fundamental logic of the state and its adaptation to the technological conditions of the digital era.

In our analysis we contend with those authors who see the power of the state as declining or bound to decline in the digital era, as a result of the power of digital platforms and the way in which they are stealing away forms of sovereignty that were previously the preserve of the state (Castells, 2000; Owen 2015; Zuboff 2019; Ledonvirtha, 2022). We suggest that the platform state embodies a reassertion of authority of government power by means of digital platforms. We make this argument in a two-pronged way. First, we propose that while private platform companies acquired forms of "infrastructural power" that were previously the preserve of the state, they have done so under the auspices of the governments of their country of incorporation and often serving implicitly as a means of state projection – as seen most clearly in the case of the US, and the relationship between Silicon Valley corporations and the defence and security apparatus of the state. Second, we suggest that now many states have realized the infrastructural importance of platform technologies and are trying to deploy it in the territories they control, leading to new forms of control, surveillance, and direction which raise new political and ethical issues. We conclude arguing that these changes call for a fundamental redirection of debates on the state and on digital transformation.

2. The state as a platform *ante litteram*

To make sense of the nature of the "platform state" entails approaching this phenomenon as one of many historical manifestations of the state form and exploring the similarities between the logic of the state and that of digital platforms. In this sense, the platform state is a concept whose logic of signification is analogous to notions such as the "welfare state" or the "regulatory state" (Moran, 2002, Pildes and Sunstein, 1995), or the "carceral state" (Weaver and Lerman, 2010); namely it is a term that indicates a specific logic of statecraft. More specifically, the platform state is a form state whose nature is fundamentally defined by the information communication infrastructure (ICI) that enables it.

Speaking of the general organizational logic of the state seems at the outset to be an almost insurmountable challenge due the almost all-encompassing power of the notion. The term is customarily utilized as a short-hand to define the varied complex of public institutions, ranging from government (sometimes used as a more reductive synonym) to the other fundamental public powers such as the legislative and the judiciary; police and the armed forces various public services, such as education, health, and the sprawling welfare state that emerged during the post-war decades. What matters for the understanding of the "state-form" is not just an identification of its disparate functions, but also an appreciation of their overarching logic. For Italian political scientist d'Entreves there are three ways we can approach the state as force, as power and as authority (1967). The first one is the most obvious; it is the definition embedded in Max Weber's famous assertion that the state possesses the "monopoly over legitimate violence". The second level, power instead focuses on the nature of the state as an organization bestowed with legitimacy emanating from the laws which the state itself emanates and based on which the state operates: the state is not just power; it is legitimate power. Finally, the element of authority instead highlights the political nature of the state, the fact that it relies on a certain ability to persuade its citizens and mobilize public opinion.

From Hobbes's discussion of the Leviathan as a centre of authority, to Locke's discussion of government and later Max Weber's discussion of bureaucracy, a variety of authors coincide in attributing to the state this centralizing power of control over a territory and population, which is usually condensed in juridical debates by the notion of *sovereignty of the state*. However, when it comes to developing an understanding of the historical transformation of the state-form in a digital era, what is most interesting is not much the principle of sovereignty as a normative entity, but rather its practical application and its enabling conditions, or what is often described as "state capacity". This is where Michael Mann's notion of "infrastructural power comes particularly handy.

The notion of "infrastructural power" was first put forward by Michael Mann, who understood it as the "institutional capacity of a central state […] to penetrate its territories and logistically implement decisions" (1984, 113). This concept has been traditionally associated with the state, but we believe that it also applies to platforms because of their dual roles as service enablers and as regulatory authorities. In the case of Mann, he distinguished the 'weberian' concept of infrastructural power from 'despotic power' and raw coercion linked to the marxist tradition. Building on Mann's work, Hillel Soifer defined infrastructural power as 'the aspect of the state that determines how far its bureaucracy can reach to exert control and regulate social relations' (Soifer 2008, 234). Mann (2008) presents income tax as the purest form of infrastructural power, "whereby our salaries are assessed and taxed 'at source' every month without our being able to intervene in the process." He further observes that income taxes only became major sources of state revenue in the twentieth century, whereas earlier, states were largely limited to "taxing things that visibly moved around" (Mann 2008). Similarly, other examples of infrastructural power include state practices of identification, employing technologies such as fingerprinting, retinal scans, and passports (Soifer, 2008).

We can use the notion of infrastructural power as a key term in exploring the similarities between the state and digital platforms (Tab. 1). As we show, there are key parallelisms between the operations of the state and digital platforms as sources of infrastructural power. The state, following Mann's discussion, typically provides key infrastructural services such as roads, security, and information, which then enable the operations of other actors, such as individuals and companies. Digital platforms also typically deploy an infrastructural function as they provide various affordances that allow individuals to perform various actions, to complete transactions, to identify themselves in front of other parties. This in turn is supported by different notions of authority and specific forms of infrastructural power. The infrastructural power of the state is concerned with using tools like taxation and identification which in turn stems from notions of citizenship as membership in a corporate organisation. In partly similar though also significantly different ways, the infrastructural power of platforms instead relies on socio-technical affordances such as ID systems, user profiles, databases and algorithms as a means to organise user behavior. In the continuation of the chapter we will develop this discussion further: first by looking at how infrastructural power found traditionally in the state is now mirrored by the infrastructural power of platforms, and then approaching the platformization of the state as an interpolation of the infrastructural logic of both states and platforms.

Table 1 – Parallelism between infrastructural features of the state and features of the digital platform

Aspect	State	Digital Platform
Service Provision	Provides essential infrastructure (e.g., roads, public data) and enables private sector services	Provides digital infrastructure (e.g., APIs, app stores) enabling user-created services and app
Authority over Population & Territory	Exerts authority over physical territory and citizens, setting laws and regulations	Exerts authority over a digital territory and users through terms of service and reprogrammable software
Infrastructural Power	Uses tools like taxation and identification (e.g., passports) to regulate and track citizens	Uses data collection, digital IDs, and algorithms to monitor and influence, redirect user behavior

3. The digital platform's "ambient power"

The rise of digital platforms is by now widely considered as one of the most important trends of socio-economic transformation in contemporary societies. It is a trend associated mainly with the rise of global corporations—often referred to as "GAFAM" (Google, Apple, Facebook, Amazon, Microsoft) and "BATX" (Baidu, Alibaba, Tencent, Xiaomi)—which play a pivotal role in the lives of Western citizens. These platform companies have achieved dominance in specific markets and have leveraged this success to expand into other sectors, creating interactional ecosystems of users and producers of services (Srnicek, 2016; Petit, 2020). The unprecedented dominance of platform companies has not gone unnoticed by scholars. Some have highlighted how these entities now perform roles traditionally associated with public authorities (Pollicino, 2021; Golia, 2023); others have noted that they increasingly resemble administrative bodies, issuing self-enforcing authorizations (Ranchordas, 2023) or even functioning as "autonomous global legal orders" (Bassan, 2021), and as agents implicated in an "infrastructural transformation of the public sphere" (Nosthoff & Maschewski, 2024).

While there are many definitions of platforms across various disciplinary perspectives (Cristofari, 2024), most researchers now agree on a 'minimal definition.' This defines platforms as intermediary organizational forms that connect two or more sides, providing the infrastructure necessary to facilitate interactions between different groups that build their services upon it (Schüler & Petrik, 2021). Classical examples of platform companies are Google's search engines, Uber, and Amazon Marketplace. From a technical perspective, platforms utilize technical standards to centralize control over their infrastructure (Bratton, 2016) and operate through a feedback loop between data collection and infrastructure reprogrammability. In other terms, the platform activity consists in organizing interactions—encompassing both users and service providers—by systematically collecting, processing, monetizing, and circulating data through algorithmic processes (Poell et al., 2019).

The platform can be viewed essentially as a *cybernetic form of government* that combines legal rules (terms of services) with actionable software. Like the modern state needed a grid to make sense of its citizens (Scott, 1998), the platform form of government is based on a certain legibility of users and on intense datafication. This ability of creating a controllable environment, act on users and reprogramming affordances has been variously described as algorithmic governmentality (Rouvroy & Stiegler 2016), governance by infrastructure (Musiani et al. 2016), regulation by design (Hildebrandt, 2013), and technological management (Brownsword 2016). This power relies on technical tools such as Application Program Interfaces (APIs), which determine the conditions under which data is collected from smartphones by apps and related services. APIs also enable bi-directional flows of data between platforms, facilitating the ongoing control and organization of interactions within the platform ecosystem (Maruping & Matook 2020; Lamothe et al 2021). As a consequence, platforms present what could be called an "ambient-making" power: organizing social relationships and determining who is connected or disconnected within specific spatial and temporal contexts. In so doing, platforms create a clear distinction between their "inside" (users and producers connected via devices) and the "outside" (the social and institutional environment in which the platform operates).

This requires continuous efforts to manage and organize its ecosystem, and scholars have theorized this activity into three key components: regulation (establishing standards), moderation (e.g., the process of monitoring, reviewing, and managing user-generated content), and curation (determining the relevance of content by deciding what and how to present it to users) (Poell et al., 2021). As such, the platform's "ambient-making

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

.

power" lies in its ability to create a structured field of action where a variety of tasks can be executed. In cybernetic terms, the platform performs 'selection of selections', reducing the complexity for other actors.

The implication of such a new organizational form primarily deals with the creation and organization of markets. The platform is indeed *more than a market* in the coordination of people, money and services in space-time. Platform marketplaces create interactional ecosystems that can be, to a certain extent, centrally controlled. These are recursive markets within the 'Market' in which social groups are coopted by turning them into scalable assets (Chicchi et al. 2022; Birch 2017). Attention to the forms of political planning on the 'inside' is essential to understanding the innovation of the platform model. Platform corporations make plans within their own ecosystem of complementors, to the point that ven liberal thinkers have criticized the asymmetrical distribution of knowledge created by platforms, disrupting the Hayekian ideal of an "equal amount of ignorance about the market." Surveillance capitalist platforms, as Zuboff (2019) argues, can "see the invisible hand" of the market and actively manipulate it. In this sense, the platform represents an organizational form that transcends the traditional dichotomy between centralization and decentralization—assuming such a dichotomy ever truly existed. It occupies a space between market and government: centralizing data collection, infrastructural reprogrammability, and political planning, while simultaneously decentralizing decision-making through the widespread distribution of reprogrammable interfaces. As such, the 'platform' should be considered a new organizational or institutional form that represents a historical break from traditional structures like hierarchies, markets, and networks (Cristofari 2024; Bratton, 2016; Van Doorn, 2020; Vallas & Schor 2020).

