Abstract. The digital transformation of public sector organizations is often hindered by bureaucratic rigidity, inefficient processes, and resistance to change. This study explores how Design Thinking can drive innovation in the Department of People Management at the Court of Auditors, addressing these challenges through a user-centered approach. Using a mixed-methods methodology, the research combines qualitative interviews with people management leaders and quantitative surveys with employees to identify inefficiencies and co-develop solutions. Key pain points include complex leave request workflows, lack of integration with digital tools, and communication gaps. To tackle these issues, Design Thinking was applied iteratively, facilitating collaborative workshops, prototyping, and continuous stakeholder engagement to develop a more efficient, automated leave management system. This solution improved transparency, accessibility, and decision-making, reducing administrative burden and enhancing regulatory clarity. The findings indicate that Design Thinking fosters problem-solving, streamlines people management processes, and promotes adaptability within bureaucratic institutions. By embedding empathy, co-creation, and iterative problem-solving into digital transformation efforts, this approach enables sustainable innovation in public sector organizations. The study contributes to the broader field of digital government by presenting a replicable framework for modernizing people management practices. Future research could assess the long-term impact of these interventions and explore their applicability to other domains of public administration, ensuring continuous improvements in efficiency, service delivery, and user experience.

Research paper, DOI: https://doi.org/10.59490/dgo.2025.963

1. Introduction

A public sector consists of government entities and state-controlled institutions responsible for governmental functions, regulation, and provision of public services Lane, 1993. Identifying the needs of this sector is crucial to formulating and improving effective public policies, allowing for the appropriate allocation of resources and efforts to efficiently and targetedly meet society's demands Nigro, 1984. However, the bureaucracy inherent to these sectors can make internal processes slow, compromising their effectiveness Cardoso Jr, 2011. To overcome this challenge, the introduction of technology has proven to be relevant, providing greater agility to processes de Oliveira et al., 2012; Haug et al., 2024.

When we understand that the concept of "public sector innovation" goes beyond the Schumpeterian vision, centered on a manufacturing logic Schumpeter, 1982, and begins to incorporate a perspective focused on services Jæger, 2013, we realize that the value to be delivered must be co-created with users Trischler and Scott, 2016. The capacity for co-creation becomes an indispensable factor for the development of innovations in public services that truly meet the demands of citizens Voorberg et al., 2015. Voorberg, Bekkers and Tummers Voorberg et al., 2015 highlight that co-creation involves everything from the engagement of citizens in the formulation of the service (as co-initiators) to their participation in the design and delivery of content (as co-developers).

The growing need to consider users as co-creators of value in public services poses a series of challenges to public management, which needs to transform itself into a more open and collaborative system. As a result, new methodologies become essential to allow users to co-create the experience they want to have Hanelt et al., 2021; Trischler and Scott, 2016.

To address these issues more effectively, the application of design thinking emerges as an innovative approach. By incorporating empathy, collaboration and creativity into the process of identifying requirements, design thinking provides a more holistic and user-centered way to solve these challenges Melo and Abelheira, 2015. At the heart of this approach is the concept of design thinking, a mindset that transcends the mere literal interpretation of a designer, implying the use of methods adapted to individual needs and making use of available technologies to create value for the user Silva et al., 2012. Furthermore, the application of design thinking results in effective problem-solving, differentiating itself from other approaches that often limit themselves to formulating the problem without achieving a concrete solution Martin, 2009.

In this context, the Court of Auditors of the State of Pernambuco (TCE-PE), the institution responsible for monitoring and auditing public resources in the state, has chosen to make significant investments in technological innovation. The goal is to speed up and improve its internal processes, aiming at a more efficient and transparent management of public resources. However, the court's employees often face challenges in explaining and articulating complex everyday issues, which can result in inadequate and ineffective solutions. The study focuses on using the Design Thinking approach to guide innovation in the Human Resources Department of the Court of Auditors of Pernambuco, aiming to reduce the rigidity intrinsic to institutional bureaucracy. Through this approach, we seek to develop an efficient, intuitive solution adapted to the needs of employees and, as a consequence, disseminate the technique and promote improved deliveries to society, in addition to improving people management processes, automating tasks, integrating information, facilitating data analysis and promoting greater agility and effectiveness in related activities.

2. Related Works

The rapid changes taking place in the contemporary world and the recognition of the limitations of the dominant model of public policy implementation (policymaking) point to the need to discuss the possibilities that open up for public administration, based on the incorporation of design thinking principles and their contributions both to a better understanding of public problems and to the construction of more effective government solutions. However, we still lack structured knowledge about this co-creation approach, especially how it fits into current policymaking practices and public organizations Cavalcante et al., 2019.

Based on this, governments around the world have sought support from this framework to implement co-creation processes (Ansell and Torfing, 2014). In Brazil, Santos and Hoffmann Santos and Hoffmann, 2016 conducted research with the aim of proposing a methodology for the design and implementation of more effective public services, applied in the context of a project in the city of Florianópolis, based on the concepts of Service Design and Project Management. In addition, Cavalcante Cavalcante et al., 2019 organized a collection that enriched the debate on the culture of innovation in Brazil, by presenting and discussing cases that implement innovative methods and approaches to management and public policies in different sectors and levels of government.

On the other hand, Voorberg et al. Voorberg et al., 2015 highlight the lack of empirical knowledge on co-creation, in addition to the scarcity of evidence that positions it as a significant strategy. These authors also raise important questions, such as the objectives of co-creation with citizens, the factors that influence the process and the expected results.

Trischler and Scott Trischler and Scott, 2016 add to these questions the lack of studies on user engagement methods in service design in different contexts of the public sector. Similarly, Cavalcante Cavalcante et al., 2019 highlights that, despite the progress in Brazil in the development of materials and in the training of civil servants to disseminate design thinking in government, it is necessary to understand its principles in greater depth in order to promote and incorporate this approach effectively. For Cavalcante Cavalcante et al., 2019, there is still a lack of structured knowledge on how this approach fits into the current practices of public organizations.

3. Methodology

Improving people management processes is a fundamental objective for organizations seeking efficiency, productivity and innovation. In the context of the Court of Auditors of Pernambuco, this improvement becomes even more crucial, given the strategic role played by this body. To achieve this objective, this study adopts a rigorous and comprehensive approach, centered on the application of a mixed research methodology. The core of this approach lies in the combination of quantitative and qualitative methods, allowing for a complete and multifaceted understanding of the challenges and opportunities faced in the area of people management. This article outlines the steps and procedures adopted to conduct this research, highlighting the importance of each phase and the synergy between them to achieve the proposed objectives.

Through in-depth interviews and questionnaires, we sought not only to identify gaps and areas for improvement in existing processes, but also to understand the perceptions and experiences of the managers and professionals involved. This in-depth understanding serves as a basis for proposing effective and sustainable solutions, aligned with the specific needs and realities of the Court of Auditors of Pernambuco.

By adopting an exploratory-sequential approach, starting with a qualitative investigation and expanding to a quantitative analysis, we hope to obtain valuable and informed insights into the challenges and opportunities in people management in this context.

3.1. Objective of the Study

By exploring the steps, this article aims to understand the application of design thinking in the redesign of public products and services, and as a consequence, disseminate the technique and promote the improvement of deliveries to society.

The ultimate goal of this study is to show how innovative co-creation solutions can be adopted in public environments to automate tasks, integrate information, facilitate data analysis and promote greater agility and effectiveness in the services provided to society.

3.2. Study Type

This is a mixed-methods study, combining quantitative and qualitative methods to obtain a comprehensive understanding of people management processes. The study adopted an exploratory-sequential design, where the qualitative phase precedes the quantitative phase. First, interviews were conducted to explore in depth the perceptions of people managers, since the researchers were unaware of the current problems in the court of auditors. The main objective was to identify what the main problems were and their order of priority given the needs of the managers. The interviews with the managers took place every two weeks and a questionnaire was carried out with the employees in order to obtain a diversity of perspectives in the sector.

3.3. Sample

The sample was composed of two distinct groups:

- **Interviews:** 7 people managers were intentionally selected to participate in the interviews. The selection was based on their experience and knowledge about the people management processes in their respective organizations. It was also considered that it would carry out the management process of authorizing vacation requests.
- **Questionnaires:** 48 professionals in the area of human resources management responded to the questionnaire. In order to map the main problems that vacation requesters had.

3.4. Data Collection

The data was collected in two distinct phases:

- **Qualitative Phase:** Semi-structured interviews were conducted with the 7 human resources managers between March and October 2023. Each interview lasted an average of one hour and was recorded and transcribed for later analysis.
- **Quantitative Phase:** A structured questionnaire was distributed to 48 human resources management professionals during June 2023. The questionnaire included closed-ended questions and Likert scales to measure perceptions about the effectiveness of human resources management processes and the use of automated technologies.

3.5. Research Instruments

- **Recording and Transcription of Interviews:** The interviews were recorded via Google Meet with the consent of the participants and later transcribed for analysis.
- **Analysis and Synthesis of the Questionnaires:** The questionnaires were analyzed quantitatively to create empathy and persona maps.

3.6. Procedures

- **Interview Preparation:** The interviews were conducted in person or via videoconference, depending on the availability of the participants.
- **Questionnaire Development:** The questionnaire questions were developed based on the results of the interviews with the managers, since they also requested vacations from the court.
- **Qualitative Data Analysis:** The interview transcripts were analyzed to map problems in the processes, identify solutions, and define new rules for requesting vacations.
- **Quantitative Data Analysis:** The questionnaire data were analyzed and inferential analyses were performed to identify significant correlations and differences in the participants' perceptions.

4. Application of Design Thinking to Promote Digital Transformation

To achieve the objectives proposed in this study, an approach based on design thinking will be adopted, a human-centered methodology that promotes innovation through multidisciplinary collaboration, empathy and iterative experimentation Brown, 2009. Design thinking is composed of a series of interconnected steps, which will be followed in this project to guide innovation in the Human Resources Department of the Court of Auditors of Pernambuco. Figure 2 illustrates the application of Design Thinking to promote digital transformation.

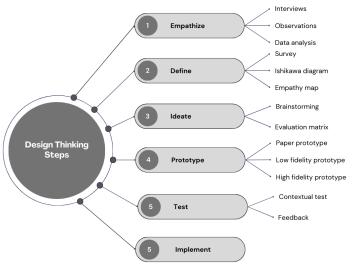

Fig. 1 – Stages in the Development of Design Thinking.

4.1. Empathic Understanding.

4.1.1. Preparatory phase:

Relevant information about the organization was gathered to understand the activities provided, the organizational structure, the organization of workflows, and the management maturity of the agency. The research

team conducted an initial survey with the main stakeholders in order to understand the organizational problems and the context of the work of the employees, as well as the suggested units. From this meeting, it was possible to identify a scope of the main problems faced by the DGP management, as well as to prioritize them.

4.1.2. Kick off:

After defining the scope, together with the confirmation of the research schedule, the data collection activities were formally initiated through meetings that would occur biweekly a priori, and could be scheduled weekly when necessary. This meeting will be attended by the project coordinators from UFRPE, the agency to be dimensioned TCE-PE and the units involved and will be held from March to August 2024. During these meetings, in addition to presenting the objectives and the expected schedule for data collection, the teams from the agency and UFRPE will ask the managers of the selected organizational units to appoint a supporter to their teams. This supporter will streamline contacts during the data collection process and will serve as a collaborator formally appointed by the manager to assist in subsequent tasks.

In order to ensure the efficiency of the meetings, the team from the organizational unit that will be present at the interviews may be composed only of the manager and the designated supporter. Alternatively, other people from the unit may participate, as long as they are appointed by the manager and there is an explicit justification for the need for their support. The presence of these individuals will be conditioned on the justification presented by the manager.

During the closing of the inaugural meeting, the manager of the organizational unit will be asked to fill out a document, with or without the support of members of his/her team, within the deadline agreed upon during the meeting, not exceeding seven days. This document aims to collect preliminary information about the processes and deliverables carried out by the organizational unit. This information will be analyzed by the researchers to optimize the next meetings and guide the next steps of the research process.

This stage consisted of 4 meetings and the table 1 illustrates the main issues faced in the process were identified.

Issue	Description
Process Complexity	The existence of many steps and signatures in the leave request and authorization process can make the workflow bureaucratic and time-consuming, leading to dissatisfaction and delays for employees.
Lack of Integration with Work Calendar	The absence of a functionality that allows the leave system to integrate with the employees' work calendar can result in incorrect calculations of the leave period to be paid, causing rework and manual adjustments.
Difficulties in Leave Accounting	The system's difficulty in correctly accounting for employees' return dates from leave can lead to incorrect payments and inconsistencies in records, causing financial and administrative impacts.
Accumulation of Employee Leave	The occurrence of leave accumulation by employees, even though it is prohibited, can generate future issues related to labor liabilities and negatively impact the organization's leave management.
Inadequate Communication	The lack of clear and transparent communication about the rules and procedures of the Leave Schedule System can create doubts and misunderstandings among employees, making it difficult to comply with established policies.

Tab. 1 – Issues in the Leave Management System

4.2. Problem Definition.

From the empathy phase, we moved on to problem definition, where the main objective of this stage was to clearly and objectively establish the scope of the problem to be solved, ensuring alignment among all those

involved in the process. An in-depth understanding of the problem is essential for us to be able to develop effective solutions that are in line with the reality of the users.

To structure the analysis of the problem, we used the Ishikawa Diagram, also known as the cause and effect or fishbone diagram. This tool allowed us to map the possible causes of the problem in a visual and organized way, identifying factors such as processes, people, tools, methods and environment that directly impacted the situation under study. This artifact made it possible to prioritize the most relevant causes and helped in formulating initial hypotheses for the next stage.