According to some authors this growing power of digital platforms leads to a weakening of the state. Three pivotal works—Manuel Castells' *The Rise of the Network Society* (2000), Taylor Owen's *Disruptive Power* (2015), and Vili Lehdonvirta's *Cloud Empires* (2022)—each argue that states, once powerful central authorities, are increasingly challenged by the rise of networked structures and global platform corporations. Castells saw a rise of a "network state" that collaborates with and competes against other global actors. In this new model, the state shifts from exercising absolute sovereignty to acting as a flexible node in a multi-layered governance system, constantly negotiating authority with non-state actors (Castells 2000).

Taylor Owen has pointed to examples such as Anonymous, Bitcoin, social media-fueled protests, the rise of Pirate Parties and open-source mapping platforms like Ushahidi to illustrate how digital technologies and networks disrupt the state's traditional monopoly on information and influence (Owen, 2015). He noticed that "collecting data and publishing maps were once the sole privilege of the state" (p. 125). This weakening of the state is the product of the disruptive power he attributes to social media in which the state's "institutionalized structures and norms that lead to lethargy, waste, inefficiency, and a lack of innovation" (p. 8) are easily out-maneuvered by the flexible, mobile and sprawling nature of networks. Thereby, "enabled by digital technology, disruptive innovators are now able to influence the behavior of large numbers of people without many of the societal constraints that have developed around state action" (p.9).

In *Cloud Empires* (2022), Vili Lehdonvirta takes this argument further, positing that tech giants now act as "virtual states" with power comparable to that of traditional governments. Lehdonvirta argues that the CEOs of major tech firms have, in many ways, become more powerful than national leaders, exercising control over vast digital territories without democratic accountability: "the chief executives of leading tech companies are now by many measures more powerful than most countries' heads of state" (p. 3). All in all, in this situation, "the authorities in charge are not nation states but digital platform companies" (p. 6). Our contention is that the situation is more complex. While platforms have *de facto* acquired functions that were typical prerogatives of the state, they have done so with the consent of their state of incorporation as seen most evidently in the US. Further, the current drive towards a platformization of the state as well as the growing efforts by other world regions other than the US, to recuperate some degree of digital sovereignty (Pohle and Thiel, 2020), may well be seen as a pathway to recuperate state capacity by means of digital technology, as we shall expound in the ensuing section.

4. Infrastructural power as the logic of the platform state

Both the state and digital platforms, in their respective domains, establish foundational infrastructures and create conditions that allow various stakeholders—citizens and other institutions in the case of the state, and users and complementors in the case of digital platforms—to engage in productive, value-generating activities. Examining this analogy helps clarify the role of government as a "platform provider," as described by Tim O'Reilly (2011). Both states and platforms create incentives and opportunities for external entities to contribute value. In the case of the state, infrastructure investments in areas like transportation and communication lay the groundwork for private sector growth. Roads enable businesses to operate across regions, and public data sets, like those from the National Weather Service, become critical resources that drive innovation in weather forecasting, logistics, and beyond. Similarly, digital platforms provide APIs, developer tools, and marketplaces that enable entrepreneurs to create apps, content, and products, effectively expanding the platform's value and reach.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

For instance, platforms like Apple's App Store allow developers to create applications that enhance the iPhone's functionality, expanding the ecosystem and, in turn, increasing the device's appeal to users.

Much like roads, power grids, and other state-built infrastructure facilitate economic activity, platforms create indispensable digital infrastructures—cloud computing, app ecosystems, and marketplaces—that shape how businesses and individuals interact and create dependencies that resemble those between citizens and state infrastructure. As Morgan Ricks and colleagues argued in their fundamental treaty on networks, platforms and utilities by quoting Felix Frankfurter (1930), the services provided by platform enterprises are "as truly public services as the traditional governmental functions of police and justice" (Ricks et al, 2022). A second analogy can be drawn by building on the work of the legal scholar Julie Cohen (2019). Global platforms can be seen as international actors in their own rights besides other states not only because of their global reach but also because they have an authority, a population, and a territory with clearly demarcated spaces. The territory produced by digital platforms is of course not a contiguous physical space but that is instead is designed via the software architecture and defined using protocols, data flows, algorithms, and can be reprogrammed. Cohen sees the platform authority as 'network power' as well as the 'power to create networks' that originate from a combination of legal documents such as terms of services (ToS) and the control of the software infrastructure.

Ultimately, it is the platform that enforces the decisions via its infrastructure by reprogramming the code and the interface. Some examples in the realm of social media platforms include accounts suspensions and shadow-banning; in the case of delivery platforms, prioritizing those platform workers that stick to their parameters (Aloisi & De Stefano 2022); in the case of the Amazon marketplace, that of giving relevance to vendors (Khan, 2018). This view of the platform as analogous to the legal order of the state can lead us to approach the platform as an organizational logic which exercises its power over a population and a territory (Sassen 2006; Foucault, 2007). However, if the population of a certain state implies citizenships and humans are considered subjects in the sense that they are subjected to the law of the state, the platform ecosystem is instead constituted by the status of users. The distinction between the two is crucial, because a user is not a juridical entity, but a position within a system, so that the relations of those users are organized and orchestrated cybernetically via standards and protocols.

Here the parallel with the core innovations of the platform model is evident. Today, there are approximately 6.5 billion smartphones worldwide, produced and controlled primarily by two American companies—Apple and Google. These companies not only dominate smartphone production but also hold a monopoly over their respective app stores, levying a 30% tax on every transaction. Like the state, platform marketplaces not only allow direct 'taxation' and capture of value production at source, but they also imply a large visibility of the behavior of users and their choices, and they act to modify that behavior (Zuboff 2019). Moreover, similarly to the postal address, the platform reach extends to the IP address of the users (Bratton 2015).

As for identification practices, nowadays, all the main platforms facilitate digital identification, enabling users to log in seamlessly across services, echoing the state's efforts to extend infrastructural power through efficient, centralized identification. This centralized control over digital identities allows platforms to verify users, track behaviors, and link activities across different services, much as states track citizens' movements, credentials, and records across various domains. With single sign-on systems, platforms establish themselves as identity providers, exerting influence over users' access to the broader digital landscape. The analogy between the infrastructural power of platforms and that of the state reveals how platforms exercise control over digital spaces much like states regulate physical territories. Just as states use taxation, identification, and surveillance to manage and shape society, platforms use data collection, digital identities, and algorithmic oversight to control user behavior and extract value within their ecosystems.

In this light, platforms wield a new form of infrastructural power— pervasive and deeply integrated into users' lives—that resembles the power traditionally exercised by states. This parallel raises questions about accountability, sovereignty, and public welfare, as platforms become quasi-state actors in the digital domain. This point is shared by Kelton and colleagues (2022), who analyzed the reach of the infrastructural power of private digital platforms in the United States. They claimed that digital platforms acquired powers across the virtual territories by exercising aspects of infrastructural power defined previously as the prerogative of the sovereign territorial state. Building on the work of Weiss and Thurbon, they claim that there are two components of infrastructural power. First, 'extractive power' (what we have called taxation of the ecosystem), which is the 'capacity to permeate society, and extract and deploy resources with social consent and legitimacy'. Second, 'transformative power', which is the capacity to initiate, sponsor and harness substantial technological innovation for state benefit. According to the authors, we are witnessing another 'social contract' between users and private platforms that challenges the social contract between citizens and the state.

Kelton and colleagues conceptualize this shift in terms of 'virtual sovereignty'. While we can question whether we should speak of virtual sovereignty or instead of platform sovereignty, as perhaps is more adequate, what is apparent is that what is at stake here indeed is a new form of sovereignty, a new form of control over population and territory. Regardless of the difference in terminology, what matters is that the platformization of the state carries with it itself. Digital platforms have essentially acquired an infrastructural power that was previously typical of the state and a practical exercise of its condition of sovereignty.

5. Case studies of the platform state: Italy, France and Estonia

Having explored how global digital platforms exhibit a form of infrastructural power traditionally associated with the state, this section focuses on the concept of the platform state. As a historical manifestation of state governance, the platform state is best understood as a theoretical abstraction. However, its characteristics should also be rooted in the tangible platformization processes of public administrations worldwide. To this end, we compare patterns of state platformization across diverse contexts, including Estonia, Italy, France and India. Despite the vast social, political, economic, and cultural differences among these countries, we argue that their efforts to platformize public administration are based on common principles and promise to deliver similar results. In particular, the platform state promises to increase the legibility of citizens, regain infrastructural power and enable the creation of what might be called 'welfare ecosystems'. In this framework, the concept of the platform state serves as a unifying lens to bundle together the multiplicity of terms used to describe the digitization of public administrations, such as e-government (Jaeger, 2002), one-stop government, and open government (Cordella, 2019). In what follows we shall see how some of these tendencies apply to different European countries that have engaged in programmes of digital transformation of their governments.

5.1 The Italian case: connecting public institutions

Over the last ten years, the Italian government has put forward many projects that incarnate the idea of Government as a Platform (Gaap) with the aim of improving the services offered to citizens and businesses by simplifying administrative action. Three main interconnected 'enabling platforms' have been developed to allow individual public administrations bodies to log in into a shared software that enables them to perform foreseen actions. The three platforms are the 'SPID' (*Public Digital Identity Service*) as the national identification system; second, 'PagoPA', an electronic system that allows citizens and businesses to make standardized payments to public bodies; third, the app of public services 'AppIO' as a single access point for public services that allows to make requests, download documents and can that send push notifications to users (for example, when a deadline for payments is approaching of the ID document is expiring) (Esposito, 2024).

In a true platform fashion, this centralized approach is complemented by The Developers Italia (DevIt) and Designers Italia (DesIt) initiatives. These projects aim to standardize and modernize public administration (PA) digital services. DesIt focuses on spreading a design culture in the PA by providing practical tools, including guidelines, templates, and UX/UI kits, to create inclusive, accessible, and citizen-centered digital services. It supports smaller PAs with limited resources by offering standardized website templates and service archetypes aligned with national regulations. DevIt complements this effort by equipping IT developers with open-source software, libraries, and documentation to integrate enabling platforms and reduce development time and risks. Both projects promote collaboration and resource-sharing through platforms like Docs Italia, Forum Italia, and GitHub Italia, advancing a unified and consistent digital transformation framework across the Italian state. (Esposito 2024)

According to Cordella and Paletti, the Italian case of platformization of public administration enhances the efficiency of public services by reducing silos and avoiding duplication of core functionalities. This approach enables services to evolve more seamlessly and facilitates the integration of interdependencies between different service provisions, allowing for improvements and new service offerings. By adopting the GaaP model, public agencies can achieve better coordination, delivering greater value to citizens without requiring additional resources. However, this shift also redefines the operational capabilities of public administration, reshaping its organizational structure and capacity to create and deliver public services, ultimately transforming how public value is generated (Cordella & Paletti, 2019).