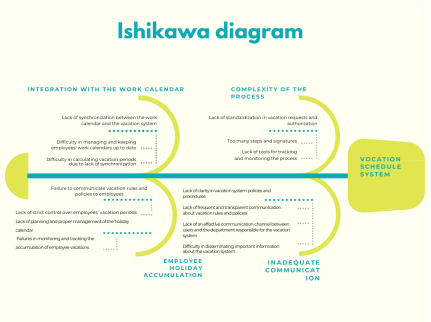

Fig. 2 – Ishikawa Diagram

In addition, we turned our attention to a more in-depth understanding of the users impacted by the process under study. The focus was to consolidate the information collected and validate whether the initial perception of the problem corresponded to the reality of all those involved.

We began this process with users from the DGP (Human Resources Management Department), where we created an Empathy Map and a Persona to represent this group. These two artifacts were essential to understanding their pain points, needs, expectations and behaviors in relation to the problem.

To validate this understanding, we created a form with pertinent questions, seeking to understand whether the DGP's perceptions were shared by others involved in the vacation request and management process. The form was widely distributed among employees and managers, and its analysis generated two new Empathy Maps and two new Personas, expanding our view of the problem and ensuring that the proposed solutions were based on different perspectives.

User Type	Stakeholders Summary
HR Personnel (DGP)	Maya hears that due to the low effectiveness of the current system, vacation days are accumulating. She feels frustrated with the rigid process and wants improvements. She constantly reviews requests and deals with heavy rework. She sees that technology in other areas is effective. Maya, 27, works in HR. She manages vacation requests and needs to integrate them with payroll. She ensures compliance with regulations and avoids excessive vacation accumulation. She is tech-savvy and aims to make the tool more user-friendly.
Employee	Lisa desires system integration and a mobile app for vacation tracking. She values flexibility and clear rules but struggles with the current complex system. She seeks an intuitive interface and shared calendars. Lisa, 27. She wants a simpler vacation request process, mobile access, and notifications. She struggles with process complexity and unclear information but sees opportunities in system improvements.
Manager	Carla hears employee concerns about work-life balance. She wants better internal communication about vacation policies. She feels pressure to manage requests fairly and is frustrated by the lack of clear visibility on vacation balances. Carla, 42, is a team manager. She needs detailed reports on vacation balances, efficient request coordination, and compliance with labor laws. She values technology solutions to automate notifications and decision-making.

Tab. 2 – Stakeholders Summary

These artifacts were essential to deepen our understanding of the problem and ensure that the proposed digital transformation was truly user-centric, meeting their needs and resolving the identified pain points.

4.3. Ideation.

In this step, a collaborative brainstorming session was conducted to generate a wide variety of creative ideas to solve the identified problem. All ideas were welcome and will be explored without initial criticism, encouraging innovation and creativity. This phase focused on generating ideas and solutions to the identified problems. Initially, we conducted a group brainstorming session, where we discussed various measures that could be implemented to solve the challenges faced. During this session, we explored different approaches and considered different perspectives to ensure a wide variety of ideas.

To evaluate the generated ideas, we constructed a solution matrix(see tab. 3). In this matrix, the Y-axis represented the expectations gathered from customers and stakeholders, while the X-axis represented the overall proposals developed by the team. Each idea was evaluated and scored according to its feasibility and alignment with the expectations of those involved. Based on the selected ideas, we moved forward to creating a prototype. The prototype served as a tangible representation of the proposed solution, allowing for a better visualization and understanding of how the solution would work in practice. This artifact was fundamental in directing the subsequent development of the solution, ensuring that it met the needs and expectations of end users.

	Current system	BPMN	Application
Feasibility	x	o	o
Usability	x	x	o
Maintainability	x	o	o
Monitoring	x	x	o

Tab. 3 – Evaluation Matrix

4.4. Testing and Evaluation.

In the testing and validation phase, the developed prototype underwent a series of rigorous evaluations to ensure its effectiveness and usability. These tests were conducted with users representative of the target audience, allowing the identification of possible flaws and areas that needed improvement. In addition, the prototypes were evaluated in a simulated or pilot environment with the collaboration of the Human Resources Department. User feedback was carefully collected and analyzed to measure the effectiveness and usability of the proposed solutions. Based on the results obtained, the prototypes were adjusted and refined as necessary until the final version of the product was reached.

4.5. Implementation and Iteration.

After the successful validation of the prototype, the project was forwarded to the software factory for the development of the final solution. This stage marked the transition from the design and prototyping stage to the practical implementation of the solution, where developers would work to transform the prototype into a functional and robust application. The involvement of the software factory at this stage would ensure that the prototype specifications and requirements are properly translated into code, culminating in the delivery of a final solution aligned with the expectations and needs of the end users and stakeholders involved in the project. Finally, the validated solutions will be implemented in the HR department's work environment. During this phase, special attention will be given to employee training and the integration of new practices into the existing workflow. In addition, a continuous monitoring and evaluation plan has been established to identify opportunities for improvement and iterate on solutions as needed.

5. Discussion

The results of this study demonstrate the effectiveness of applying the design thinking methodology to innovate people management processes at the Court of Auditors of Pernambuco. The approach allowed for a deep understanding of the needs and challenges faced by the department, promoting user-centered solutions that aim to increase the efficiency and effectiveness of the activities carried out.

5.1. Empathetic Understanding

The empathetic understanding phase was crucial to identify the particularities of the Court of Auditors of Pernambuco. The initial research and interviews allowed for a detailed diagnosis of the organization, facilitating the classification of the agency and the definition of the units and services to be dimensioned. This initial diagnosis guided all subsequent steps, ensuring that the solutions developed were appropriate to the specific context of the organization.

5.2. Problem Definition

The problem definition stage was essential to synthesize the information collected and identify the main challenges to be addressed. The collective interviews and the analysis of the documents submitted by the managers of the organizational units provided a clear overview of the internal activities and processes. This detailed understanding allowed the formulation of well-defined problems, which served as a basis for the ideation of innovative solutions.

5.3. Ideation

The collaborative brainstorming session generated a wide variety of creative ideas to solve the identified problems. The use of a solution matrix allowed the evaluation and prioritization of the ideas based on feasibility and alignment with the expectations of the stakeholders. This process ensured that the selected solutions were not only innovative, but also practical and aligned with the needs of the end users.

5.4. Prototyping

The low and high fidelity prototypes developed during the prototyping phase were essential to test and refine the generated ideas. The use of mood boards and the incorporation of elements from existing tools, such as Google Calendar, ensured that the prototypes were intuitive and familiar to the users. This iterative approach allowed the prototypes to evolve based on employee feedback, resulting in solutions that were well-tuned to the real needs of the organization.

5.5. Testing and Evaluation

The testing and evaluation phase validated the effectiveness and usability of the developed prototypes. Testing conducted with representative users and in simulated environments allowed identifying areas for improvement and adjusting the prototypes as needed. This rigorous validation process ensured that the final solution was robust and aligned with the expectations of users and stakeholders.

5.6. Implementation and Iteration

The implementation of the validated solutions in the HR Department's work environment marked the transition to practice. Employee training and integration of the new practices into the existing workflow were essential to ensure successful adoption of the developed solutions. The established continuous monitoring and evaluation plan will allow identifying opportunities for improvement and iterating on the solutions as needed, ensuring the sustainability and effectiveness of the implemented innovations.

5.7. Practical Implications

The results of this study have significant practical implications for HR management in the public sector. The human-centered approach and iterative design thinking methodology have proven to be effective in solving complex problems and fostering significant innovations. The application of this methodology can be extended to other areas and organizations, contributing to the continuous improvement of public processes and services.

5.8. Lessons Learned

Throughout the collaboration between TCE-PE and UFRPE to improve people management processes, several crucial lessons were learned:

1. **Stakeholder Engagement:** Actively involving leaders and employees from the beginning was essential to align initiatives with strategic objectives. Engaging stakeholders not only ensured their support, but also fostered a sense of ownership and commitment to the success of the project. Their contributions provided valuable insights into the organization's priorities and helped shape solutions to meet specific needs.

2. **Comprehensive Data Collection:** Employing diverse data collection methods, focus groups, surveys, and online forms, enabled a holistic understanding of employee needs. By bringing together data from multiple sources and perspectives, including quantitative and qualitative data, a comprehensive view of the challenges and opportunities within the organization was obtained.
3. **Rigorous Data Analysis:** Applying rigorous qualitative analysis techniques, such as Thematic Synthesis, facilitated the accurate identification of key patterns and issues. By closely examining the collected data, themes and trends emerged, enabling a deeper understanding of the causes of problems and guiding the development of targeted solutions.
4. **Interdisciplinary Collaboration:** Working with a multidisciplinary team enriched problem-solving with diverse perspectives. Bringing together experts from different disciplines, including HR, IT, psychology, and business management, encourages innovative thinking and creative approaches to problem-solving. This interdisciplinary approach ensured that solutions were robust and addressed the multifaceted nature of organizational challenges.
5. **Stakeholder Validation and Feedback:** Incorporating stakeholder feedback increased the relevance and acceptance of proposed solutions. By soliciting input from those directly impacted by the changes, solutions were tailored to meet their specific needs and preferences. Stakeholder validation also fostered a sense of inclusion and transparency throughout the project.
6. **Prioritization:** Setting clear priorities based on the severity of issues allowed for effective resource allocation. By identifying and prioritizing the most pressing issues, resources could be directed to areas with the greatest potential for impact. This strategic approach ensured that efforts were focused on addressing the organization's most critical needs.
7. **User-Centered Solutions:** Prioritizing user experience promoted greater engagement and adoption of implemented solutions. By designing solutions with end-users in mind, usability and accessibility were prioritized, leading to higher levels of acceptance and satisfaction among employees. User-centered design also encourages ongoing feedback and iteration to constantly improve the user experience.
8. **Commitment to Continuous Improvement:** Maintaining a mindset of continuous improvement ensured that solutions remained relevant to evolving needs. Recognizing that organizational needs and priorities change over time, a commitment to continuous evaluation and refinement was essential. This iterative approach allowed solutions to be adapted and optimized to meet emerging circumstances and challenges.

These lessons underscore the importance of a collaborative, data-driven, and user-centered approach to improving people management processes at TCE-PE.

6. Conclusion

This study explored the application of the design thinking methodology to improve people management processes at the Court of Auditors of Pernambuco. Through a human-centered approach that involved empathy, multidisciplinary collaboration, and iterative experimentation, it was possible to develop innovative and effective solutions to the challenges faced by the Human Resources Department.

The empathetic understanding phase allowed a detailed diagnosis of the organization, identifying specific needs and challenges. The clear definition of the problems, based on interviews and document analysis, provided a solid basis for the generation of innovative ideas during the ideation phase. Iterative prototyping, with continuous feedback from users, ensured that the solutions developed were well-adjusted to the real needs of the organization.

Rigorous testing and evaluation of the prototypes validated the effectiveness and usability of the solutions, while practical implementation and employee training ensured successful adoption of the new practices. The established continuous monitoring plan will allow constant adjustments and improvements, ensuring the sustainability of the innovations.

The results of this study indicate that the design thinking methodology is an effective approach to solving complex problems in people management in the public sector. The adoption of this methodology can promote greater agility, efficiency and employee satisfaction, contributing to the continuous improvement of organizational processes.

However, it is important to recognize the limitations of this study, such as the relatively small sample size and the need for long-term follow-up to assess the full impact of the solutions implemented. Future studies can expand the application of design thinking to other areas and sectors, as well as explore different organizational contexts, to validate and expand the findings of this work.

In short, this study demonstrated that human-centered innovation, promoted by design thinking, can significantly transform people management, providing practical solutions that are adaptable to the specific needs of each organization.

Abstract. The integration of Open Innovation (OI) and Digital Transformation (DT) is relevant in the public sector, particularly in developing countries where resource constraints demand innovative approaches. OI fosters collaboration between governments, businesses, academia, and civil society, enabling the co-creation of digital solutions that enhance public service efficiency and transparency. In this context, intermediaries play a fundamental role in bridging technical capabilities and institutional needs, facilitating policy implementation, and overcoming cultural and financial barriers. However, while OI and DT have been studied independently, little research has examined how intermediary-driven OI influences the digital transition in government settings. This study investigates the role of federal public institutions as intermediaries in Brazil's OI-driven DT efforts, analyzing how they facilitate innovation adoption at the state and municipal levels. Through a case study of two federal-level institutions, the research identifies key mechanisms by which intermediaries promote digital integration and examines the challenges they face, including budget limitations and resistance to change. The findings identify the strategic role of these institutions in mitigating administrative and legal barriers and in fostering cross-sector collaboration.

Research paper, DOI: https://doi.org/10.59490/dgo.2025.964

1. Introduction

The pursuit of efficiency and innovation is driving the public sector globally towards strategic approaches integrating technology and collaboration. In many developing countries, DT has become essential for modernizing processes, improving service delivery, and meeting contemporary societal expectations (de Lima-Junior et al., 2024; Escobar et al., 2023). DT involves enhancing organizational performance by incorporating information, computing, communication, and connectivity technologies (Vial, 2019), a process that was once confined to the private sector.

Complementarily, OI has emerged as a valuable strategy promoting external collaboration and idea exchange to foster development and innovation (Brockman et al., 2018). Initially a the private sector concept (Biscotti et al., 2018; Bogers et al., 2016), OI is now gaining traction in the public sector due to its potential for citizen engagement in public affairs and participatory governance, enhancing collective intelligence and co-creation to address complex societal challenges (Androutsopoulou et al., 2017; Criado and Guevara-Gómez, 2021; Ferraris et al., 2020; Gascó, 2017; Mergel et al., 2019).