5.2 The French case: renovating administrative relationships

In France, the concept of the "platform state" has sparked significant debate following the publication of O'Reilly's article on government as a platform. Nicolas Colin and Henri Verdier introduced this debate in France envisioning a future where digital platforms revolutionize public service delivery:

> Imagine that 100 applications offer taxpayers different interfaces and innovative experiences for declaring their income and paying taxes online. [...] Imagine that 100 applications combine resources from distinct administrations to provide a unified service integrating multiple functions: declaring a birth, enrolling a child in school, scheduling a hospital appointment, or filing a police report. Imagine these same services blending with others unrelated to administration: being able to shop for groceries, share opinions on movies or books, and, within the same application, request housing assistance from the family benefits office (Colin & Verdier, 2018, 250-251).

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

France has emerged as a focal point for this discussion due to its distinctive administrative tradition and the active involvement of public authorities. In tracing the development of the debate of the platform state in France, Jeannot (2020) reported that the expression was first used in 2014 within the public administration in relation with the project FranceConnect. It was then discussed in a series of report produced by public institutions such as the *Conseil d'État* (2017) in a report on public power and digital platforms, as well as by public authorities like then-Minister Franck Riester (2011) and the *Cour des Comptes* (2018). Overall, these reports have advocated for an interventionist role for the state in developing public services inspired by the innovations of private platforms. These discussions extend to related topics, such as open data and open government, underscoring the complex transformation of public administration.

Jacques Chevallier (2018) describes the platform state as a strategy for a global transformation of the administration and public services, a paradigm shift from traditional bureaucratic systems to more agile, horizontally integrated platforms, fostering citizen co-production and administrative efficiency. Chevallier emphasizes how digital tools, data sharing, and Application Programming Interfaces (APIs) are central to this transformation. Pauline Turk (2020) examined the platform state through the lens of public law, arguing that its core objective is to pursue a form of voluntaristic politics grounded in pragmatic realism. This approach reflects an ambition to adapt the state's role to the challenges of contemporary governance while maintaining its commitment to delivering efficient, high-quality public services. Central to this vision is the transformation of the state from a direct provider of services to an enabler of service delivery through the development and maintenance of critical infrastructure. The state is operating like a platform insofar as its primary function becomes the facilitation and coordination of various actors—public, private, and civil society—in delivering services. Rather than relying on traditional, hierarchical methods of administration, the state adopts a model of outsourcing that leverages digital tools and technologies to optimize service delivery. According to Turk, this marks a profound mutation in the state's role, signaling a move away from direct intervention toward a platform-oriented governance model that prioritizes flexibility, efficiency, and citizen-centric solutions.

The case of FranceConnect serves as a prominent example of France's platformization. As Alauzen (2019) ethnographic research explains, FranceConnect operates as a decentralized authentication system based on the OpenID Connect protocol, which enables secure and interoperable digital identity management. Its architecture is designed to allow users visiting a government website to choose between using a local account or logging in through FranceConnect, providing a unified, streamlined experience across various public services, simplifying administrative processes for citizens. The system also exemplifies the concept of digital sovereignty, as emphasized by its developers. In interviews, the technical director of the FranceConnect project described it as "like Facebook, but it's the state," highlighting its role as a state-owned alternative to commercial platforms (Alauzen, 2019). A defining feature of FranceConnect is its decentralized design, which ensures that there is no centralized database where all public administration data converges. Instead, data remains distributed across the respective administrative entities, with FranceConnect as a facilitator of secure interactions. This approach underscores the importance of ensuring that French citizens authenticate with public services via a government-controlled system rather than relying on private platforms.

5.4 The Estonian case: a borderless state-based platform

Another prominent case of platform state is that of Estonia. Even if the process of platformization of Estonia was developed before and independently from the 'platform state' concept, its case is widely quoted as the cornerstone example of government as a platform and of a proactive approach to the digitization of the public administration. This transformation is particularly significant given Estonia's historical context: following its independence in 1992, the country transitioned from a centrally planned economy to a market-based system, becoming a model of innovative public administration grounded in principles of openness, simplicity, and citizen participation (Espinosa, 2024).

For our purposes, what matters is that the Estonian government developed a three-tiered platform architecture to support its digital ecosystem. At the core lies X-Road, with registries and a data exchange system that enables seamless data sharing departments and agencies.By 2016, X-Road enabled interoperability across 1,700 services and 900 organizations, processing over 500 million transactions annually and more than 1 million requests per day (Margetts & Naumann, 2017). The second tier is a universal eID system adopted by over 90% of the population aged 15 and above, ensuring secure identification for public and private services. The final tier consists of a service layer, accessible through portals like eesti.ee, which integrates these systems into a cohesive, user-centric interface. These interconnected layers underpin a wide range of digital services utilized by citizens, professionals, and businesses to interact and conduct transactions with both public and private sectors.The basic infrastructure – X-Road, eID and the official state portal eesti.ee - are managed and developed by the Estonian Information Service Authority, a central agency with about 120 personnel.

.

Tammpuu et al. (2022) expanded the conversation by explicitly applying the platformization framework to analyze the Estonian case, focusing particularly on its e-Residency program. Drawing on interviews conducted with non-Estonian residents, their work investigates how the concept of platformization, typically associated with private-sector platforms, can be adapted to state functions. The researchers highlight how the Estonian government discursively frames e-Residency as a "platform," "gateway," and "one-stop shop" for accessing public and private e-services, particularly for commercial activities. This framing underscores the state's dual role as a service provider and a transactional platform. Tammpuu et al. 's (2022) reveal how Estonia's e-Residency program supports a novel platform-based relationship between the state and individuals. It is transactionality, a hallmark of digital platforms, that now defines the interaction between e-residents and the state. In this sense, the process of platformization can lead to perceive the state as a "market actor" introducing its digital solutions to the global economy but also as a "membership organization" extending its community beyond territorial borders. Through its digital ID infrastructure, e-Residency program, and vision of a "borderless digital state," Estonia exemplifies the transformative potential of platformization in redefining the role of the state and its relationship with territory in the digital age (Tammpuu et al. 2022).

6. Platforming *et impera*

The cases of France, Italy, and Estonia exemplify a broader trend of state platformization, wherein governments seek to become enablers of digital services rather than remain dependent on private platforms ultimately tied to foreign states. It signals how limited is the dominant narrative of a "weak state" in digital times (Owen, 2015; Lehdonvirta, 2022), and how in fact platformization are unlocking new ways for the state to control its territory and population. To develop this discussion, we have shown how a key strategy in this transformation is the utilization of APIs and public digital identification systems, which facilitate the integration of public institutions, enhance interactions between the state and citizens, and move beyond the siloed approach to administration that has historically fragmented governance structures. By adopting a multi-sided logic, akin to private digital platforms, the platform state reconfigures service delivery, replacing traditional bureaucratic models reliant on physical offices and extensive public employment with reprogrammable digital interfaces that optimize administrative functions. At the core of state platformization is automation and the redistribution of administrative labor. Algorithms increasingly streamline bureaucratic processes, reducing the need for manual oversight by public employees, while platforms shift administrative tasks to citizens themselves—whether for tax payments, permit applications, or welfare access.

We can outline two reasons why the platformization of the state is likely to intensify. First, from an evolutionary perspective, the state cannot ignore the organizational advantages provided by the platform model. This is not simply a matter of delivering more efficient and distributed public services while integrating existing institutions; it is also rooted in the technocratic essence of the platform itself. Second, this shift reflects the broader crisis of governance in an era of global complexity. The platform model allows the state to address its overextended capacity by embracing a distributed, recursive structure. It integrates diverse institutions into a unified framework while preserving their autonomy and facilitating dynamic interactions.. The platformization of the state, therefore, is not only a response to technological advances but also an adaptation to the structural pressures of globalized governance. By internalizing the evolutionary logics of the platform model, the state navigates its inherent limitations and continues to evolve in line with the complexities of modern society. This intensification of platform logic reflects both the constraints and possibilities of governing in an interconnected world.

Track 8: Digital Platform Government and Core Public Values

Track Description

The concept of a digital platform government has its origins in initiatives like the UK's GOV.UK and the Obama administration's Open Government Initiative. While no universally accepted definition exists, it is helpful to compare it to related concepts. Unlike e-government, which focuses primarily on digitalizing services, the digital platform government emphasizes process innovation and operates as a public-private partnership service model. It encourages stakeholder participation and leverages intelligent technologies. Both models promote online citizen engagement, but the digital platform government grants citizens a more direct role in decision-making. Its core public values include efficiency, accountability, fairness, participation, collaboration, transparency, reducing the digital divide, and promoting digital equity. The structure of a digital platform government varies based on its objectives and the role of the government. Scholars have proposed various digital platforms aligned with these goals. With this framework in mind, the aim of the track was to gather papers that examine the relationship between digital platform government practices and these core public values.

Abstract. The declining trend of trust in government has received significant attention among scholars in various fields, particularly in efforts to find ways to reverse this decline. This paper investigates the relationship between trust in government and open government data (OGD), through a proposed model that links trust in government and three variables, i.e., citizens' interaction with OGD, citizens perceived benefits of OGD, and perceived effectiveness of OGD. Utilizing the dataset from Pew Research Center's survey on public perceptions of OGD, we test the model using structural equation modeling (SEM). Our findings show that the three variables positively affect trust in government. However, while the three variables are significant, perceived benefits and effectiveness of open government data are more essential determinants of trust than citizens interaction with government data. This study contributes to understanding how open government data initiatives could increase trust in government, by suggesting practical implications. Nevertheless, this study uses 2014 dataset that might not be able to capture changes in society, such political, economic, social, and technological conditions.

Keywords. Open government data, trust in government, structural equation modeling, citizen interaction, perceived benefits, effectiveness

Reseach paper, DOI: https://doi.org/10.59490/dgo.2025.1006

1. Introduction

Citizens' trust in government has received a great deal of attention from scholars in various fields, ranging from political sciences, public administration, information and technology sciences, and social sciences (Meijer et al., 2012). Their concern was mainly due to the declining trend of trust in government. Tolbert and Mossberger (2006) mentioned that this phenomena has been occurred for the past three decades from the 2000s. A quite recent publication issued by Pew Research (2022) confirmed that the highest trust in government was in 1964, with 77% of citizens trusted the U.S. government. Since then, public trust has declined and remained unstable. The average citizen's trust in government has never reached 30% since 2004.

Distrust in government can be seen from three aspects, i.e., distrust in institutional or political systems (Miller,

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

1974), personal aspects, such as political leaders (Citrin, 1974), and the combination of institutional and personal aspects (Christensen & Lægreid, 2005). No matter what aspects citizens might feel skeptical about the government, the declining trust could be seen as a positive and negative indication in a democratic country (Chanley et al., 2000). However, it could also lead to serious implications, especially when citizens opt out of their decisions and refuse to participate in government's programs. Ultimately, it could obstruct the process of elections (Orren, 1997), policymaking, and policy implementation (Chanley et al., 2000).