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Although OI initiatives—especially those focusing on open government and open data—have fostered greater transparency and citizen participation in public management (Gasco-Hernandez et al., 2017; Mergel et al., 2019), most research to date has centered on citizen inclusion, with limited involvement from businesses, academia, and other public organizations (Figenschou et al., 2024).

OI has an interplay with DT where OI promotes the development of new technologies that support DT (Robertsone and Lapiņa, 2023). More recently, the integration of OI into DT efforts has gained prominence, particularly in developing countries where resource constraints and unique needs drive innovative approaches (Debeljak and Dečman, 2022; Gong et al., 2020; Mu and Wang, 2022). In this context, intermediaries play a key role by facilitating knowledge sharing and policy implementation in increasingly digital and networked environments (Mu and Wang, 2022; Palumbo et al., 2023). These intermediaries—ranging from specialized consulting firms and technology companies to nonprofit organizations—bridge the gap between technical capabilities and institutional needs, mitigating cultural, financial, and technological barriers. Recent studies have emphasized their role in supporting collaboration, reducing uncertainty, and enabling value co-creation among diverse stakeholders in innovation ecosystems (Figenschou et al., 2024; Pinto et al., 2024).

Despite these advancements, significant research gaps remain. Although DT is widely recognized as key to improving public service delivery and operational efficiency, there is a notable lack of empirical studies that explore the strategies employed –especially those involving intermediary agents in OI projects – to drive DT effectively (de Lima-Junior et al., 2024; Gong et al., 2020). Furthermore, while numerous studies have examined the success of OI in various contexts, little attention has been paid to the intersection of OI and DT in the public sector, particularly regarding how intermediary-driven OI can either facilitate or hinder the digital transition (Criado and Guevara-Gómez, 2021).

In Brazil, federal public institutions have emerged as central intermediaries in the OI process. These institutions connect diverse actors, promote the integration of digital technologies, and help overcome structural and procurement barriers (Pinto et al., 2024). This intermediation not only enhances the capacity of public agencies to adapt to technological changes but also fosters a collaborative culture among government, academia, the private sector, and civil society.

This article aims to deepen our understanding of the role of intermediaries in OI for DT within the public sector. Through a case study of two federal-level institutions acting as OI intermediaries with Brazilian states and municipalities, this research seeks to answer the following central question: *How do Brazilian federal institutions, acting as OI intermediaries, drive DT in the public sector, and what factors influence the outcomes of this process?*

This case study highlights federal intermediaries as key facilitators of technological solutions and stakeholder collaboration. Despite their role in overcoming administrative barriers, budget constraints and resistance to change remain major challenges to fully realizing DT through OI.

2. Background and Related Work

2.1. Digital Transformation in Government

DT has become fundamental for modernizing the public sector, aiming for greater efficiency and improved service delivery to citizens (Gong et al., 2020; Vial, 2019). In the governmental context, DT involves the incorporation of digital technologies to optimize administration and increase transparency (Verhoef et al., 2021). DT entails structural changes that improve operations and redefine government–society relations (Hanelt et al., 2021; Vial, 2019). This becomes particularly relevant amid growing demands for more accessible, inclusive, and personalized public services (Kraus et al., 2021).

In contrast to the private sector, public organizations face specific challenges in digitalizing their services, such as bureaucratic rigidity, limited financial resources, and cultural resistance to change (Hanelt et al., 2021; Tiach and Abdellatif, 2023). Advances in artificial intelligence, big data, and blockchain offer significant opportunities to overcome DT challenges in the public sector, enabling the automation of processes, the protection of data, and making digital services more effective (Escobar et al., 2023; Verhoef et al., 2021).

DT in public administration extends beyond internal improvements, serving as a catalyst for transparency, civic engagement, and collaborative governance (Figenschou et al., 2024). By enabling citizen participation through digital platforms, DT fosters public trust and democratic legitimacy (Edelmann et al., 2023; Palumbo et al., 2023). Central to this process is the creation of digital ecosystems that engage diverse stakeholders in co-developing solutions for key public challenges such as mobility, health, and education (Ferraris et al., 2020; Robertsone and Lapiņa, 2023).

DT requires long-term strategies that tackle institutional and cultural barriers (Gong et al., 2020; Mu and Wang, 2022). This includes investing in digital competencies for public servants, designing adaptive regulatory frameworks, and cultivating an innovation-oriented organizational culture (Edelmann et al., 2023; Tiach and Abdellatif, 2023). Recent empirical studies suggest that governments adopting strategic, participatory, and multi-stakeholder approaches to DT are more likely to improve not only operational efficiency but also public legitimacy and citizen satisfaction (Figenschou et al., 2024; Tiach and Abdellatif, 2023).

2.2. Open Innovation

OI has gained increasing importance in the public sector as a strategy to develop innovative solutions in collaboration with external actors. This model allows for combining internal resources with external knowledge to address complex challenges and improve service delivery (Bogers et al., 2018; Figenschou et al., 2024; Mu and Wang, 2022; Palumbo et al., 2023). In contemporary public and private contexts, OI enables the creation of dynamic networks that accelerate innovation and improve responsiveness to complex societal demands (Goulart et al., 2023; Pinto et al., 2024).

The knowledge exchange intrinsic to OI unfolds in both inbound and outbound flows. Inbound flows allow external contributions—such as ideas, data, and prototypes—to improve internal processes, while outbound flows disseminate innovations via partnerships, licensing, and public–private collaborations (Gasco-Hernandez et al., 2017; Mu and Wang, 2022). Particularly in the public sector, these flows are facilitated by intermediary actors and digital platforms, which expand the scope of participation and collaboration (Figenschou et al., 2024; Smith and Akram, 2017).

OI increasingly relies on active user participation, from identifying problems to co-developing solutions (Edelmann et al., 2023; Ferraris et al., 2020). This participatory logic—known as user-driven innovation, co-creation, or citizen-sourcing—enhances the legitimacy, diversity, and impact of innovation outcomes (L. and D., 2018; Palumbo et al., 2023). By embedding user engagement across multiple stages of innovation, organizations can align their outputs more closely with societal needs and expectations, especially in complex domains such as healthcare, mobility, and digital government services (Figenschou et al., 2024; Mu and Wang, 2022).

Collaborative innovation models are especially pertinent in the public sector, as they enhance both the effectiveness and legitimacy of policies and services (Criado and Guevara-Gómez, 2021; Figenschou et al., 2024). This reflects a broader transformation in digital governance, where trust, transparency, and inclusiveness are central to the creation of public value (Palumbo et al., 2023; Tiach and Abdellatif, 2023).

2.3. OI in the Public Sector

Public institutions are increasingly adopting OI to address complex challenges, inspired by its success in the private sector (Biscotti et al., 2018; Bogers et al., 2016; Gascó, 2017). OI initiatives in the public sector have expanded, driven by goals such as participatory governance, data-informed policymaking, and digital transformation (Figenschou et al., 2024; Mu and Wang, 2022; Palumbo et al., 2023). This approach enhances citizen engagement, leverages collective intelligence, and supports the development of innovative and context-sensitive solutions (Brabham, 2013; Ferraris et al., 2020). By integrating diverse actors into decision-making, OI fosters transparency, legitimacy, and efficiency, while helping to overcome bureaucratic barriers through more collaborative and responsive structures (Figenschou et al., 2024; Mu and Wang, 2022; Palumbo et al., 2023).

However, OI reveals marked differences between the private and public sectors, reflecting their distinct goals. While the private sector emphasizes product development and competitive advantage to drive economic performance (Kivleniece and Quélin, 2011), the public sector prioritizes service quality and the creation of public

value through inclusive and effective responses to social demands (Palumbo et al., 2023). Moreover, public sector OI typically involves broader stakeholder engagement—such as citizens, NGOs, and academia—highlighting its participatory and collaborative character.

2.4. Intermediaries

Public Open Innovation (POI) intermediaries are crucial strategic actors for driving collaborative innovation and DT in the public sector. They connect governments, businesses, universities, and citizens, facilitating the implementation of innovative solutions (Al Maazmi et al., 2024; Figenschou et al., 2024). In public sector contexts, their role is particularly crucial for overcoming institutional inertia and cultural resistance, enabling more inclusive, transparent, and participatory governance arrangements (Mu and Wang, 2022; Palumbo et al., 2023). By bridging gaps between stakeholders and orchestrating multi-actor efforts, intermediaries not only reduce transaction and coordination costs but also enhance the scale and impact of OI initiatives in governmental settings (Pinto et al., 2024; Smith and Akram, 2017).

One of the primary challenges faced by intermediaries in the public sector is navigating bureaucratic rigidity and inflexible organizational structures, which often hinder the implementation of collaborative innovation processes (Mu and Wang, 2022; Palumbo et al., 2023). Additionally, these organizations must operate under budgetary constraints and within highly regulated environments, conditions that can limit experimentation and adaptive governance (Figenschou et al., 2024). To overcome these barriers, intermediaries adopt strategies such as digital platforms, hackathons, and public-private partnerships, all of which support agile collaboration across sectors (Gasco-Hernandez et al., 2017; Smith and Akram, 2017).

POI intermediaries play a strategic role in fostering innovation-oriented cultures in government by developing digital and collaborative competencies among public servants (Mittal, 2020). They also enhance the resilience of public innovation ecosystems by promoting access to emerging technologies and strengthening engagement with civil society. Empirical evidence highlights a strong correlation between well-structured intermediaries and the success of digital transformation initiatives in the public sector (Al Maazmi et al., 2024; Mittal, 2020).

Recent studies have significantly expanded this understanding by incorporating dimensions such as data intermediation, digital capacity-building, and regulatory orchestration (Al Maazmi et al., 2024; Mu and Wang, 2022; Palumbo et al., 2023). These contemporary perspectives are essential to frame federal public institutions as dynamic actors within multilevel innovation ecosystems.

3. Method

3.1. Case Study

Case studies explore ongoing events by integrating evidence from various sources (Yin, 2014). Moreover, a single case may be analyzed using multiple units of analysis (Runeson, 2012). For this case study focusing on federal-level institutions acting as OI intermediaries, two units of analysis were selected. The objective is to explore how OI is driving DT in terms of activities, procedures, and interactions through intermediaries, analyzing the process from the perspective of key individuals responsible for operationalizing intermediation.

Given the exploratory nature of understanding the mechanisms by which federal institutions act as OI intermediaries to drive DT, and the need to analyze real-world practices within their specific contexts, a case study approach is particularly well-suited (Yin, 2014) using qualitative guidelines (Merriam and Tisdell, 2015).

3.2. Units of analysis

We selected the two units of analysis (Enap Challenges Platform and Serpro Ventures) through purposive sampling. Such approach allows researchers to intentionally select cases that offer rich, relevant insights into the phenomenon under study, making it ideal for qualitative research (Patton, 2014).

1. Enap Challenges Platform, led by National School of Public Administration (ENAP) through GNova, connects government and civil society to address public challenges via OI. The platform enables public

managers to launch challenges, inviting citizens, startups, and academics to propose solutions. It supports managers with toolkits, mentorships, and personalized assistance for challenge formulation and management.
2. Serpro Ventures, led by Federal Data Processing Service (SERPRO), drives DT and inclusion in federal agencies through OI. It fosters partnerships with academia, startups, research centers, and companies to develop intelligent solutions. As a federally owned company, Federal Data Processing Service (SERPRO) manages and implements IT policies for the Brazilian government.

The chosen institutions have emerged as key federal intermediaries of OI in Brazil. Enap Challenges Platform represents a model focused on broad engagement with diverse external stakeholders through open challenges, while Serpro Ventures embodies a more structured approach leveraging partnerships with specific innovation actors within the federal IT landscape. Through the Desafios Platform, ENAP has facilitated over 60 public challenges across various levels of government, fostering co-creation with startups, universities, and other actors within the innovation ecosystem. In parallel, SERPRO, through the Serpro Ventures program, has implemented approximately 200 initiatives aimed at driving DT in the public sector, combining hackathons, partnerships with ICTs, and formal co-creation models with private market actors.

The selection was informed by three main criteria: (i) the existence of structured OI mechanisms, (ii) recognition in regional or national DT agendas, and (iii) feasibility of access to relevant data and key informants. These criteria ensured the suitability of the cases for investigating the role of public intermediaries in driving DT. Their distinct yet complementary approaches enable a comparative analysis of different models and their impact on government innovation.

3.3. Data collection and analysis

For this study, documents and interviews were carefully selected to ensure data triangulation and validity (Eisenhardt, 1989; Yin, 2014). Official documents (ordinances, laws, public notices) provided information about legal frameworks, while initiative websites clarified guidelines and key actors.

Semi-structured interviews with leaders and technical staff ensured core perspectives, given the small project teams. In parallel, a systematic literature review (de Lima Júnior et al., 2024) identified four analytical dimensions—innovation approaches, stakeholders, influencing factors, and the role of technology—which informed the interview protocol and guided the processes of triangulation and thematic coding, thereby strengthening the qualitative analysis.

The interview protocol aimed to explore institutional OI practices, involved stakeholders, enabling and hindering factors, and the role of technology in DT efforts. Interviews were conducted remotely via Google Meet, with prior informed consent and subsequent transcription assisted by AI and manually refined. Participants were briefed on analytical dimensions to clarify the study's scope. A thematic analysis was performed following Braun and Clarke's approach (Braun and Clarke, 2006), combining deductive coding from predefined constructs with inductive identification of emerging themes. Initially based on four analytical dimensions, the framework evolved into five core themes: practices, stakeholders, enablers, barriers, and technologies.

3.4. Participant selection

Participants were selected based on a thorough analysis of the profiles of the key organizers of each initiative, according to information available on institutional websites. After the initial contact with the organizations and the presentation of the research objectives, the interviewees promptly expressed their interest in contributing. Consequently, two key individuals per initiative were selected, following the criterion that they should hold strategic positions in the planning, coordination, and execution of the full OI cycle. A detailed description of the interviewees' profiles can be found in Table 1.