Various studies were undertaken to investigate the causes of the declining trend in trust in government. Chanley et al. (2000) mentioned some causal factors that led to the changes in trust in government, i.e., national economic factors (Citrin & Green, 1986; Feldman, 1983; Hetherington, 1998; Mansbridge, 1997; Miller & Borrelli, 1991), socio-cultural factors including problems in society (Mansbridge, 1997), or political factors such as war, political scandals, and corruption (Orren, 1997). Chanley et al. concluded that "declining trust in government is a complex phenomenon with multiple potential causes." (2000, p. 240).

Not only understanding the causes, but a vast amount of literature also discusses various efforts to reverse the decline in trust in government. Norris (2001) argued that an open and transparent government is expected to remedy the loss of faith in government. Government reform is considered indispensable (Osborne & Gaebler, 1992; Peters, 2001), where it requires citizen participation to get involved in the political process (Barber, 2003; Dryzek, 1990). Electronic government was deemed a solution offering myriad opportunities for achieving government reforms. E-government makes it possible for the government to deliver more effective services online (West, 2004), improve citizen-government communication, and increase citizens' political participation (Mossberger et al., 2003; Tolbert & Mossberger, 2006). There are a considerable number of publications that investigate the influence of e-government on trust, such as the work of Horsburgh et al. (2011), Parent et al. (2005), Porumbescu (2016), and Welch et al. (2005), where most of them show a positive association between trust in government and e-government.

As e-government has been widely adopted by federal, state, and local government institutions, there is a trigger for government to be more open and transparent regarding their activities and performances. Open government was coined as the continuation of e-government which enables the creation of massive government data, including the availability of government documents on websites (Abu-Shanab, 2015). Open government is expected to increase the transparency of government activities, improve citizen participation, and strengthen citizen-government cooperation (Susha et al., 2015; Wirtz et al., 2018). One of the open government initiatives is open government data (OGD), which refers to any government-related data generated and owned by various government agencies. The government data such as budget, education, health, population, technology development, geographical data, meteorological data, etcetera, which are available and accessible for public to use are part of OGD (Ubaldi, 2013).

While many scholars have studied the influence of e-government and trust in government, relatively few studies discuss the effect of open government data on trust in government. In addition, to my best knowledge, there is no literature discussing the influence of open data in government and e-government services on trust in government. This paper explores the interconnection between citizens' interaction with government data and citizens' trust in government. The article begins with discussing the current state of research by reviewing some existing studies on trust in government associated with e-government and OGD. Subsequently, we deduce the conceptual model and hypotheses based on theoretical concepts. Later, findings are presented where we test the model using structural equation modeling (SEM). We use data collected by Pew Research Center (2015) on American Trends Panel Wave 9 Dataset. Finally, we end this article with discussions and conclusions regarding the research implications and future work.

2. Literature, hypotheses, and model

2.1 Trust in government

Trust is a concept that has been discussed in various domains, such as management, public administration, marketing, psychology, and sociology. However, Castelfranchi and Falcone (2010) stated that trust has no clear-cut definition. Focusing on public administration, Hinnant (2007) analyzed various definitions of trust and came up with the concept of trust seen from two perspectives, i.e., trust as behavior and trust as a belief and/or attitude. As a behavior, trust requires taking risks because of uncertainty due to limitations in acquiring information. As an attitude, trust is related to belief which allows an individual to commit even without full knowledge (Luhmann, 2000). As a belief, trust consists of two different attitudes, i.e., attitudes towards the person or object and attitudes towards a specific situation.

Thomas (1998) defined trust based on three conceptions, i.e., fiduciary, mutual, and social. Fiduciary trust occurs when there are asymmetric relationships between a trustee and a trustor. It stands on the principal-agent theory where the principal has limited control over the performance of its agents, and therefore, there are chances for malfeasance. An example of fiduciary trust is trust in professionals such as patients and doctors, clients, and

lawyers. Mutual trust arises from repeated interactions between a trustee and a trustor. This type of trust is always interpersonal, for example, between students and their teachers as well as citizens and street-level bureaucracy. Social trust emerges as a result of social factors within social systems such as cultures, regulations, ethics, and norms, which restrain individual choices to calculate some options.

With regard to trust in government, fiduciary relationships have long been perceived as an essential component of citizens' trust in government (Barber, 1983; Kass, 1994; Thomas, 1998). Citizens have limited knowledge and ability about what the government is doing and how to control their performance. Therefore, the citizens-government relationship is considered asymmetric. Taking the concept of trust defined by Hinnant (2007), the asymmetric relationship makes the citizens take risks and believe that the government will perform in their interests.

The declining trend in trust in government has attracted the interest of many scholars. Many studies were conducted to investigate the causes of falling, such as Citrin and Green (1986), Feldman (1983), Hetherington (1998), Mansbridge (1997), and Miller and Borrelli (1991). They argue that the national economic factor is the reason why citizens distrust their government. Socio-cultural factors such as societal problems are another determinant (Mansbridge, 1997; Pew Research Center, 1998). Wars, political scandals, and corruption are considered political factors that could undermine trust in government (Orren, 1997). The declining trend is complex due to many possible factors (Chanley et al., 2000).

2.2 Citizen's interaction with government data

As a new concept implemented by government institutions, there is limited research investigating the link between trust in government and open government data. Among these few studies, most of them focus on understanding citizens' trust in open government data (Purwanto et al., 2020) and the intention of citizens in using open government data (Khurshid et al., 2022; Souza et al., 2022; Wirtz et al., 2019). To our best knowledge, the study conducted by Gonzálvez-Gallego et al. (2020) is the only study that directly explores the link between open government data and trust in government. The association was investigated through a mediation role, i.e., citizens' satisfaction, measured based on satisfaction with the economy, government, education, health services, and democracy.

While limited research is found on OGD and trust in government, many studies investigated the influence of e-government on trust in government. Parent et al. (2005) found that citizens' transactions with government services positively affect trust in government and external political efficacy. Their findings confirm that trust in government was influenced by several factors, including the quality of e-government experiences. They measured experiences based on questions related to respondents' activities with online government services. Welch et al. (2005) investigated the link between citizen satisfaction with electronic government services and trust in government. Their findings also showed a positive association between e-government satisfaction and trust in government. Later, Tolbert and Mossberger (2006) also explored the influence of e-government on trust and confidence in government. Their evidence suggests a link between the use of government websites and trust in government. They concluded that e-government has the force to increase trust through interactions with citizens. Other scholars who concentrated on public administration corroborate that trust in public administration is positively associated with the perceived quality of electronic services (Gracia & Casaló Ariño, 2015). They asked respondents about experiences and perceptions about e-government services based on four dimensions of service quality proposed by Parasuraman et al. (2005).

We conclude that according to these studies, the interactions of citizens with government digital services influence trust in government. The more the citizens interact with government digital services, the more they trust in government. Interactions can be in the form of accessing government websites (Tolbert & Mossberger, 2006) and other experiences using e-government services (Gracia & Casaló Ariño, 2015; Parent et al., 2005).

As open government data is part of digital government services, we argue that interactions of citizens with open government data influence trust in government. There are some forms of interactions; access to data is one of them. When citizens access government data, it facilitates the principle of transparency which "allows the citizen to see what the government is doing, and how it is doing it" (O'Hara, 2012, p. 226). It shapes the citizens' perception that their government is accountable for what they are doing, and as a result, their trust in government increases. Therefore, we propose a hypothesis to relate the interaction of citizens with data and trust in government.

H1: Citizen's interaction with government data positively influences citizen trust in government.

2.3 Perceived benefits

The perception of benefits has been seen as a determinant of trust in prior studies in the information systems-related field. E-government and OGD have triggered government institutions to treat information as an asset that

offers tremendous benefits for the government and stakeholders, including citizens. The benefits of OGD for citizens are mainly clustered based on political and social benefits and economic benefits (Janssen et al., 2012; Mokobombang et al., 2019; Safarov et al., 2017).

In terms of political and social benefits, opening government data to the public enables the government to be more transparent. Linders and Wilson (2011) argued that transparency is an anti-corruption mechanism to ensure decision-makers' accountability. Transparency in government data makes it possible for citizens to have equal access to the data, participate in controlling the functioning of government, and ensure that government is accountable to public. OGD also enables citizen participation at various policy cycle stages (Galster, 2018), forcing the government to be more aware of their decision-making process as citizens can always get informed about the government's workings. OGD is thus expected to result in better decisions by government officials. Another benefit is to increase the quality of public services. In their paper, Safarov et al. (2017) noted some publications that focus on the use of OGD to improve public services, for example, citizens apps that make use of OGD to solve urban-related issues such as public transportation, public safety, and public utilities (Desouza & Bhagwatwar, 2012). OGD also brings impacts on public engagement with the government that can lead to trust in the government.

We argue that the benefits of OGD perceived by citizens influence trust in government. In trust-related research, some scholars associate trust with benefits and values. Yang (2005) mentioned two theoretical approaches in trust research, the economic and ethics approach. The economic approach assumes that trust is defined by four assumptions, one of which is the logic of calculations where people see benefits and costs before they trust an entity (Hardin, 2002; Williamson, 1996). Concerning OGD, understanding its benefits can help citizens have a better logical calculation to trust their government. The second approach, the ethics approach, assumes that trust is defined by three assumptions (Baier, 1995; Uslaner, 2002), one of which is social and moral relations. In terms of OGD, citizens will tend to trust in government whenever OGD's benefits are associated with social and moral values. The power of OGD as an anti-corruption tool fits the social and moral values. Therefore, we claim that the perceived benefits of OGD positively influence citizen trust in government.

H2: Citizen's perceived benefits of government data positively influence trust in government.

2.4 Effectiveness

Effectiveness is related to evaluation and usually linked to efficiency. When efficiency is defined as completing tasks with little waste, effectiveness reflects achieving the desired results, outcomes, or effects (Kjurchiski, 2014). Effectiveness is not only about achieving the objectives but also the desired results, outcomes, or impacts. A government program is called effective when the actual results achieve the objectives and produce the intended effects.

There is no publication focusing on the effectiveness of OGD. However, some publications discuss the effectiveness of e-government and general information systems (IS). Wang and Liao (2008) mentioned the effectiveness of information systems as the success of IS. An information system is called effective whenever it successfully achieves the intended outcomes. They argued that measuring the effectiveness of IS means measuring the success of IS. Therefore, they referred to the Information Systems Success Model (ISSM) developed by DeLone and McLean (1992, 2003) to measure the effectiveness of IS. The model consists of six dimensions that explain the success of IS. One of the dimensions associated with the definition of effective is net system benefits, which means the ability of the system to deliver impact or values to users as well as the organization. This dimension is seen as the intended outcomes of information systems, including e-government.

Based on the ISSM, OGD is called effective when citizens perceive and feel that OGD brings net benefits or values for them—not only for their government. Having access to open government data, citizens can experience values, such as more transparent government, equal access to government data, ability to reuse data for other purposes, ability to control government, etcetera. For the government, there is a wide range of benefits such as better service delivery to citizens, good governance, an increase in images, more innovations in society, and so on. Therefore, citizens may respond positively following the disclosure of government data. They might perceive OGD as effective because they could know better what the government is doing. As a result, their trust in government increases.

H3: Citizen's perceived effectiveness regarding open government data positively influences trust in government.

2.5 Model

This paper investigates whether citizens' interaction with government data, perceived benefits, and perceived effectiveness of government data are essential indicators of citizen trust in government. The formula to solve the aim of the paper is as follows. Trust in government is a function that consists of three variables, i.e., `Citizen Interaction`, `Perceived Benefits`, and `Perceived Effectiveness`.

Trust in Government = ƒ (Citizen Interaction, Perceived Benefits, Perceived Effectiveness)

3. Data and methods

We use data from a national survey conducted by Pew Research Center on public opinion, taken from the American Trends Panel Wave 9 Dataset (Pew Research Center, 2014) that was undertaken between November 17 and December 15, 2014. The survey topic was post-election of 2014 and US citizens' views of open data/open government. The sample consists of 3,212 respondents, where 2,856 of them participated in Web surveys, and the other 356 respondents participated through the mail. To ensure the representativeness of the population, the sample was weighted in several steps (Pew Research Center, 2015). The margin of error for the total sample is ± 2.3%. The survey asked respondents to answer 192 questions, including demographic. The survey questions were categorized based on three sections, i.e., the post-election section, open government and open data section, and religious demography section. This paper uses data in the open government and open data section.

We realized that the data used in this study are old because it is from 2014. There have been changes in political situation, federal initiatives, technology advancements, and so on that might also change the public experiences on open government data. However, there are at least two reasons that justify the relevance of the data even today for understanding public opinions towards open government data and trust in government. First, the comprehensiveness and representativeness of the data. The dataset provided by the Pew Research Center is large, with extensive demographic representativeness (as seen in Table 1) and a rigorous methodology, ensuring the reliability of the findings. Second, there is no recent dataset that captures public opinion's data on OGD and trust in government as comprehensive as the American Trends Panel Wave 9 Dataset. To my knowledge, this dataset is the most comprehensive and publicly available data source, notwithstanding its age. In addition to its large sample size, this dataset remains relevant to comprehend the phenomena as described in our research question.

Regarding the demographics of the respondents as seen in Table 1, more female respondents participated in the survey than males, with the percentages of female and male respondents being 52.1% and 47.9%, respectively. Regarding the age distribution of the respondents, most of them were within the range of 50-64 years old (32.7%), 30-49 years old (27.2%), and more than 65 years old (25.4%). Only 14.2% of the respondents belonged to the 18-29 age group. With regards to education, half of the respondents were college graduates. Concerning their race/ethnicity, 77.8% of them were white non-Hispanic (77.8%). Other minorities, i.e., black non-Hispanic, Hispanic, and other races, were counted for 8%, 7.6%, and 5.7%, respectively. Almost all respondents (97.9%) were US citizens. There were more Democrat/Lean Democrat supporters than Republican/Lean Republicans who participated in this survey. The respondents' income concentrated on a yearly income up to $75,000 and around $30,000-$74,999. Regarding Internet use, the demographic result showed that most respondents were Internet users (92.4%).

Tab. 1 - Respondents' demographics

Categories	Percentage (%)
Age	
18-29	14.2
30-49	27.2
50-64	32.7
65+	25.4
Sex	
Male	47.9
Female	52.1

$30,000 - $74,999	35.3
Less than $30,000	23.6
Do not know/refuse to answer	5.4
Household internet status	
Not Internet user	7.6
Internet user	92.4

The dependent variable in the model is `trust in government`. The data are taken from the survey questions about trust in government which consists of three items. This variable is measured by the frequency of trust in federal, state, and local government on a four-point item scale ranging from 1 (just about always) to 4 (none of the time). The independent variables consist of `citizen interaction`, `perceived benefits`, and `perceived effectiveness`. The variable citizen interaction is operationalized as citizens' access to information or data provided by the federal, state, and local governments, as reported in the survey. The operationalization uses a two-point scale (yes and no). The perceived benefits variable is operationalized as the perception of respondents regarding the impacts that open government data has on public. There are five items with a two-point scale (yes and no). The last variable is perceived effectiveness, operationalized as respondents' perception of whether the government is effective in sharing government data with the public. This variable has three items with a four-Likert scale, ranging from 1 (very effectively shares the data it collects) to 4 (not all effectively).

Regarding the methods, we used IBM SPSS Statistics for descriptive analysis and internal consistency. Subsequently, we conducted a study using structural equation modeling (SEM) on IBM SPSS AMOS 27 to find the causal relationships in the hypothesized model. SEM consists of the measurement and structural models (Fan et al., 2016; Kline, 2015). The measurement model determines the relationship between each unobserved or latent variable and its indicators (observed variables), whereas the structural model describes the relationship between the variables or the constructs in the model. The structural model tests the hypothesized model (Kline, 2015).

For the measurement model, whenever the indicators for each unobserved variable are specified based on relevant theories or prior knowledge, confirmatory factor analysis (CFA) is applicable to the use (Brown, 2015; Harrington, 2009; Jöreskog, 1969). Whenever the underlying latent variables are not yet specified because of little knowledge about them, exploratory factor analysis (EFA) is relevant. In this paper, the proposed model has never been introduced before. However, the underlying latent variables are specified based on prior knowledge and models as described in the previous section. Therefore, we use CFA before the structural model to determine whether there is a relationship between the observed variables and their unobserved or latent variables (Child, 1990; Kline, 2015). We use the maximum likelihood (ML) estimation method for the CFA. We continue with the structural model to test the hypothesized model whenever the result is satisfactory.

However, we acknowledge that the operationalization of the constructs used in this study is based on the survey items provided by the Pew Research Center's data rather than purposeful survey instruments built specifically for this study. Both dependent and independent variables are approximated through existing questions in the Pew Research's questionnaires that are closely related to our theoretical foundations. However, even so, the measures provide a meaningful way to investigate the relationships being studied in this paper.

4. Data analysis and findings

4.1 Measurement Model

We use CFA to measure the quality of latent variables by examining the relationship between the latent variables and their indicators or items before we use them in our structural equation model. The first step is to calculate the factor loadings or the correlation coefficient of the indicators that associate with each latent variable to check the convergent validity of our variables or constructs. Figure 1 presents the measurement model, including the standardized factor loadings. As seen in the figure, the values of the factor loadings range from .640 to .930. Most values are above .7, which indicates essential indicators. There are three items with loading factors between .6 to .7. As the cutoff for standardized factor loadings adopted by many scholars is .5 (Fabrigar et al., 1999), these indicators are retained. To sum up, the convergent validity of our variables is good, indicated by high standardized loadings.

Not only checking the convergent validity of the variables and their items, but we also check the discriminant validity by identifying the correlation of each pair of variables in our model. According to Figure 1, there are six

pairs of variables with correlation value lies between .095 and .430. None of them has a correlation value greater than .85—the cutoff used by some researchers to combine two variables due to discriminant validity.

The final step in reviewing the measurement model is checking the goodness of fit statistics to examine whether the model fits with the data. The summary of the fitness indices is presented in Figure 1. When we set the alpha level at .05 with df 71, we get the result that the chi-square is larger than the chi-square of the critical value, and thus, we reject the null hypothesis. It means that the hypothesized model significantly deviates from the observed model. However, chi-square is sensitive to the number of samples. With a large sample size, a researcher tends to get significant results and thus reject the null hypothesis even though the model is good. Therefore, we also use other indices, i.e., RMSEA, CFI, TLI, and SRMR. We follow the cutoff for fitness proposed by Hu and Bentler (Hu & Bentler, 1999). According to Figure 1, the RMSEA (.072) is less than .05, which indicates a good fit. CFI and TLI are .941 and .925, respectively, which both suggest a reasonable fit (.90 to .95). SRMR (.0419) is lower than .08 and therefore considered a good fit. Finally, we conclude that the fitness indices produce satisfactory results, and thus, it is assumed that the hypothesized model is a valid representation of the data or the empirical reality.

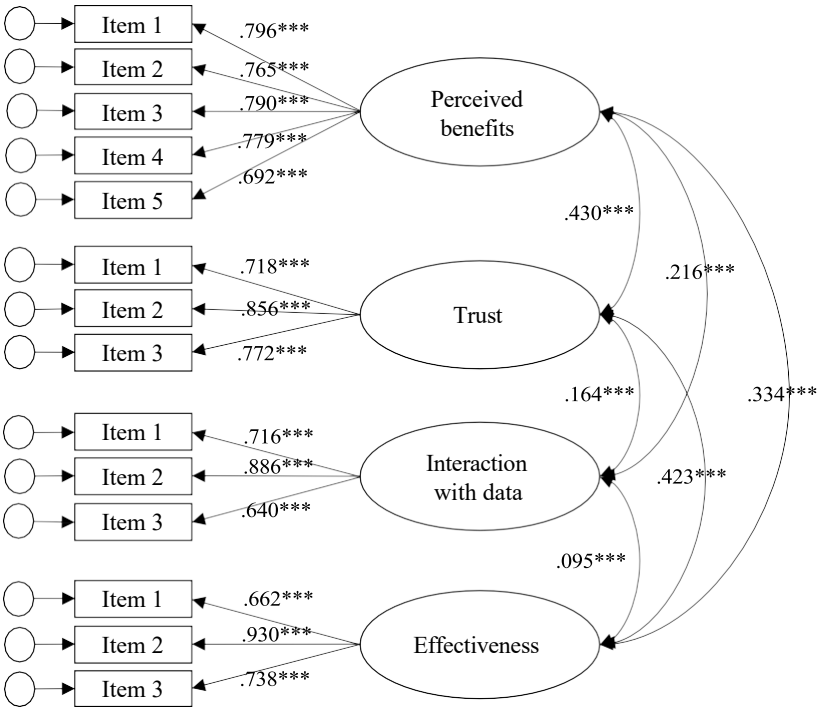

Fig. 1 - The measurement model, including its fit indices

4.2 Structural Model

We summarize the fitness of the model, the path coefficients, and the squared multiple correlations (R^2) in Figure 2 to assess the structural model. The global fit indices indicate a satisfactory fitness of the model because the index meets the cutoff of a good fit. It means the hypothesized model is a good representation of the empirical data.