4. Results

4.1. Enap Challenges Platform

Enap Challenges Platform connects public agencies with startups, universities, and citizens to solve public challenges via the Desafios platform. ENAP, a Federal Public School, acts as an innovation intermediary, of-

Tab. 1 – Profile of interviewed participants.

Part.	Initiative	Position
I1	Enap Challenges Platform	General Coordinator of Open Innovation
I2	Enap Challenges Platform	Project Manager
I3	Serpro Ventures	Superintendent of Corporate Architecture, Platforms and Cloud
I4	Serpro Ventures	Superintendent of Business Strategy, Pricing and Innovation

fering support, training, and infrastructure to structure these challenges, fostering tech-driven solutions for government efficiency. For this OI process, ENAP has developed a toolkit consisting of seven steps, organized into three main phases.

1. **Pre-Challenge Launch**: *1) Problem Identification:* The process begins with an analysis to understand the complexity of the problem and its feasibility for OI; *2) Market Interviews:* Before launching a challenge, existing solutions are explored and potential contributions from the private sector are assessed; *3) Challenge Planning:* Defining the format, rules, evaluation criteria, and legal framework.
2. **Challenge Launch:** *4) Dissemination and Participant Mobilization:* The platform is used to publicize challenges to startups, companies, universities, and citizens interested in contributing; *5) Interaction and Co-Creation:* Workshops, hackathons, and other methodologies are employed to foster collaboration between the government and participants.
3. **Post-Challenge:** *6) Solution Development and Validation:* The public agency evaluates the submitted solutions and may contract or incubate the best proposal; *7) Scaling and Implementation:* If the solution is successful, it can be expanded to other areas of government.

4.2. Serpro Ventures

The second unit of analysis, known as Serpro Ventures is a structured innovation program led by SERPRO, a publicly owned private-law company. It fosters collaboration with innovation hubs, universities, and ICTs, engaging public servants, researchers, startups, and society in co-creating technological solutions for public agencies. To implement OI, SERPRO applies various strategic approaches.

1. Web Platform: Registers opportunities and partnerships;
2. Hackathons: Explore new ideas and foster creativity;
3. Prototyping and Design Thinking Sessions: Shape innovative solutions;
4. Public Calls: Ensure transparency and create opportunities for diverse participants;
5. Incentive Programs: Provides vouchers for startups to test SERPRO's APIs.

4.3. Dimensions

In this section, we present the main findings of the thematic analysis, organizing them into five core dimensions (i.e., themes): 1) **practices** – a set of efforts, resources, and strategies applied to enable OI processes; 2) **stakeholders** – internal and external participants who play essential roles in the initiative; 3) **enablers** – internal and external elements that can drive project implementation; 4) **barriers** – obstacles that hinder project execution; and 5) **technology** – the role of technological tools in the development and implementation of the initiative.

These dimensions were defined based on a systematic literature review on OI in the public sector (de Lima Júnior et al., 2024), previously conducted to identify conceptual patterns and theoretical gaps in recent scholarly work. The adoption of these categories provided a robust theoretical framework for the empirical analysis, guiding data coding and case triangulation. To further illustrate the findings, we adapted the C1 (Enap Challenges Platform) and C2 (Serpro Ventures) taxonomy, offering a more structured interpretation of the collected data.

4.3.1. Practices

The "practices" theme in this study comprises 41 characteristics (Table 2), with 36 identified through field research and 5 from a systematic literature review (de Lima Júnior et al., 2024). To organize them, 8 overarching

sub-themes were created. Both Enap Challenges Platform and Serpro Ventures relied on structured methodologies, such as stage gate and toolkits, along with specific tools to streamline the innovation process (I1, I2, I3, I4). Legal frameworks played a crucial role in establishing a favorable environment for innovation, supported by NDAs, licenses, contracts, and patents to ensure protection and compliance (I1, I2, I3). Capacity-building was a key investment in both initiatives, incorporating mentorships, workshops, webinars, training, and interactive sessions to promote continuous learning (I1, I2, I3, I4). Table 3 presents the general characteristics of the approach dimension for both initiatives.

Tab. 2 – Practices being employed in both initiatives

#	Practices	C1	C2	#	Practices	C1	C2

Tab. 3 – Characteristics of the "Approaches" dimension

Feature	Sample quotes	Interviewee
Legal Instruments	"(...) having regulations and laws that made this easier (...) is important from the government's perspective."	I4
Innovation Management and Processes	"(...) within the toolkit, it is a very important step"	I2
Intermediation	"(...) ENAP is an intermediary (...) for the government."	I1
Train the Participants	"We initially selected a small group (...) these individuals received extensive training"	I4
Legal Support	"(...) we invested in a consulting firm to structure the regulations for our process, ensuring security."	I4
Engaging External Stakeholders	"(...) we always seek partners that can reach different regions of Brazil, ensuring national participation."	I1

4.3.2. Stakeholders

The data analysis reveals that, for this study, the "stakeholders" dimension consists of 22 main types of stakeholders. Among these, 8 emerged from direct engagement with participants (3, 8, 9, 10, 15, 16, 17, and 18), while the remaining 14 (1, 2, 4-7, 11-14, and 19-21) were identified through a systematic literature review (de Lima Júnior et al., 2024). The data are presented in Table 4.

Startups played a central role in Enap Challenges Platform, while Serpro Ventures, though focused on established companies, also engaged with promising startups to stimulate innovation (I1–I4). Both initiatives maintain connections with universities, with Serpro Ventures aiming to deepen research collaborations (I3, I4). Senior management engagement proved critical for decision-making and resource allocation across both cases (I1–I4). Additionally, Serpro Ventures distinguished itself through strong ties with Innovation Hubs, promot-

Tab. 4 – List of Identified Stakeholders

#	Stakeholders	C1	C2	#	Stakeholders	C1	C2
1	Citizens	X	X	12	Intermediaries	X	X
2	Project Council	X	X	13	Joint Venture	X	X
3	Consultant	X	X	14	R&D Laboratory	X	X
4	Companies	X	X	15	Leadership (Senior Management)	X	X
5	Nonprofit Organizations	X	X	16	Internal Agencies	X	X
6	Internal Employees	X	X	17	CSOs	X	X
7	Government	X	X	18	Technology Park	X	X
8	GovTechs	X	X	19	Researchers	X	X
9	Innovation Hub		X	20	Civil Society	X	
10	ICTs		X	21	Startups	X	X
11	Innovators	X	X	22	Universities	X	X

ing knowledge exchange and dynamic collaboration (I3, I4). Table 5 presents the key stakeholders involved in the OI cycles.

Tab. 5 – Sample quotes of the main stakeholders involved

Stakeholder	Sample quotes	Interviewee
Startups	"(...) open innovation is strongly associated with startups, especially in the tech sector."	I2
Private Companies	"(...) some challenges were open to everyone, while others were restricted to companies."	I1
Government	"(...) in our case, the government has primarily acted as a client, the one requesting the challenge."	I1
Leadership (Senior Management)	"(...) senior management must truly believe in this."	I4
CSOs (Civil Society Organizations)	"(...) we work closely with CSOs and have even signed a cooperation agreement with them, including the Impact Hub."	I2
Universities	"(...) we are entering a new phase where we aim to bring certain stakeholders, especially universities, closer to our ecosystem."	I3
Citizens	"(...) any individual or team can register and submit their solution or proposal."	I1

4.3.3. Enablers

The case study identified key enablers and barriers that influenced the initiatives. A total of 20 enablers were classified, with 10 derived from the systematic literature review (1, 2, 5, 8, 11, 13, 15, 17, 19, 20) and 10 from interview insights (3, 4, 6, 7, 9, 10, 12, 14, 16, 18), reflecting practical experiences. The complete list is presented in Table 6.

Tab. 6 – List of identified enablers

#	Enablers	C1	C2	#	Enablers	C1	C2
1	Open Data	X	X	11	Challenge Promotion	X	X
2	Relaxed Environment	X		12	Innovation Ecosystem	X	
3	Administrative Support	X		13	Empowerment of People	X	X
4	Support from Senior Management	X	X	14	Stakeholder Engagement	X	X
5	External Stakeholders	X		15	Ease of Hiring (Initial Stages)	X	X
6	Training for Participants	X	X	16	Infrastructure		X
7	Success Cases	X	X	17	Relevant Legislation	X	X
8	Collaboration	X	X	18	Financial Resources	X	X
9	Communication	X		19	Technology	X	X
10	Organizational Culture	X	X	20	Transparency	X	X

Relevant legislation provided the legal foundation for OI, ensuring compliance and security (I1, I4). Senior management support was crucial for institutional backing, resource allocation, and strategic alignment (I3). Training enhanced innovation capacity, while successful case studies helped reduce resistance and inspire new approaches (I1, I2, I3, I4). Challenge promotion played a key role in engaging startups, companies, and universities. Strengthening ecosystem connections, including partnerships with innovation hubs and research centers, fostered collaboration and a dynamic innovation environment (I1, I2).

Tab. 7 – Sample quotes of the main enablers

Enablers	Sample quotes	Interviewee
Relevant Legislation	"(...) the legal framework already incorporates approaches such as solution acceleration, institutional arrangements, and the use of the startup legal framework for contracting solution testing."	I1
Financial Resources	"(...) more than 20% of the company's revenue now comes from the products we have launched in recent years."	I4
Successful Case Studies	"(...) our main reference, in fact, is challenge.gov."	I1
Senior Management Support	"(...) having leadership invested in making things happen was very important."	I1
Ease of Contracting	"(...) any contracting process is now easier than it used to be, and open innovation-related contracts are relatively straightforward."	I2

4.3.4. Barriers

The analysis identified 18 barriers affecting the initiatives during the operational phase. Among them, 5 emerged from the systematic literature review (3, 5, 13, 14, 17), while 13 were identified through interviews (1, 2, 4, 6-12, 15, 16, 18). Table 8 presents the main obstacles that had to be overcome for successful implementation.

Tab. 8 – List of identified barriers

#	Barriers	C1	C2	#	Barriers	C1	C2
1	Cultural Aspects	X	X	10	Lack of Time	X	
2	Barriers to Engagement	X		11	Limitations	X	X
3	Legal Barriers	X	X	12	Financial Constraint		X
4	Organizational Barriers	X	X	13	Political Mandate	X	X
5	Bureaucracy	X	X	14	Personal Data Privacy		X
6	Conflicts		X	15	Lengthy Process	X	X
7	Engaging External Agencies	X	X	16	Resistance	X	X
8	Lack of Capacity	X	X	17	Technical Restrictions	X	X
9	Lack of Engagement	X		18	Risk	X	X

A key risk in public sector innovation is the fear of accountability among public servants for procedural failures (I1, I2, I3, I4). While bureaucracy ensures transparency, it often hinders innovation (I1, I2, I3, I4). Additionally, cultural resistance, rooted in hierarchical and traditional structures, further challenges change (I1, I2, I3, 11). Table 7 summarizes the main barriers faced during implementation.

Tab. 9 – Sample quotes of the main barriers

Barriers	Sample quotes	Interviewee
Risk	"(...) the public sector has a strong aversion to risk, including fear of making mistakes and then being penalized for them."	I1
Bureaucracy	"(...) open innovation challenges take a long time to materialize because they must go through all these phases."	I1
Political Mandate	"(...) every political transition requires a significant amount of time for realignment—adjusting priorities and refocusing innovation efforts."	I4
Resistance	"(...) when the public call needs to be launched by the institution itself, that's when we encounter resistance to innovation."	I1
Lack of Capacity	"(...) we often work with teams that have never done this before, or perhaps have minimal experience—which is why they seek us out—but they are not experts in open innovation."	I1

4.3.5. Technology

Technology played a fundamental role in driving these initiatives forward. Regarding its influence on these actions, 16 relevant aspects were identified. Among them, 7 were highlighted during the interviews (5, 6, 8,

11, 12, 14, and 15), while the remaining 9 were extracted from the systematic review analysis (1-4, 7, 9, 10, 13, and 16). Table 10 presents the roles played by technology in these initiatives.

Tab. 10 – List of identified Technology Roles

#	Roles	C1	C2	#	Roles	C1	C2
1	Open Data Provisioning	X	X	9	Intermediating the Innovation Process	X	
2	Development of New Technologies	X		10	Social Media Monitoring	X	X
3	API Provisioning	X	X	11	Process Optimization	X	X
4	Provision of Online Services	X	X	12	Enables Transparency	X	
5	Dissemination	X	X	13	Facilitates Communication	X	
6	Documentation	X	X	14	Remote Process	X	X
7	Process Facilitation	X	X	15	Online Meetings		X
8	Innovation Support Tools	X	X	16	Support for Collaborative Activities	X	X

Table 11 highlights key technology roles in OI. Technological tools enabled continuous collaboration among stakeholders (I2, I4). Dissemination expanded initiative reach and engagement (I1, I3). Technology also improved transparency, ensuring all process stages were documented and accessible (I2, I3).

5. Discussion

5.1. Units of analysis comparison

Based on the five themes of this study, the following similarities can be highlighted in both approaches:

- **Practices:** Both Enap Challenges Platform and Serpro Ventures have institutionalized OI in the public sector through legal frameworks and tailored methodologies (I2, I3, I4), reflecting distinct intermediation logics—open dissemination in the case of ENAP, with online-accessible toolkits, and restricted collaboration in Serpro Ventures, based on stage-gated processes with confidential partners (I3, I4). The nationwide reach of both initiatives reinforces their role as federal intermediaries, aligning with discussions on multilevel innovation governance (Figenschou et al., 2024; Mu and Wang, 2022; Palumbo et al., 2023; Pinto et al., 2024). The emphasis on capacity-building—through training in ENAP and professional development in Serpro Ventures —contributes to the sustainability of innovation (Al Maazmi et al., 2024; Edelmann et al., 2023).
- **Stakeholders:** Both initiatives position public agencies as their primary beneficiaries (I1, I2, I3, I4), reinforcing their intermediary role in public sector-oriented innovation networks (Bakici et al., 2013). Active support from senior management (I1, I3, I4) underscores the importance of institutional leadership as a key enabler of DT (Mergel et al., 2019). While academic partnerships are still in the process of consolidation (I1, I3, I4), they reflect an effort to bridge science and public policy design (Ferraris et al., 2020; Palumbo et al., 2023). In parallel, engagement with CSOs (I2, I3) strengthens participatory models of governance (Figenschou et al., 2024).
- **Influencing Factors:** Access to financial resources is critical for investments in platforms, licenses, and experimental initiatives (I1, I2, I3, I4), as highlighted in studies on the sustainability of public innovation (Al Maazmi et al., 2024; Georghiou et al., 2014). Participation in innovation events and forums (I1, I2, I4) serves as a strategy for stakeholder engagement and institutional legitimation (Bogers et al., 2018). Nevertheless, structural barriers such as bureaucratic rigidity and risk aversion continue to hinder collaboration with startups and technology firms (I1, I2, I3, I4).

Tab. 11 – Sample quotes of the main technology roles

Roles	Sample quotes	Interviewee
Open Data	"When data is already open, that is the ideal scenario."	I2
Innovation Support Tools	"(...) using Discord to maintain communication with registered teams, networks—every one of our challenges has a technological component."	I1
API Availability	"(...) we have already used APIs and platforms to support technology development."	I1
Supporting Collaborative Activities	"(...) we rely heavily on technology, using Miro for virtual events that require intense collaboration."	I3

- **Role of Technology:** Technology plays a central role by enabling interoperability between systems through APIs (I1, I3) and facilitating synchronous and asynchronous interactions via platforms such as Discord, Zoom, YouTube, and WhatsApp (I3, I4). These tools enhance collaboration and transparency, contributing to more open digital ecosystems (Gong et al., 2020; Verhoef et al., 2021). The dual role of technology—as both technical infrastructure and a sociotechnical mediation mechanism—aligns with contemporary perspectives on DT in the public sector (Tiach and Abdellatif, 2023; Vial, 2019).

Digital Transformation, driven by OI, enhances engagement, collaboration, and strategic partnerships. For its effective implementation, it is essential to address aspects such as bureaucracy, infrastructure, organizational culture, resource allocation, and capacity building, ensuring sustainable and impactful progress.

5.2. Related work

In this section we position our results compared to a summary of findings from two recent literature reviews on public OI: Mu and Wang, 2022 focused on barriers for OI while Palumbo et al., 2023 brings a broader perspective that cover similar themes as we had.

Some of the barriers we identified to OI align with the barriers identified by Mu and Wang, 2022. These similarities illustrate how traditional barriers to OI persist across digital and administrative domains. E.g., **Technical Restrictions** pose a significant hurdle, closely mirroring the broader challenge of Technical Difficulties, which includes issues related to system service quality, infrastructure, and professional expertise. Similarly, **Lack of Capacity**, **Organizational Barriers**, and **Bureaucracy** reflect the problem of Limited Organizational and Political Capacities, where rigid structures and insufficient resources hinder the adoption and implementation of OI.

Many of the OI practices we identified align with those found in the literature (Palumbo et al., 2023). For instance, **Governance and Strategy**, which includes **Align Expectations**, **Innovation Strategy**, and **Strategic Planning**, corresponds to Public-Private Partnerships (PPPs) and Public-Private-People Partnerships (PPPPs), as both emphasize structured collaboration frameworks between government entities, private organizations, and civil society to drive innovation. **Institutional Initiatives** and **Internal Regulations** also support Open Government Data Initiatives, as they establish the regulatory frameworks necessary for data-driven transparency and innovation. Similarly, **Engagement and Collaboration**, which includes **Bring Stakeholders Closer**, **Collaboration**, and **Partnerships**, aligns with Co-Creation Models, where multiple actors actively participate in the design and implementation of innovative solutions.

The key **stakeholders** of POI mapped by Palumbo et al., 2023 include government entities and public administrations, private sector companies, academia and research institutions, non-governmental organizations (NGOs) and third-sector organizations, and citizens and civil society. These are are also similar to what we mapped.

Similarly, our identified POI enablers align with those from Palumbo et al., 2023 as well. For example, **Open Data** corresponds to technological infrastructures, such as open data platforms and digital collaboration tools, as both emphasize the role of accessible and interoperable data in fostering innovation. Similarly, **Support from Senior Management** and **Administrative Support** align with financial and relational support from public sector entities, highlighting the importance of leadership and institutional commitment in sustaining innovation efforts. The role of **Stakeholder Engagement**, **Collaboration**, and **External Stakeholders** corresponds to trust-building mechanisms to enhance stakeholder engagement, as both recognize the necessity of fostering meaningful relationships and cooperation across sectors. Likewise, **Training for Participants** and **Empowerment of People** align with knowledge-sharing networks to support cross-sector partnerships, ensuring that stakeholders have the necessary skills and opportunities to contribute effectively.

Our findings highlight the critical role of technology in enabling **Open Data provisioning**, which aligns with Palumbo's (Palumbo et al., 2023) concept of Data-Driven Innovation, ensuring that stakeholders can access government-held information to drive new solutions. The **Development of New Technologies** and **API Provisioning** directly contribute to Facilitating Knowledge Flows, fostering continuous inflows and outflows of knowledge that enhance cross-sectoral collaboration. Additionally, **Provision of Online Services** and **Dissemination** are key in Transparency and Open Governance, ensuring accessibility to innovation-driven ini-

tiatives. The **Intermediating the Innovation Process** and **Innovation Support Tools** closely match Orchestrating Multi-Actor Innovation, as they enable coordination among diverse stakeholders within a structured ecosystem.

Only one comparable study focuses on the municipal level (de Lima-Junior et al., 2024), revealing several shared findings. Both highlight the **importance of legal and methodological frameworks**, the need for **stakeholder engagement** and high-level administrative support, and the relevance of **university partnerships** and **collaboration with civil society** in fostering innovation. They also identify **funding** as essential for sustaining initiatives. Common barriers include **bureaucracy and risk aversion**, which hinder participation. Finally, both studies recognize **technology as a facilitator** of OI, particularly through APIs, digital platforms, and open data.

This study contributes to the field of digital government by deepening the understanding of the role of federal public institutions as intermediaries in OI ecosystems—a topic still underexplored in the specialized literature. Its originality lies in the comparative analysis of cases operating under different institutional configurations but sharing the strategic function of articulating multiple actors, fostering interorganizational collaboration, and enabling distributed DT. The relevance of the phenomenon under study is underscored by the growing challenges faced by governments in contexts marked by resource scarcity, complex demands, and the need for agile and collaborative solutions. The research offers theoretical and empirical insights to rethink governance models, expand institutional capacities, and strengthen data-driven and participatory public policies.

5.3. Limitations

This study has some limitations. First, analyzing only two cases may limit the generalizability of the findings, as they may not fully capture the diversity of experiences in similar contexts. Second, the thematic analysis was primarily conducted by a single researcher, introducing potential bias despite later discussions with two others to enhance rigor. Future research could expand the number of cases and involve more analysts to enhance the reliability of findings and reduce subjectivity. Moreover, it is important to investigate the role of other federal institutions that adopt different models of intermediation, as well as to analyze the impact of such initiatives at subnational levels of government, contributing to a more comprehensive understanding of open innovation in the public sector.

6. Conclusions

The empirical investigation conducted in this case (Enap Challenges Platform and Serpro Ventures) highlights innovative pathways and promising strategies for DT in federal agencies. The incorporation of OI has driven significant changes in organizational culture, resulting in substantial improvements in the quality of public services provided to citizens.

The analysis of data obtained from both initiatives reveals strategic actions aimed at improving public services and strengthening the relationship between government and society through OI. The study emphasizes the active participation of various stakeholders in public administration, highlighting the essential role of citizens. As key drivers of DT, citizens exert a direct influence on the adoption of innovative practices by government agencies. In this regard, positioning citizens at the center of the public debate is fundamental to understanding their expectations and needs concerning urban development. This approach reinforces a strategic direction focused on creating innovative solutions through collaboration, ensuring that public demands are met more effectively.

Abstract. The development of Business Intelligence (BI) tools is essential for improving the efficiency and quality of services in public and private organizations. However, public institutions, especially at the subnational level, often face challenges due to legacy systems that complicate effective data utilization. This study focuses on a subnational public institution, the Court of Auditors of the State of Pernambuco (TCE-PE), which previously relied on a dashboard with several limitations, including usability issues, data inconsistencies, and maintenance complexities due to its dependence on multiple SQL Server database views. This study presents the development of a new dashboard, designed using an agile methodology, to centralize data transformations within the BI tool. The proposed solution focuses on the Accountability process, aiming to enhance data consistency and improve performance monitoring. The development process was structured into four key phases: Problem Identification, Planning and Requirements Collection, Design and Development, and Validation and Testing, ensuring a systematic and iterative approach to address the institution's needs. The new system utilizes Qlik Sense, eliminating dependency on SQL Server views and allowing real-time analysis through interactive dashboards. The solution overcomes prior limitations, providing faster, more accurate, and reliable analyses aligned with the institution's strategic objectives. By improving flexibility, usability, and data reliability, this initiative not only serves as a reference for other subnational institutions in Brazil but can also be adapted as a model for organizations operating in diverse contexts worldwide.

Research paper, DOI: https://doi.org/10.59490/dgo.2025.966

1. Introduction

Over time, the volume of information has grown exponentially, particularly in the public sector, which deals with data essential for decision-making and activity monitoring. This growth has made the public sector increasingly aware of the potential value that can be derived from the data it generates (Munné, 2016). In this context, there is a rising demand for Business Intelligence (BI) tools, which stand out as fundamental strategies for organizing and structuring data, facilitating information management, and supporting data-driven decision-making (Negash, 2004).

The use of dashboards in the public sector has proven to be an effective strategy in the context of governmental digital transformation (Andrade et al., 2023), especially in the face of growing challenges in managing large volumes of data and the pursuit of greater transparency and operational efficiency. For instance, serves a

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

variety of purposes, from performance monitoring to policy formulation and public engagement (Matheus et al., 2020). These dashboards provide flexibility by offering both broad overviews and specific insights, promoting transparency and detailed analysis of critical events. However, for these dashboards to reach their full potential, it is essential to ensure the quality of the data used, considering aspects such as granularity, timeliness, and accuracy. Inadequate use or lack of optimization of dashboards can compromise the efficiency of monitoring critical processes and hinder strategic decision-making based on reliable data (Matheus et al., 2020).

Within this context, the Court of Auditors of the State of Pernambuco (TCE-PE) has adopted BI tools to monitor and analyze data related to its activities, with a particular focus on the Process Monitoring Dashboard. However, the dashboard faced limitations that compromised both its usability and the consistency of the information presented. These challenges were primarily associated with the integration of multiple views used to extract and transform data, which reduced the dashboard's efficiency and made its maintenance more difficult. Additionally, the sharing of these views across departments, which applied different data treatments, led to the emergence of conflicting information. As a result, there were obstacles to the accurate visualization of key indicators essential for tracking and improving organizational processes.

The limitations of the previous system resulted in significant impacts, such as delays in indicator analysis and difficulties in implementing essential improvements for monitoring critical processes. These issues were primarily caused by information fragmentation, challenges in adopting new technologies, and difficulties related to data integration and quality. To ensure the effectiveness of BI dashboards, it is essential to overcome these limitations, focusing on proper design and data quality, which are critical factors for promoting transparency and accountability (Matheus et al., 2020). Furthermore, the implementation of BI systems requires a transformation in technological infrastructures, overcoming the barriers of legacy systems and meeting the demand for dynamic and timely information (Mix, 2016).

This study aims to present the development process of a new dashboard for process monitoring, focusing on the "Accountability" modality at TCE-PE. The study highlights the benefits and limitations of the proposed solution, which was developed in Qlik Sense to address issues in the previous system, such as usability problems, data inconsistencies, and reliance on SQL Server views. By enhancing the consistency, efficiency, and reliability of analyses through interactive and real-time visualizations, the solution contributes to optimizing the institution's internal processes and aligning with its strategic goals. Additionally, this study serves as a reference for subnational public organizations, promoting best practices in the use of BI tools to improve efficiency, transparency, and decision-making support within the broader context of digital government and the specific challenges of digital transformation in the public sector.

This article is structured as follows. Section 2 presents related works. Section 3 discusses the theoretical foundation on process management and monitoring in the public sector, as well as the tools and technologies employed. Section 4 details the methodology adopted in the development of the new dashboard. Section 5 describes the main implementations of the dashboard. Section 6 presents the analysis and interpretation of the results obtained. Finally, Section 7 discusses the conclusions and future perspectives of this study.

2. Literature Review

In both public and private organizations, numerous studies explore the use of BI tools for data monitoring and analysis to support decision-making. In the private sector, Widjaja and Mauritsius (2019) addressed the implementation of a BI system at *Indomobil*, one of the leading automotive companies in Indonesia. The study aimed to develop a performance dashboard using the Power BI tool to facilitate the analysis of operational data at the strategic management level. The implementation followed four stages: analysis, design, planning, implementation, and control. The results indicated that the dashboard implementation provided a better understanding of the company's operations, enabling efficient monitoring and identification of areas requiring improvement.