According to the path coefficients, the three hypotheses are significant; thus, we fail to reject the null hypotheses. The path coefficients confirm the positive and significant impact of perceived benefits, interaction with data, and effectiveness on trust in government. To be more specific, perceived benefits (.312) and effectiveness (.312) appear to be stronger determinants to trust in government, while interaction with data (.067) has relatively lower importance. Altogether, the overall hypothesized model is significant, and the R^2 is .277, which means 27.7% of the variance of trust in government is explained by the three factors, i.e., perceived benefits, interaction with data, and effectiveness.

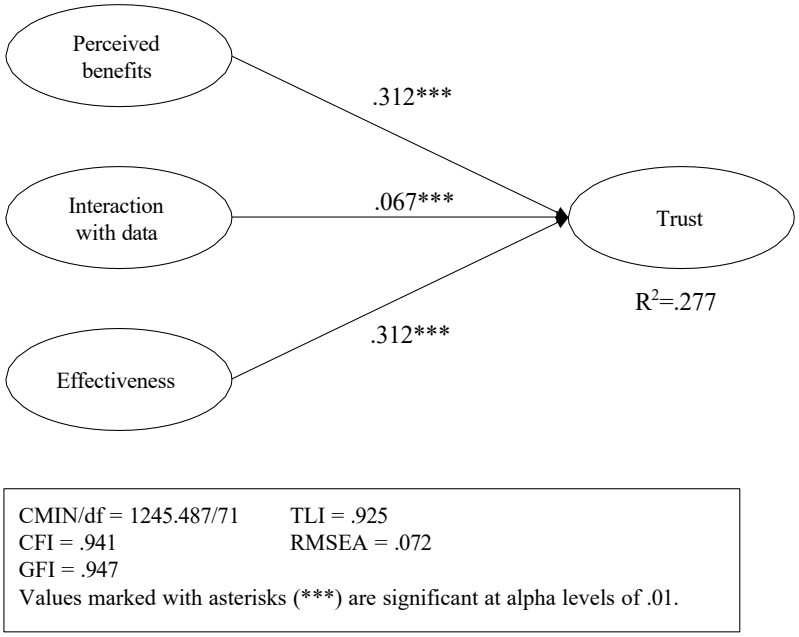

Fig. 2 - The measurement model, including its fit indices

5. Discussion

OGD increases trust in government through citizens' interaction with the data

The findings of this study support previous findings on e-government and trust in government. Our results confirm Parent et al. (2005), Tolbert and Mossberger (2006), and Gracia & Casaló Ariño (2015), who stated that citizens' transactions with government services had a positive association with trust in government. More specifically, they argue that trust in government is influenced by the quality of e-government experiences (Gracia & Casaló Ariño, 2015; Parent et al., 2005) and interaction with government websites (Tolbert & Mossberger, 2006). Our findings validate the importance of these interactions in building trust in government. While prior studies have highlighted the interaction of citizens with e-government, our findings emphasize that open government data can increase trust in government through citizen engagement with the data. Since no prior study investigates interaction with data and trust in government, our study is the first to confirm that citizens' interaction with government data positively influences trust in government.

Moreover, our results also corroborate the literature on the concept of trust. Interaction has long been perceived as a concept that forms trust in public administration. For example, Thomas (1998) states that mutual trust emerges whenever repeated interaction occurs between individuals or entities. Our findings extend the definition of interaction by arguing that even indirect interaction with government data can influence citizens' trust in government.

Perceived benefits of OGD matter for trust in government

Furthermore, perceived benefits play an essential role in improving trust. Our findings support previous studies in information systems literature on the perception of benefits and trust (Catoiu et al., 2014; Park et al., 2019). Focusing on mobile payment, Park et al. (2019) found that the perception of the benefits of using m-payment positively influences the customer's trust in m-payment. Investigating users' trust in online social networks, Catoiu et al. (2014) reported a positive correlation between the user's perceived benefits and trust in online social networks. Our results are consistent with their findings, indicating a positive and significant correlation between perceived usefulness and trust. Although our domains are different, the three findings confirm that the perception of benefits is an essential determinant of trust. Specifically, in the context of trust in government, our findings highlight that perceptions about the benefits of OGD are a significant determinant.

These findings can be explained by the previous trust theory proposed by Yang (2005), who accentuated that individuals are usually triggered by some logical calculations such as benefits and costs before they trust an entity (Hardin, 2002; Williamson, 1996). Our study confirms that this economic logic is relevant in public administration. Before trusting their government, citizens will consider what benefits they can obtain from specific services. Citizens develop perceptions regarding the benefits that they might get. In the context of open government data, where the data can be obtained freely, many benefits of OGD outweigh the costs, and therefore, it brings citizens to trust their government. This argument is also consistent with the statement of Wirtz et al., who states that "… although citizens seem to be blind to external incentives, they strongly take into account the usefulness of open government data, thus suggesting that to some extent their behavior is indeed also guided by "practical rationality,"

and thus underlies instrumental considerations in terms of maximizing their benefit." (Wirtz et al., 2018, p. 315).

Our results also support the assumption that trust is defined by social and moral relations (Baier, 1995; Uslaner, 2002). Based on this assumption, individuals tend to trust other individuals or entities whenever the offered benefits are aligned with their social and moral values. This logic seems plausible in the context of open government data, as its benefits are linked to social values. For example, government data has the power to improve the accountability, transparency, and good decision-making of government, where all of which are associated with responsibility, honesty, integrity, and justice of the government. These values, in turn, inspire citizens to trust their government. As Hinnant (2007) suggests, trust can be seen as an attitude or behavior. We also agree that social values influence citizens' attitudes toward trusting their government, as these values are reflected in the benefits of open government data. Another possible explanation is the asymmetric relationship between citizens and government (Thomas, 1998), where citizens have limited knowledge about what the government is doing. Given this imbalance, it is plausible that after all, citizens rely on social and moral values when deciding to trust their government.

The significance of OGD effectiveness on trust in government

Our findings provide strong evidence that the effectiveness of open government data has a positive correlation with trust in government. Effectiveness is defined as the achievement of the desired results or outcomes (Kjurchiski, 2014). OGD is called effective whenever citizens both perceive and feel that it delivers the results they expect. Our results confirm that trust in government increases whenever citizens recognize that OGD has met their expectations. These expectations are typically related to accountability, transparency, and good decision taken by the government.

Wang and Liao (2008) denoted the effectiveness of information systems as the success of IS. Over the past several years, some studies have been conducted to investigate the success of IS in various domains, including e-government (Rana et al., 2015; Scott et al., 2009) and open government data (Purwanto et al., 2017). However, to date, no study has explicitly looked at the link between the effectiveness of IS or the success of IS and trust in government. Our study bridges the gap, highlighting the connection between research in public administration and information systems.

Practical implications

According to our research findings, we suggest practical implications for public administrators, public managers, and policymakers that could help increase citizens' trust in government through OGD. Considering the importance of perceived benefits, we find it crucial for practitioners to focus on increasing the understanding of the open data benefits for citizens. The objective is not only to inform citizens regarding possible direct benefits when they participate in open government data but also indirect benefits such as transparency, accountability of government, and so on. In the ladder of citizen participation, informing citizens is "the first step toward legitimate citizen participation" (Arnstein, 1969, p. 219).

There are several approaches that the government can do to inform citizens about OGD's benefits. One of which is to improve the relations between government and media, allowing journalists to use government data to report and inform what the government is doing (Papoutsaki, 2008). Citizens favor this indirect benefit, as confirmed in our study, because they believe that OGD enables journalists to cover government actions in greater detail. Another essential approach is to focus on creating informed and engaged citizens. Milner (2002) stated civic literacy is vital to developing informed citizenship. Creating informed citizens can be done through the collaboration between government and community.

Our finding validates the significance of citizens' interaction with open government data. Thus, a practical implication for the government is to increase the availability of government data and information for public to access and utilize the data. This means that data must be free, available, and accessible for citizens in a standardized format, following the principles of open data. Wirtz et al. (2018) also mentioned that government websites and online platforms used to present the open data must align with citizens' needs, stressing the necessity to design the platforms with usability in mind. By focusing on making more government data accessible to citizens and improving the usability of the online platforms, the government can increase the effectiveness of OGD and ultimately, strengthen citizens' trust in government.

6. Conclusion

This paper aims to investigate the connection between trust in government and three factors, i.e., the interaction of citizens with government data, the perception of benefits of government data, and the effectiveness of government data. Our findings show that citizens' interaction with OGD matters in increasing trust in government. Specifically, the more citizens interact with open government data, the greater their trust in the government. This finding aligns with previous studies in the e-government domain, for example, the work of Parent et al. (2005), Tolbert and Mossberger (2006), and Gracia & Casaló Ariño (2015). Our findings also strengthen the concept of

trust proposed by Thomas (1998), who states that repeated interaction between individuals and entities can create trust.

However, our results indicate that perceived benefits and effectiveness of government data are more essential determinants than citizens interaction with government data. When citizens have a better perception of the benefits of open government data, they tend to trust their government. Therefore, we conclude that government needs to focus on informing citizens about the values of open government data, both direct and indirect benefits. Another important determinant is the effectiveness of OGD. The findings also reveal that the effectiveness of open government data has a positive correlation with trust in government, meaning that when citizens both understand the benefits of OGD and also feel that it delivers their desired expectation, they will tend to trust their government.

Our study has some limitations, especially concerning the data and the questionnaire. First, the data used were taken in 2014. Even though the sample size is enormous, there might be cases where there are some changes in society, such as political, economic, social, and technological conditions. These changes could result in different responses and, thus, different results whenever the same study is conducted using more recent data. We recommend conducting a similar study using more recent data to test the consistency of the results. Second, this study uses existing data provided by Pew Research Center (2014). As a result, the number of items asked in the questionnaire cannot be adjusted according to our needs. For example, there are many types of interactions, but this study only considers the first interaction level, i.e., data access. The number of items for each factor is also limited as we used the Pew Research Center's data. Using the same model to test trust in government, we recommend having a more thorough instrument that includes more items. We also recommend testing the same model in the context of OGD outside the United States to know whether trust in government in other countries is positively influenced by perceived benefits, effectiveness, and interaction with open government data. Third, there is a possibility of reverse causality, meaning that there is a chance that high trust in government might lead to more interaction with government data. This phenomenon has not yet explored in this study. Finally, we recognize that the model of trust in government used in study is notably like the constructs used in technology acceptance, especially the Technology Adoption Model (TAM) (Davis, 1989). This overlap could further be explored to investigate the intersection between trust in government and technology acceptance in the context of open government data. This investigation could provide insights into how public acceptance on open government data influences their trust in government. Therefore, future study to extend the model is worth investigating to enrich the literature of both technology acceptance and trust in government.