The study by Sanabia-Lizarraga et al. (2024) was conducted at the Agro-logistics Observatory of the Sonora Institute of Technology (ITSON), aiming to support the analysis of Mexico's agricultural foreign trade. The objective was to develop an interactive Power BI dashboard for analyzing Mexican agricultural exports, enabling the visualization and comparison of export and import data to support decision-making for commercial and academic purposes. To achieve this, the Cross-Industry Standard Process for Data Mining (CRISP-DM)

methodology was adopted, involving the collection and cleaning of data from various sources and a modeling process that integrates geospatial data and economic classifications. The developed dashboard provided a detailed visualization of the Mexican agricultural trade scenario and was well-received by its stakeholders for its usefulness in strategic decision-making for the agricultural sector.

In the public sector, Samad and Setyabudhi (2023) identified the need for software to improve and facilitate police services at the Integrated Police Service Center (SPKT). The data used were still processed, according to information needs, using Microsoft Office applications (Word and Excel), which had limitations. Thus, the authors designed a public service administration application to assist in managing this data. The application includes a dashboard that presents important information, combined and organized on a single screen, allowing for quick visualization. The results of developing the public service administration dashboard using the waterfall model involved nine tables to support the application and enabled easier data retrieval. Among the limitations of the work, the authors highlight that the solution is restricted to administration and employee pages and does not support online services for email. Additionally, they emphasize the need to increase human resources to support the new system.

Given the recent increase in the number of refugees due to the war in Ukraine, Sprenkamp et al. (2023) proposed a tool for the Swiss government to manage refugee needs. The authors aimed to demonstrate how modern Natural Language Processing (NLP) techniques can be applied to identify refugee needs from large volumes of textual data. To achieve this, they used the Design Science Research approach, which involved semi-structured interviews with stakeholders to define design requirements and develop the "Refugees to Government" (R2G) application, based on topic modeling applied to Telegram data. This application analyzes public Telegram messages, making them available on a dashboard where users can navigate the data and view the main refugee needs in an organized manner. The results show that the system is effective in identifying refugee needs and can be used to complement public policies. However, the study raises ethical challenges related to refugee privacy and risks of misuse of the tool.

Also in the public sector, Vila et al. (2018) highlight the use of information visualization tools to enhance governmental decision-making. The authors proposed the design of a dashboard that integrates visualizations built from open data provided by the Municipality of Bahía Blanca, Argentina. This dashboard was divided into six areas and aims to provide an overview of the most relevant information about the city, facilitating high-level data analysis for the mayor and other authorities. The proposed dashboard is capable of providing a broad overview of the city, presenting information on the most important areas related to policy. However, the authors argue that dashboards are unable to portray cities as they are in real life due to their reliance on open data, which must be made available by government agencies.

The development of the BI dashboard for the TCE-PE differs from previous studies due to its focus on oversight and transparency in public administration. While works such as (Sanabia-Lizarraga et al., 2024; Widjaja & Mauritsius, 2019) address performance optimization in the private sector, and others like (Samad & Setyabudhi, 2023) deal with specific public services, this study aims to enhance the control of administrative processes and accountability, ensuring greater reliability and efficiency in data management. Despite advancements in BI tools, several challenges persist, including data fragmentation due to reliance on multiple sources (Samad & Setyabudhi, 2023; Sanabia-Lizarraga et al., 2024), limited applicability of solutions without a broader governance approach (Samad & Setyabudhi, 2023; Vila et al., 2018), and concerns regarding transparency and data reliability in decision-making (Sprenkamp et al., 2023; Vila et al., 2018). To address these issues, the proposed dashboard uses Qlik Sense technology, contrasting with the predominant use of Power BI, to integrate and centralize information, reducing fragmentation caused by multiple SQL Server views. This approach strengthens public governance by providing a unified and accessible view of data, serving as a reference for other institutions seeking to improve their management through BI solutions focused on transparency and efficient oversight.

3. Background

3.1. Process Management and Monitoring in the Public Sector

All organizations, whether public, private, or non-profit, need to manage a series of processes (Dumas et al., 2018). Thus, it is necessary to adopt an effective strategy for managing their business processes. A business

process can be defined as a set of interrelated events, activities, and decisions involving various actors and objects, aimed at delivering a valuable outcome to at least one customer (Dumas et al., 2018). In the context of the public sector, business processes are adapted to address the complexity of government regulations and the diversity of stakeholders involved. Effective management of these processes is crucial for improving organizational effectiveness and efficiency, especially when based on cross-functional processes (Gulledge Jr & Sommer, 2002).

However, the degree of implementation and maturity of business process management in public institutions remains relatively low, and the willingness to share knowledge on the topic is limited (Ahrend, 2014). The effective adoption of BPM is often hindered by the lack of integration of its principles into the organizational culture, resulting from both the absence of competitive pressure for rapid changes and the inherent bureaucracy in decision-making processes (Dumas et al., 2018). Additionally, public organizations also face challenges related to multiple stakeholders and cross-cutting portfolio objectives, as they deal with a broader and more complex variety of clients compared to private organizations (Tregear & Jenkins, 2007).

To improve the quality of services offered, proper monitoring of business processes is necessary (Fioretto & Masciari, 2024). Process monitoring reflects the actual performance of planned activities and is essential for good governance, facilitating accountability and transparency (Mohamed & Kulmie, 2023). Through the data collected, it is possible to identify bottlenecks, recurring errors, or deviations from the expected behavior of processes, enabling the adoption of corrective actions (Dumas et al., 2018).

Like other public institutions, the TCE-PE also requires constant monitoring of its business processes. Playing a key role in overseeing public administration, the TCE-PE is responsible for analyzing documentation provided by public institutions, conducting audits, evaluating the legality of managers' actions, and verifying the cost-effectiveness of expenditures and their compliance with government guidelines and programs (TCE-PE, 2025a). In this context, the use of monitoring tools to assess the efficiency of TCE-PE's business processes is crucial for transparency in the analysis of public accounts. In this regard, the prototype of the process dashboard was developed focusing solely on the "Accountability" procedural modality. This modality was chosen due to its importance to the institution and the large volume of available data on it.

3.2. Monitoring Technologies and Tools

Monitoring technologies and tools are used to track, analyze, and evaluate the performance of data related to processes or activities within an institution. In the public sector, monitoring plays a significant role in enhancing activities, contributing to increased effectiveness and efficiency of services provided to society. These tools enable the identification of deficiencies, the evaluation of trends, and the implementation of best practices. Additionally, they allow for the extension and improvement of processes and services, using appropriate instruments to accelerate continuous performance improvement (Dascalu et al., 2016). This provides public managers with more accurate information for decision-making, directly contributing to greater administrative efficiency and better accountability to society.

One of the standout tools in the field of data monitoring and analysis is Qlik Sense (Qlik, 2025), a modern BI platform widely recognized for its advanced capabilities and versatility (Ceccato, 2023). Its functionalities range from data collection and integration to the creation of interactive visualizations and predictive analytics, making it a powerful solution for both public and private institutions. Among its key features are:

- **Customizable and Interactive Dashboards:** Allows the creation of dynamic dashboards with visualizations tailored to the needs of different audiences and purposes, promoting detailed analysis and informed decision-making.
- **Integration with Multiple Data Sources:** Supports data from various sources, such as spreadsheets, SQL databases, XML files, and cloud systems, centralizing information for efficient analysis.
- **Scalability and Flexibility:** Serves small teams to large organizations, allowing adaptations for specific scenarios and ensuring relevance in different organizational contexts.
- **Advanced and Predictive Analytics:** Provides tools for scenario simulations and pattern identification, aiding in anticipating trends and defining more assertive strategies.

Figure 1 illustrates these characteristics in a simplified manner. Data can be extracted from various sources, transformed, and loaded to be presented in dashboard format, in a process known as Extraction-Transformation-Loading (ETL). ETL plays an essential role in data integration and transformation, ensuring

the quality, consistency, and reliability of the analyzed information (Venkateswarlu & Vasista, 2023). Furthermore, the implementation of robust internal controls during each phase of ETL is crucial to prevent errors and ensure data integrity, allowing analyses and decisions to be based on reliable and up-to-date information (Dingre, 2023).

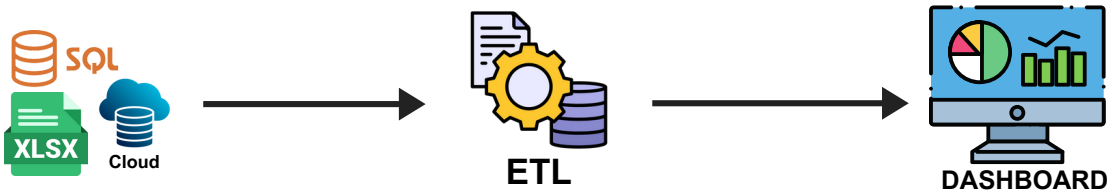

Fig. 1 – Representation of the ETL Process in the context of data integration.

4. Research Method

The development of the new dashboard was carried out collaboratively, using concepts derived from agile methodologies, as described by (Al-Saqqa et al., 2020). These concepts aim to ensure the delivery of a high-quality product within reduced timelines and with optimized resources, aligning with the dynamic needs of the project and promoting continuous adaptability. In this context, the development cycle was adjusted to implement an incremental process with continuous deliveries and feedback. Each increment was subjected to testing and validation, fostering efficient communication among stakeholders and ensuring continuous validation of the product as new functionalities were added. The activities followed a pre-established schedule, structured into four main stages, as shown in Figure 2: Problem Identification, Planning and Requirements Gathering, Design and Development, and Validation and Testing. These stages are detailed below.

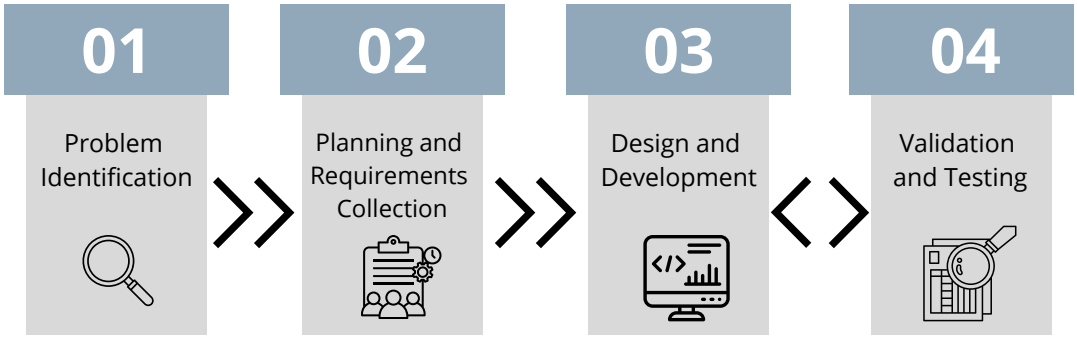

Fig. 2 – Adopted methodology.

4.1. Problem Identification

In this phase, an analysis was conducted to identify the problem to be addressed and the organization's needs. This process involved identifying causes and effects, understanding the nature of the problem, and considering potential constraints. The analysis was primarily based on the previous dashboard and existing requirement documents to understand its deficiencies and limitations. The goal of this stage was to ensure that the proposed solutions not only meet the identified needs but are also effective, feasible, and aligned with the organization's strategic objectives.

Although functional, the process dashboard previously used by the Process Office of TCE-PE had issues that compromised its usability and the consistency of the information presented. Additionally, the dashboard included indicators that were no longer relevant to the sector, while essential indicators were not addressed. The data feeding this dashboard were processed and filtered externally, through the extraction, treatment, and filtering of multiple views from various SQL Server databases.

As a consequence of this chain of views, the dashboard's efficiency was reduced, and data consistency was compromised. Furthermore, these views were shared across various departments, which applied different

types of data treatments, making maintenance difficult and facilitating the emergence of conflicting information. These issues hindered the accurate visualization of the indicators necessary for monitoring and improving the organization's processes. Thus, it became necessary to develop a tool to mitigate these problems.

4.2. Planning and Requirements Collection

After identifying the problems, the next step involved planning and requirements collection, including the establishment of a schedule to be followed and the definition of activities for each phase of the development process. This schedule considered the potential constraints identified in the previous stage and the limitations of resources and time that could impact the feasibility of the proposed solutions. The planning was structured based on the schedule, which was divided into three main stages: Requirements Gathering, Process Dashboard Development, and Testing and Validation.

In the Requirements Gathering stage, activities such as identifying indicators for the Overview, Time, and Inventory tabs, defining filters and views, and reviewing and finalizing the requirements document were carried out. Next, in the Process Dashboard Development phase, data treatment, implementation of the Overview, Time, and Inventory tabs, as well as the implementation of filters and views, took place. Finally, in the Testing and Validation stage, specific tests were conducted for each tab, along with performance and usability tests to ensure the system's effectiveness.

The development of the dashboard was estimated to take 371 calendar days, considering the overlap of some stages, which occur simultaneously. This timeline was distributed among the project activities according to their complexity. The Requirements Gathering stage was planned for a total of 225 days, with 60 days allocated to identifying indicators for the dashboard tabs, 30 days for defining filters and views, and 15 days for finalizing the requirements document. The Process Dashboard Development began immediately after the completion of the general tab's requirements gathering, with an estimated duration of 270 days. Data treatment and the implementation of filters and views also occurred during this period, while the implementation of the tabs was divided into 90-day cycles for each one. Testing was conducted immediately after the implementation of each tab, totaling 65 days, with 15 days for individual tests and 20 days for performance and usability evaluation. With the schedule defined and approved by management, the project execution began.

As defined in the schedule, the project started with requirements gathering, which were recorded in a document containing all the necessary information for the dashboard's development, including technical and functional aspects aligned with organizational objectives. The document was developed through weekly meetings between the TCE-PE team, which defined the indicators to be implemented, as well as the filters and dynamic columns needed to improve information visualization.