Abstract. The paper presents the Brazilian Public Audiovisual Content Platform, an initiative by the Ministry of Culture that aims to democratize access to national audiovisual content, with a focus on cultural inclusion and diversity. The platform complies with Law 13.006/2014, which mandates the screening of national films in schools and adopts the principles of Digital Government as established by Law 14.129/2021, prioritizing citizen-centricity, social participation, interoperability, and integration with other public services. The study employed an exploratory evaluation, supported by a qualitative approach, for collecting and analyzing primary data. The research methodology incorporated document analysis, pilot testing, and representative groups from the platform's user base. Data collection initially involved reviewing official documents, including the Work Plan approved by the Ministry of Culture, compliance reports, public policy documents, and legislation related to Digital Government. The analysis highlights technological challenges such as data security and accessibility, as well as the need to reduce digital exclusion. It concludes that the platform represents progress toward building a more inclusive and transparent digital government, with the potential to inform future public policies in the cultural and digital domains.

Keywords. Digital Platform Government; Brazilian Audiovisual Content; fairness, democratization
Policy paper, DOI: https://doi.org/10.59490/dgo.2025.1050

1. Introduction

Democratizing access to culture is a historic challenge in countries with significant social, cultural, and regional diversity, such as Brazil. Inequality in access to cultural goods is exacerbated by economic, geographical, and technological barriers, limiting the ability of millions of citizens to participate in and enjoy cultural expressions

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

[13]. Cultural democratization policies play a crucial role in expanding the distribution of cultural goods and increasing access to cultural institutions and public spaces [4].

Culture is a crucial structural component for the development of society and its subsequent social transformation [12]. Brazil's Federal Constitution of 1988 establishes that the State must guarantee the whole exercise of cultural rights, facilitate access to sources of national culture, and promote the appreciation and dissemination of cultural expressions [2]. In this sense, cultural policies play a strategic role in ensuring social inclusion and cultural citizenship, promoting diversity of expression, and encouraging access to cultural productions across multiple platforms [12].

In this context, the Brazilian Ministry of Culture (MinC) proposes the development of a Public Platform for Brazilian Audiovisual Content as a strategy to democratize access to national audiovisual production and promote cultural inclusion through diverse audiovisual content, representing different languages, formats, and aesthetics, with special attention to issues of gender, race, and accessibility. The platform is also targeted at schools to comply with Law 13.006/2014, which requires the screening of nationally produced films in elementary and secondary education schools, as well as the use of non-commercial cultural dissemination spaces.

The platform is under development through a partnership between the Secretariat of Audiovisual of the Ministry of Culture (SAV/MinC) and the Center for Excellence in Social Technologies (NEES), linked to the Institute of Computing (IC) of the Federal University of Alagoas (UFAL) through a consultancy hired by the Organization of Ibero-American States (OEI) [10]. This collaboration enabled the development of a digital platform that not only meets the needs of public access to Brazilian audiovisual content but also incorporates the guidelines and principles of the Digital Platform Government.

This article proposes a public platform aligned with the principles of the Digital Platform Government, aiming to promote the democratization of Brazilian audiovisual content. To this end, it seeks to fulfill three specific objectives: (1) examine citizen-centricity and user experience; (2) discuss social participation and collaboration; and (3) identify possibilities for interoperability and integration with other services.

From a theoretical standpoint, it is essential to emphasize that, within the Brazilian context, a significant gap exists regarding unequal access to culture as a historical challenge. In this regard, investigating how digital platforms can foster cultural inclusion contributes to understanding how digital public policies can directly impact the democratization of cultural access, a key issue in theories addressing social justice, equal access, and digital inclusion. In terms of the challenges to be addressed, the platform-based governance model can foster practices of public collaboration, transparency, and social inclusion in a country with continental dimensions and significant social inequalities.

Concerning practical implications, the research proposes a discussion on democratizing access to governmental digital platforms as an effective means to overcome historical challenges related to the unequal distribution of cultural goods. Furthermore, the research could serve as a reference for other digital governance initiatives that seek to promote inclusion and equity in access to culture, particularly in terms of accessibility needs and the integration of cultural content, while also promoting transparency, collaboration, and interoperability in the face of digital fragmentation, as well as challenges related to data security and universal internet access.

The article's structure is as follows: The following section contextualizes the concept of Digital Platform Government, highlighting its main characteristics and fundamental role in cultural democratization and digital inclusion. The following is the research methodology. Next, the results and discussion are presented, focusing on specific objectives. Finally, the platform's contributions to strengthening cultural inclusion and digital governance are discussed, highlighting technological challenges and offering support for improving public policies and future strategies that aim to expand access to culture in the digital environment.

2. Background

Public administration needs a solid structure to guarantee the adequate provision of public services. In an increasingly connected society, it is essential to develop mechanisms that optimize public management and align government action with the emerging demands of the digital world [6]. With the advancement of Information and Communication Technologies (ICTs), governments around the world have adopted digital solutions to improve service delivery and facilitate interaction with their societies.

Just as in the private sector, the modernization of public administration seeks to establish a new paradigm of action, making processes more agile, less bureaucratic, and citizen-oriented. The creation of digital government platforms has been a key driver of this transformation, providing greater accessibility and efficiency in public management. In this context, the concept of Digital Government has emerged, an approach that aims to integrate technological solutions into state administration, promoting the interoperability of systems, the centralization of services, and

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

citizen participation [5].

The digitization of public services not only makes it possible to expand access to cultural goods but also to promote more inclusive and transparent management. In the cultural field, the application of these principles has made it possible to create initiatives such as the Public Platform for Brazilian Audiovisual Content, which seeks to facilitate access to national audiovisual production and promote cultural diversity through an accessible and interoperable technological solution. In this way, the adoption of digital platforms in government cultural management represents a significant advance in democratizing culture and ensuring fair access to Brazilian audiovisual content nationwide.

2.1 Digital Platform Government

The Digital Platform Government is an innovative model that cuts red tape in administrative processes and modernizes public services through the intensive use of digital technologies. The model emphasizes process innovation, operates as a public-private partnership, and encourages stakeholder participation. It also leverages innovative technologies and ensures transparency in managing public data [5, 11].

The core values of this model include efficiency, accountability, fairness, participation, collaboration, transparency, reducing the digital divide, and promoting digital equity. Its structure varies according to the government's objectives and role, and it is adaptable to different institutional and technological contexts. The literature already proposes various types of digital platforms and explores and applies them in multiple areas of the public sector [6].

In Brazil, Law No. 14.129/2021 (Digital Government Law) formalizes the digital modification of Public Administration, expanding citizen participation and encouraging innovation in public services. The legislation establishes essential guidelines for building digital platforms that guarantee accessibility, security, transparency, and interoperability between government systems [5].

In this way, the Digital Platform Government shows excellent potential in modernizing and expanding access to cultural goods. By integrating these principles into initiatives like the Public Platform for Brazilian Audiovisual Content, the goal is to ensure the democratization of access to digital culture, allowing citizens not only to consume but also to participate in cultural and audiovisual production actively. To this end, it must maintain as its central axes: (1) the satisfaction of a growing set of demands from society; (2) the openness and transparency of data; (3) the wide distribution of services; (4) the use of clear and accessible language as a way of communicating and getting closer to citizens; (5) the prioritization of public services in digital format; (6) the guarantee of security and privacy of citizens' sensitive data; (7) the promotion of social participation. In short, the Digital Government must act as an open and inclusive platform focused on the country's socioeconomic development and technological advancement, intending to continuously expand and optimize the quality and reach of public services [6].

2.2 Inclusion and Cultural Democracy

Equal access to and participation in cultural life have gained prominence in national and international discussions. Guaranteeing the active involvement of civil society acts as a catalyst for social inclusion [15]. Social inclusion is the active participation of civil society based on respect for cultural plurality and the value of individual diversity [7].

This emphasis on equal access and cultural participation fosters social inclusion and underpins true cultural democracy. In this scenario, the creation and circulation of cultural goods must be accompanied by a guarantee of their accessibility to diverse audiences, ensuring that inclusion becomes a central principle throughout the cultural process [14].

In recent decades, democratic societies have gradually promoted inclusion as a universal right, guaranteeing access for all to various social spaces. In Brazil, this movement gained momentum after the 1988 Federal Constitution, which established legal and regulatory provisions to ensure accessibility, especially in leisure and cultural areas. Although still in the early stages, cinemas, theaters, museums, parks, and other venues have been designed or adapted to meet the needs of people with disabilities, reducing obstacles and promoting their full participation in cultural and social activities [7]. This progress represents a continuous effort to ensure social inclusion and equal access to essential spaces for human and cultural development.

In short, education, culture, and leisure play crucial roles as structured spaces that have a fundamental power to mediate social inclusion, not just for people with disabilities but for all individuals [7]. In this scenario, digital transformation has created new opportunities for cultural inclusion, allowing more people to access cultural goods through digital platforms. However, there are also challenges, such as the risk of digital exclusion, as well as the need for public policies that guarantee connectivity and full accessibility for all [14]. In this context, the development of a Public Platform for Brazilian Audiovisual Content represents a significant step forward in

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

promoting digital equity and cultural inclusion, making access to audiovisual productions more democratic and affordable.

3. Research Methodology

The results from the exploratory evaluation were consolidated with the support of a qualitative approach to collecting and analyzing primary data. The research was conducted using a combination of document analysis, pilot tests, and representative user groups on the platform.

Initially, data collection involved reviewing official documents, such as the Work Plan approved by the Ministry of Culture, as well as compliance reports, public policy documents, and legislation related to Digital Government (Law No. 14,129/2021).
In terms of the specific objectives of the pilot, these were outlined in both technical and political terms, namely: a) To extract data and reference indicators regarding the reception of the target audience and their experience with the use of the social technology, and; b) To technically test the performance, usability, accessibility, communicability, and load support.

The first phase of the pilot involved identifying the sample, creating a target audience list composed of 30 federal government employees selected by the Ministries of Culture, Education, Science and Technology, and Justice, as well as Secretaries linked to these entities. In the second phase, participants were encouraged to explore the platform autonomously, with 15 days of free access to independently experiment with its functionalities. In the final phase, focus groups were used to gather data on the audience's reception and experience with the technology, focusing on usability, accessibility, and other technical aspects such as performance and load support.

4. Results and Discussions

This section presents the results of this work by discussing the general and specific objectives.

4.1 Public Brazilian Audiovisual Content Platform

The platform is characterized by its principle of free and democratic access. It allows any individual, regardless of their location or socioeconomic status, to access a wide range of audiovisual materials, including short films, feature films, documentaries, animations, and video art.

The Public Platform for Brazilian Audiovisual Content aims to develop and launch a platform that will make audiovisual productions from Brazilian producers available. The platform offers an open and accessible digital space where filmmakers, TV and video directors, video artists, producers, students, enthusiasts, and the general public can share, watch, and explore a wide variety of national audiovisual content, such as fiction, nonfiction, information, entertainment, education, science, and the arts [9].

The platform is characterized by its principle of free and democratic access, allowing any individual, regardless of their location or socioeconomic status, to access a wide range of audiovisual materials, including short and feature films, documentaries, animations, and video art. Another fundamental aspect is the promotion of cultural and creative diversity in Brazilian audiovisuals, ensuring the representation of different languages, formats, and aesthetics, as well as the recognition of various social identities, with a focus on issues such as social class, gender, and ethnicity. The platform also seeks, based on equity, to ensure visibility for regional and local productions, offering a space for expression for young, independent creators and filmmakers, and encouraging the discovery of new talents and innovative projects [9].

4.2 Citizen Centricity and User Experience

Citizens' full adherence to Digital Platform Government models requires the creation of an infrastructure that goes beyond simple internet access to devices. Digital inclusion must follow measures that ensure digital literacy, accessibility, and data protection for citizens [6]. Given this, there is a need for detailed regulations that ensure concrete conditions for the realization of fundamental rights in the digital environment, considering the growing digital presence of the population [3]. Furthermore, the construction of a citizen-focused government involves creating an interoperable system for personal data, as recommended by Brazilian Law 14,129/2021 (Digital Government Law), aiming to ensure transparency and effectiveness in the use of government digital platforms [5].

Given this scenario, the Brazilian Public Audiovisual Content Platform adopts the principle of citizen-centricity, promoting an accessible, personalized, and intuitive digital experience. The platform's design prioritizes digital accessibility, providing audiovisual content adapted to different audiences. This platform includes three levels of adaptation: subtitles, descriptive subtitles, and interpretation in Brazilian Sign Language (Libras), ensuring that people with disabilities can fully enjoy the available content.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

In addition to accessibility, the platform incorporates user experience personalization tools, allowing each individual to tailor their interaction to their needs and preferences, always in line with the best practices of leading content platforms on the market. Among the features offered are browsing history, personalized playlists, the selection of display preferences, and control over subtitles and audio, allowing users to create a digital environment that best suits their needs [5].

The platform's interface was designed with a focus on usability, ensuring an intuitive and fluid experience. Content organization facilitates navigation and allows users to find desired productions quickly. Responsive design ensures compatibility with different devices, increasing accessibility and convenience for different audiences [6].

Participants highlighted the positive aspects of the platform, commending its attractive and intuitive design, which makes navigation easy. Some points for improvement were identified regarding usability, such as difficulty navigating in full-screen mode and the need to refresh the page when entering an incorrect PIN, which made the initial experience confusing. Issues with filter navigation were also reported, with the suggestion to display the combination of active filters on the screen. Furthermore, the "Continue Watching" feature and "Top 10" options appearing on every page can be confusing, leading to the recommendation that they should be displayed only on the main page. Participants also pointed out challenges, such as difficulty locating films with audio descriptions and the lack of optional subtitles.

The platform undergoes continuous evaluations involving accessibility analyses, a review of functionalities and technical requirements, and pilot tests with representative groups of the target audience. These initiatives ensure that the service meets the population's actual demands and can continually evolve to promote a genuinely inclusive and efficient digital experience.

4.3 Participation and Social Collaboration

The digital governance policy in Brazil is based on principles that aim to enhance the provision of public services and strengthen citizen participation. Among these principles, the following stand out: centrality in societal needs, ensuring that government actions and services effectively meet the population’s demands; transparency and open data, promoting access to information and social oversight; infrastructure and service capacity sharing among different governmental bodies; and process simplification to facilitate public access to government services. Additionally, the policy prioritizes digital service delivery, ensuring the security and privacy of citizens’ data. Social participation is also established as a central pillar, promoting government as an open platform dedicated to technological and socio-economic development, with continuous investments in innovation to improve public administration [8].

To promote social participation and collaboration in developing the Public Platform for Brazilian Audiovisual Content, the Ministry of Culture launched a public call for selecting audiovisual content to be licensed and added to the platform’s catalog. This initiative aims to integrate more than 400 completed audiovisual works, allow for their public exhibition, and expand access to national audiovisual production [1]. It also aims to ensure greater diversity and representation, including productions from different regions of the country and independent filmmakers.

Implementing pilot tests during the platform's development is a crucial aspect of enhancing social participation. These tests evaluate the user experience, identifying challenges and opportunities for improving navigation and content accessibility. Collecting user feedback enables technical adjustments and refinements, promoting digital inclusion and ensuring that the platform is genuinely accessible and responsive to users' needs.

Moreover, the platform aims to encourage civil society engagement through participatory tools, including discussion forums, surveys, and collaborative spaces for suggestions and improvements. These functionalities contribute to creating a dynamic and inclusive environment where users can not only consume content but also actively participate in curating and continuously developing it.

4.4 Interoperability and Integration with Other Services

Government digital platforms offer both structural and operational advantages, making them essential for modernizing public administration. Among these advantages, their modularity, adaptability, and scalability are particularly notable. These aspects allow the services provided to evolve as new social and technological demands emerge. Additionally, interoperability between different government systems is a crucial factor in ensuring efficiency and service centralization in a unified, accessible, and secure environment.

The use of open-source software, open standards, and accessible data facilitates interoperability between platforms. This approach makes information exchange between public entities easier and promotes transparency in the sharing of data. It also enhances digital security by allowing different services to integrate modern

technological solutions, such as blockchain, to ensure the authenticity and protection of governmental records and information [11].

Interoperability is a key aspect of the Public Platform for Brazilian Audiovisual Content. In addition to offering public and free audiovisual content streaming functionality, the platform provides a centralized space for promoting the national audiovisual sector. This space aggregates multiple sources of information, including other streaming platforms (both public and private), cinema programming, film criticism, research portals, and initiatives focused on the relationship between cinema and education, offering courses related to national audiovisual production. This integration seeks to connect the various stakeholders in the audiovisual production chain, increasing their visibility and fostering a supportive environment for national culture.

Preliminary analysis indicates that the platform has been designed to integrate with other government digital initiatives, such as citizen identification systems and cultural databases. This interoperability enables the creation of a broader digital ecosystem where audiovisual services can be accessed in an integrated manner with other cultural and educational public policies. For instance, integration with school databases and administrators can provide restricted access to educational institutions for audiovisual content. In this way, the platform's reach is expanded, promoting digital inclusion and encouraging the population's access to Brazilian audiovisual content.

Thus, the interoperability of the Public Platform for Brazilian Audiovisual Content reinforces the commitment to a digital government that is efficient, secure, and accessible. It ensures that citizens can benefit from integrated, personalized services that meet their cultural and educational needs.

5. Final Considerations

The study demonstrates that the Public Platform for Brazilian Audiovisual Content, run by the Ministry of Culture, is an initiative aligned with the principles of the Digital Platform Government, centralizing access to national audiovisual content and promoting inclusion and cultural democratization. The analysis highlights how the platform strengthens citizen participation, data governance, and interoperability with other public policies and government initiatives focused on the creative economy. However, significant challenges remain, such as ensuring universal accessibility, data security and privacy, and financial sustainability, which are essential for its consolidation and effectiveness.

The technological and cultural challenges in implementing the platform encompass multiple dimensions. From a technological perspective, issues such as interoperability between government systems, integration with cultural databases, scalability, accessibility, connectivity, and the ability to process large volumes of data are fundamental aspects to ensure an efficient and secure service. The use of open standards, free software, and secure protocols can enhance the user experience and provide a safe and accessible digital environment for all.

From a cultural perspective, the platform must reflect the diversity of the Brazilian audiovisual landscape, encompassing productions from different regions, genres, contexts, and social groups. This requires policies that encourage national production, content curation that represents diverse identities, and accessibility strategies to ensure that people with disabilities can fully enjoy the provided content. Furthermore, digital exclusion remains a challenge, limiting the access of vulnerable populations due to infrastructural, cognitive, and socioeconomic barriers. Investments in digital literacy and expanding connectivity are crucial to mitigating this problem.

Digital exclusion in Brazil manifests in different ways, including instrumental exclusion, resulting from the lack of technological devices; infrastructural exclusion, due to limited connectivity in remote areas caused by the lack of cabling, signal, or internet transmission; cognitive exclusion, related to difficulties in understanding and using digital technologies; and institutional exclusion, when the lack of access prevents citizens from knowing or exercising their rights.

Finally, the platform's governance requires a transparent and participatory model that balances state regulation with collaboration from civil society and the productive sector, ensuring a democratic space for the dissemination and appreciation of Brazilian audiovisual content. It is crucial to foster a culture of innovation, overcome challenges related to digital exclusion, and implement secure practices for managing citizens' data. These aspects are essential to guarantee accessibility, transparency, and security in the use of digital technologies, promoting a more inclusive and efficient digital governance. Future research could further examine the social and cultural impacts of the platform, evaluating its effectiveness in promoting digital inclusion and fostering cultural democratization.

Based on these results, it is recommended that the Brazilian government implement public policies to ensure accessibility and interoperability between various digital platforms, including those beyond cultural ones. This will enable services such as education, healthcare, and social assistance to be accessed in an integrated manner. Furthermore, it is essential to promote public policies that encourage the production of independent audiovisual content, expand fiscal incentives, and provide subsidies for producers and artists from various regions, while

establishing a sustainable financing model for digital cultural platforms. This can be achieved through the creation of public-private partnerships.

This study acknowledges its limitations, as it is based on an initial exploratory study that relies on documentary data. Additionally, the dependence on information from the platform's current development stage may not accurately reflect its final version, so complementary studies may be needed as its implementation progresses. Therefore, this research contributes to the debate on the digitalization of public cultural services, emphasizing the importance of participatory governance models and the strategic use of digital technologies to expand access and diversity in the production and distribution of audiovisual content.

Track 9: Digital Transformation in Subnational Governments

Track Description

Digital transformation is an essential component of government strategies at both national and subnational levels, with an emphasis on secure citizen identification systems, data privacy, and digital inclusion. This track focused on the challenges subnational governments (states, regions, provinces, municipalities) face in implementing digital transformation. It seeks to highlight real-world cases, discuss the difficulties of integrating digital initiatives across different levels of government, and provide actionable recommendations for researchers, developers, and digital government practitioners. The track also aimed to (i) address collaborative governance, citizen participation, and federative or national-subnational relations in digital transformation; and (ii) foster discussions on overcoming the digital divide, enhancing cooperation between national and subnational levels, and developing more effective digital governance systems.