The document began with a brief introduction, followed by descriptions of the elements that make up the dashboard: dimensions, measure groups (tabs), related views, and filters. Each tab has its own set of measures; however, the filters and the dynamic table are common to all tabs. Thus, the measures for the Overview tab were defined first, followed by the general and complementary filters and the dynamic table. Finally, the requirements for the Time and Inventory tabs were defined, respectively. After defining the requirements for each tab, the document was submitted to management for approval before being forwarded for development.

4.3. Design and Development

The team involved in the development process included internal public servants and outsourced professionals, working collaboratively throughout the process. This stage consisted of two main phases: design, which involves the processes of data extraction, transformation, and structuring, and development, which refers to the creation of the dashboard, ensuring that the requirements established in the documents are met. During the design phase, the preparation and organization of the data required for the system take place, while the development phase involves the construction of functionalities, charts, columns, and visual structures of the dashboard.

The development of the dashboard included a detailed analysis of the previous dashboard, applying reverse engineering to map the origin and sequence of the *views*, identifying the essential source tables. With this information, it was possible to create a code that extracts data directly from the source, eliminating the dependency on *views* in the new system and ensuring greater control over data consistency and quality. After

mapping the data sources, the direct extraction of information from the databases began, eliminating the need for *views*.

With the data properly structured, the development of the dashboard commenced, following an incremental model using the BI tool Qlik Sense *QLIK Sense* (Qlik, 2025). The dashboard was organized into three main tabs: Overview, Time, and Inventory, each designed to meet specific analysis and monitoring needs. The Overview tab provides a general view of the processes, including information on the number of processes that have completed certain procedural stages. The Time tab displays data related to the duration of process stages (current position), while the Inventory tab presents all formalized processes that have not yet completed the execution phase. The implementation of new tabs was planned for future updates, allowing for the continuous growth of the dashboard.

4.4. Validation and Testing

The validation and testing phase was conducted as each tab was implemented, with the goal of verifying whether the developed solution meets organizational needs. For this purpose, a dashboard validation spreadsheet was used, with access shared between the development team and the testing team, which was composed of the same members responsible for the requirements gathering. The spreadsheet facilitates communication between the two teams and speeds up the resolution of potential inconsistencies during the dashboard implementation phase.

When an inconsistency is identified in the dashboard under development, it is recorded in the validation spreadsheet, which contains specific fields to document a detailed description of the issue, include illustrative images, and provide the step-by-step process that led to the error. With this information, the development team can reproduce the issue and implement the necessary correction. Simultaneously, the testing team monitors the resolution status through a field in the spreadsheet that presents the options: Not Implemented, In Progress, Implemented, Discarded, and In Backlog. The spreadsheet also includes a field for observations, used to record important information about the progress of corrections or to justify the discarding of certain issues.

5. Dashboard Development

The system architecture was developed using Qlik Sense, which integrated both the front-end and back-end of the application. This tool was adopted because it is already used institutionally by TCE-PE. Data were extracted from the Electronic Process System (TCE-PE, 2025b), an electronic process platform of TCE-PE, which facilitates the handling of processes, communication of acts, and transmission of procedural documents virtually. The processes are available for public consultation (TCE-PE, 2025c). It is worth noting that the developed dashboard is exclusively for internal use by TCE-PE, as it contains sensitive and restricted information. According to Article 46 of Resolution No. 22/2015 of TCE-PE, only procedural documents of a public nature will be made available for public consultation, except in cases involving confidentiality to protect privacy or public interest (TCE-PE, 2015). Thus, the Electronic Process System seeks to balance public transparency with the security and confidentiality of its internal data.

The data used in the dashboard were extracted from two main databases, which play complementary roles in the system. The first is the **Reading Database**, which contains essential information about the cases, such as nature, session, judgment, deliberation, and redistribution. The second is the **Complementary Database**, which stores additional data such as information about reporters, municipalities, types of modalities, jurisdictional units (UJ), and staff members. Based on these data, the new dashboard was developed with an initial focus on the "Processes" dimension, aligned with organizational goals, in contrast to the previous dashboard, which included the dimensions: Processes, Activities, and Communications. This dimension encompasses data related to electronic processes, which make up the accounting process modality of TCE-PE providing information such as case quantities, duration, deadlines, and more. The dimension was divided into three tabs: Panorama Geral, Tempo, and Estoque.

The Panorama Geral tab aims to provide an overview of the accounting process and allow monitoring of its phases, showing the quantity of cases that have completed a certain procedural phase. The Tempo tab presents data related to the duration of specific steps in the process, and by default, when accessed, it shows data for the

current date. Finally, the Estoque tab consists of all formalized cases that have not yet completed the execution phase, i.e., all ongoing cases on the selected date. Additionally, the developed dashboard offers several key functionalities for process analysis and monitoring at TCE-PE, enabling interactive visualization and real-time data tracking. Some of the implemented features include views, general filters, complementary filters, and a table with dynamic columns.

Each tab of the dashboard presents a unique set of related views. Views are graphical representations of the measures related to a specific perspective, such as the number of cases by year or month. Thus, views refer to how the data will be graphically displayed to the user. Unlike the previous dashboard, the new Process Dashboard presents views more aligned with organizational goals. Specifically, in the Panorama Geral tab, as illustrated in Figure 3, the user can choose from various options to view the data in different ways. It is important to note that some information in the dashboard has been hidden in the figures due to the sensitive nature of the data.

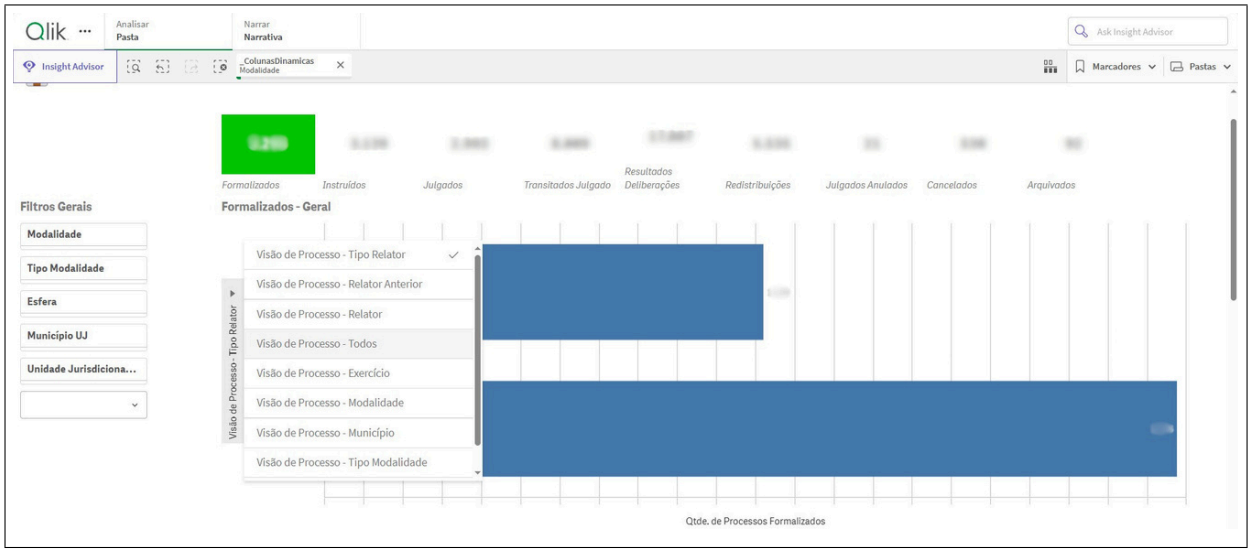

Fig. 3 – Views of the Panorama Geral tab.

The three tabs of the dashboard share a set of interactive filters. These filters apply the criteria selected by the user, adjusting the information displayed in the views. Two types of filters were defined: general and complementary. The general filters include common criteria such as modality, type of modality, sphere, municipality, jurisdictional unit (UJ), exercise, reporter, and process status. The complementary filters offer additional options to further refine the analysis. Figure 4 presents some of these filters.

In addition to the filters, all tabs include a dynamic table. This table presents a representation of the process data that make up the views presented. The table allows the user to add or remove columns dynamically based on their analysis needs. By default, the table displays the following columns: Process Number, Process Link, and Modality, with additional columns that can be added as needed. Figure 5 shows an example of the dynamic table. It is worth noting that the process numbers have been hidden to maintain their confidentiality.

The dashboard was developed to optimize process analysis, offering an intuitive interface and advanced filtering and visualization features. The customization of the dynamic table provides greater flexibility in data visualization, meeting the diverse needs of users. Moreover, the organization of the tabs and filters enhances navigation and allows users to quickly access the most relevant information. With flexibility for future adjustments and expansions, the tool enables continuous monitoring of organizational processes, allowing for greater control and efficiency in operations.

6. Results

The implementation of the new dashboard brought significant improvements to the analysis and monitoring of processes at TCE-PE. To evaluate its effectiveness, tests were conducted with simulated scenarios, demonstrating its ability to provide information more quickly and intuitively. The dashboard allowed managers to

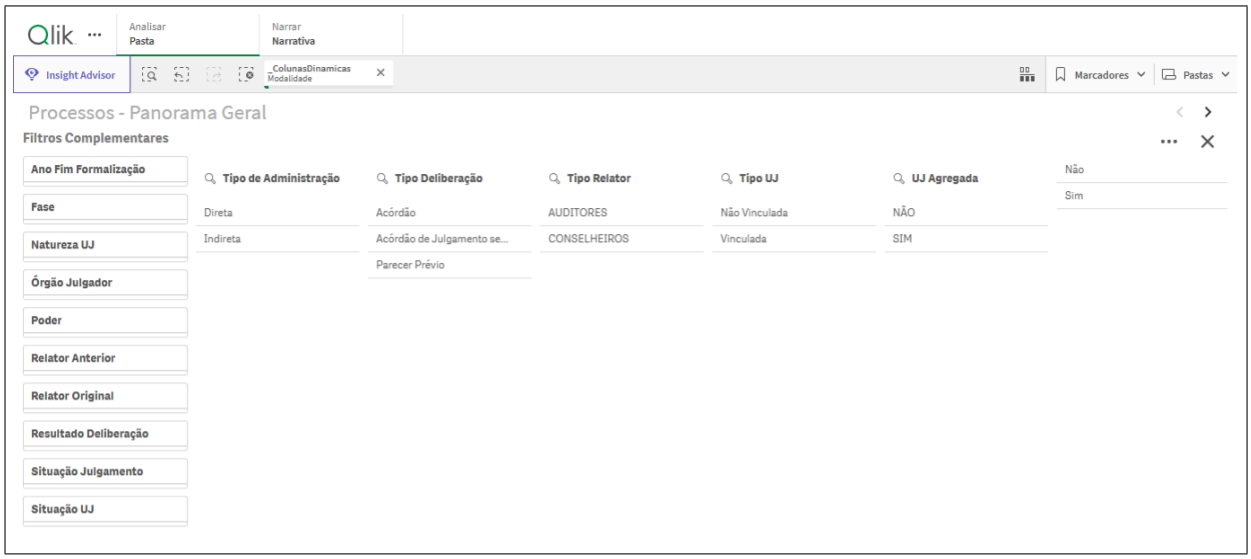

Fig. 4 – List of complementary filters.

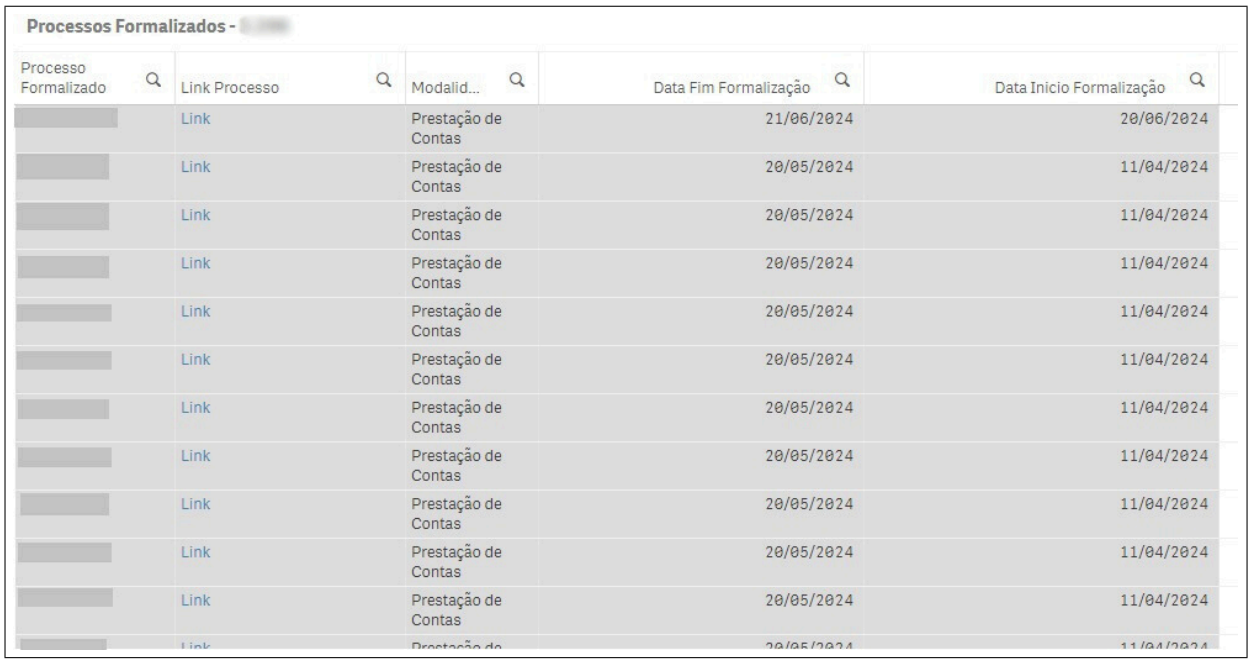

Fig. 5 – Example of a dynamic table.

quickly access essential data, such as the evolution of processes, average processing times, and identified bottlenecks, facilitating strategic decision-making.

Figure 6 presents an example of the Time tab, highlighting the number of processes adjudicated in 2018. In this tab, it is possible to clearly visualize how many processes were completed within and outside the deadline, as well as the timeliness index and the average time, in days, from formalization to adjudication. Additionally, the visualization allows for the identification of the distribution of adjudicated processes over the months of the selected year, providing a more detailed analysis of the processing over time.

Figures 7 and 8 present an example of the Overview tab, filtering the number of formalized processes in the Municipal Sphere with the nature of City Council. In Figure 7, the processes are classified into two modality types: Management and Government. In Figure 8, it is possible to visualize the distribution of processes by year and month of formalization. Figure 9 presents another form of analysis, filtering the Deliberations stage within the Municipal Sphere, considering only processes with the nature of Municipal Prefecture for the year

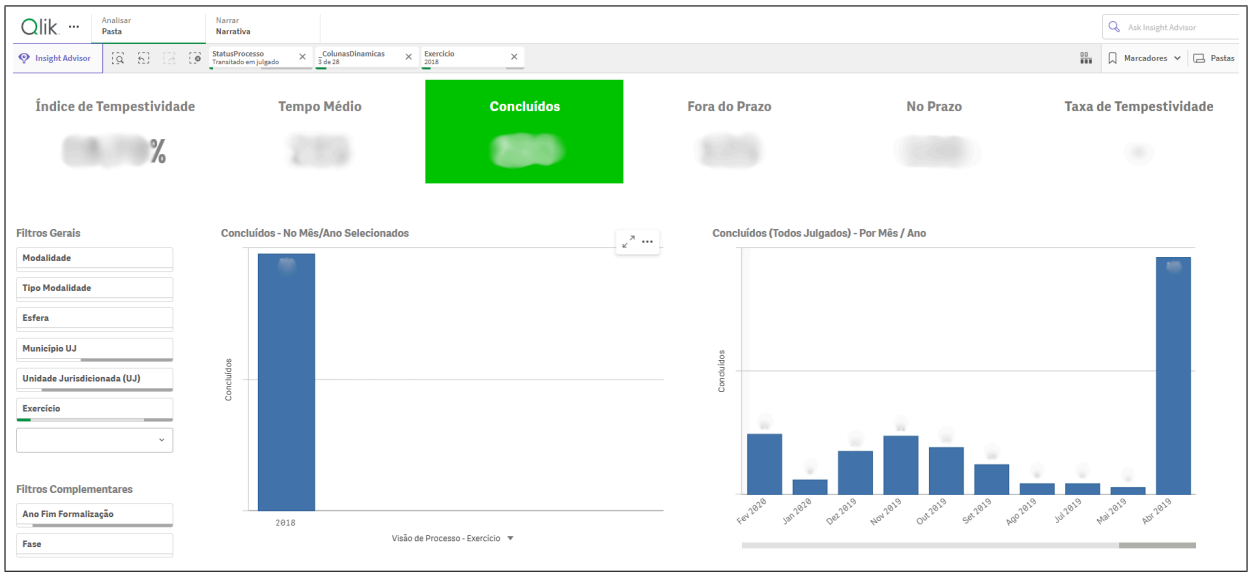

Fig. 6 – Simulation of Adjudicated Processes in the Time Tab.

2024. This visualization allows for the observation of both the total deliberations conducted throughout the year and their monthly distribution.

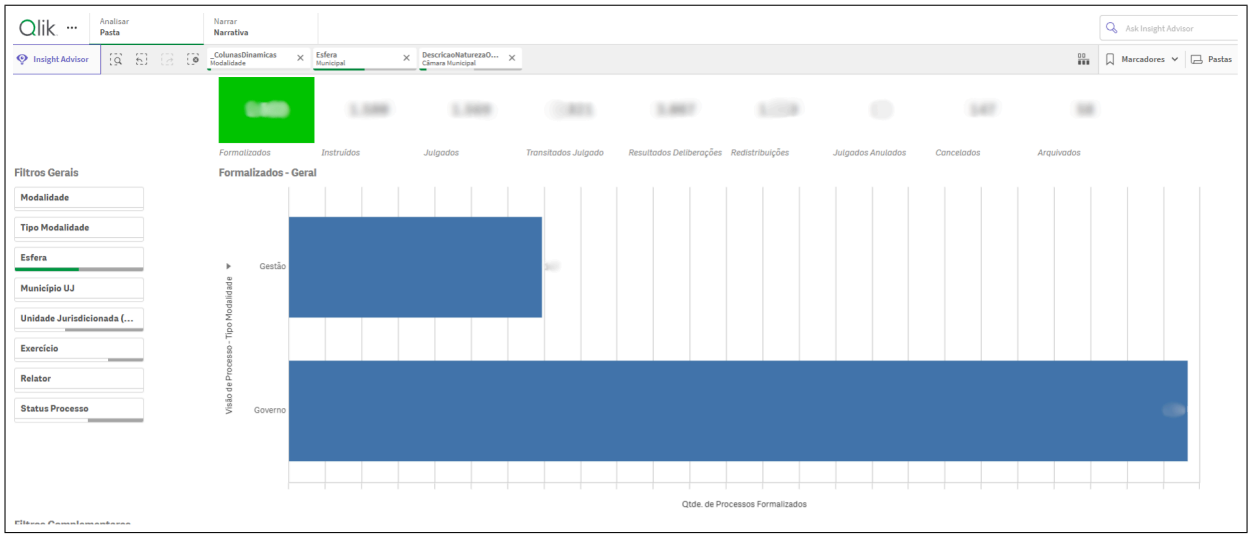

Fig. 7 – Simulation of Formalizations in the Overview Tab, Categorized by Modality.

The implementation of a new, more efficient dashboard aligned with organizational objectives brought significant benefits to the TCE-PE. Among the main benefits achieved are:

- **Greater Efficiency:** The direct extraction of source tables and the optimization of the data flow ensured greater reliability and system performance. The elimination of the use of *views* provided more control over the data, increasing the accuracy of the information presented. Additionally, the centralization of transformations in the Qlik Sense tool reduced processing complexity, making analyses faster and more reliable.
- **Simplified Maintenance:** The entire development and data transformation process was centralized in the Qlik Sense tool, facilitating the identification and correction of errors, the application of improvements, and the understanding of implemented rules.
- **Improved Visualization and Analysis:** The new dashboard presents data interactively and visually clearly, facilitating decision-making and enabling more detailed and intuitive analyses. Additionally, the new filter and view options allow information to be displayed in a customized manner according to user needs.

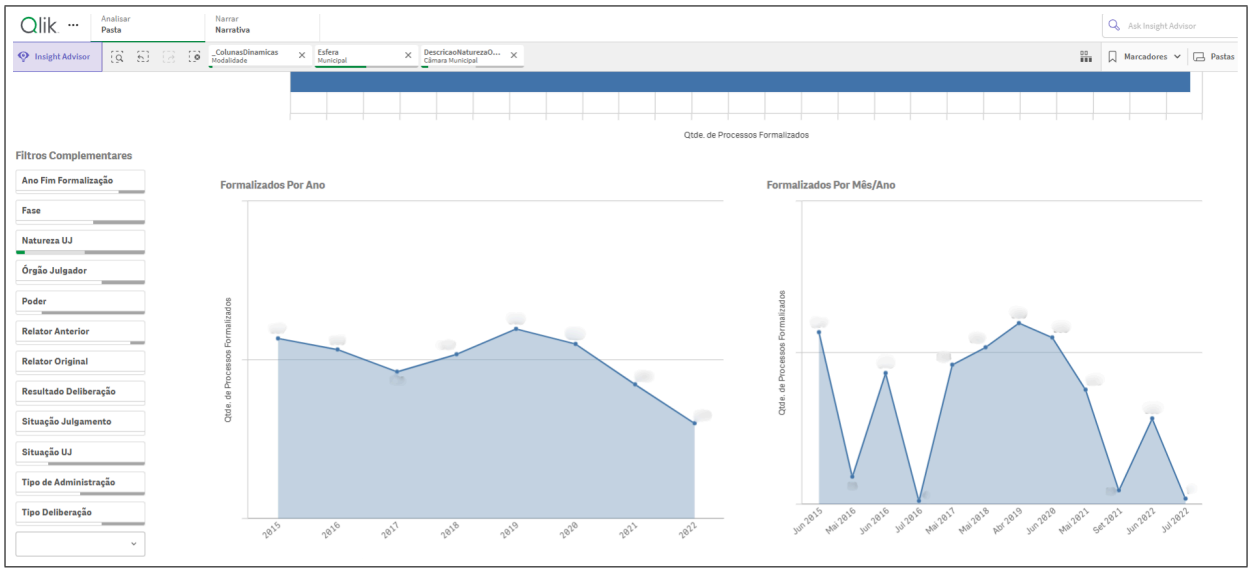

Fig. 8 – Simulation of Formalizations in the Overview Tab, Distributed by Year and Month of Formalization.

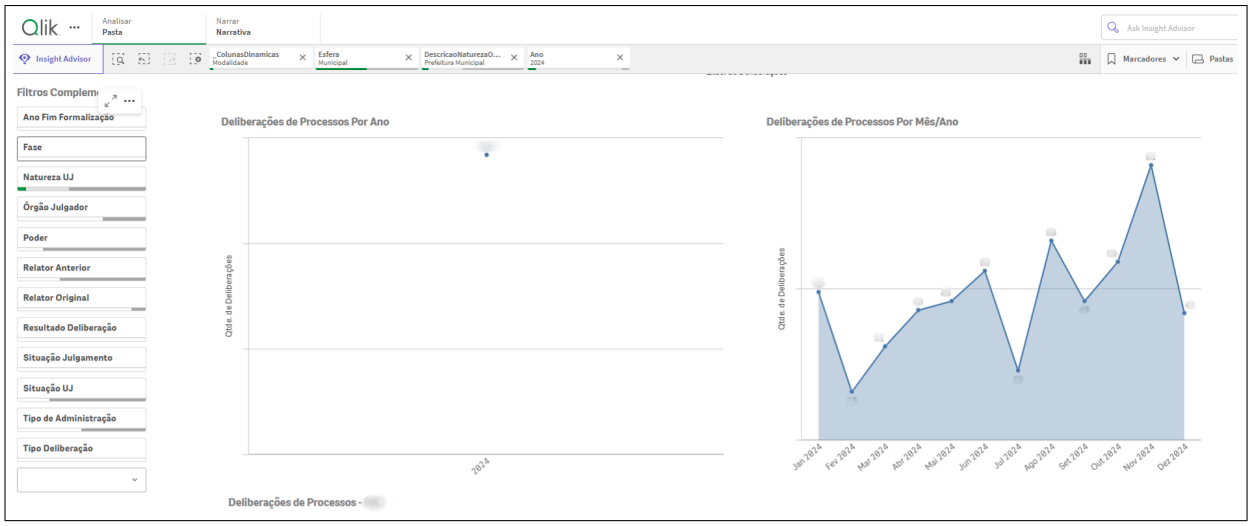

Fig. 9 – Simulation of Deliberations in the Overview Tab, Filtered by Modality and Distributed Throughout 2024.

- **Governance and Accountability:** The dashboard increases transparency in internal processes and strengthens accountability, facilitating the analysis and monitoring of processes by the institution's employees, while ensuring more efficient governance.
- **Scalability and Flexibility:** The developed dashboard has a scalable architecture, allowing flexibility for future adjustments and updates, with the possibility of system expansions as new requirements arise.

Despite the advancements achieved, the new process dashboard at TCE-PE presented some limitations:

- **Limited Implementation Scope:** The dashboard exclusively covers the Accountability modality, one of the main business processes of TCE-PE. However, other procedural modalities could benefit from the dashboard to enhance the analysis and monitoring of their flows. This limitation is due to the prototype having a reduced scope, aiming to ensure agile development and effective implementation.
- **Access and Transparency Restrictions:** The dashboard was designed for internal use at TCE-PE, meeting the needs of the sectors responsible for monitoring and oversight. However, due to the sensitive nature of procedural information, access is restricted to authorized employees, limiting its potential to promote greater public transparency.

- **Absence of Advanced Analytical Features:** The dashboard did not incorporate techniques such as machine learning or predictive models, which could add value to monitoring by estimating deadlines or identifying risks of delays. Artificial intelligence approaches could also detect anomalies and generate automatic alerts for situations requiring managerial attention.

Despite these limitations, the benefits of the developed solution outweighed the challenges, consolidating the dashboard as an essential tool for improving the management and monitoring of processes at TCE-PE. The centralization of data transformations in Qlik Sense mitigated the identified issues, simplifying maintenance and increasing system reliability, ensuring more accurate and trustworthy information. Thus, the developed dashboard was approved by its stakeholders, contributing to greater governance, accountability, and efficiency of the institution.

7. Conclusion and Future Steps

For the public sector, monitoring business processes is essential to ensure good governance, accountability, and transparency. However, maintaining the consistency of the data used is of utmost importance. In this context, this study presented the development of a new BI dashboard for monitoring the Accountability modality processes at TCE-PE, aiming to address the limitations of the previous dashboard, which had usability issues, data inconsistencies, and maintenance difficulties, primarily due to the chaining of multiple views in SQL Server.

The proposed solution centralizes data transformation in the Qlik Sense tool, eliminating the dependency on multiple views and providing greater reliability and efficiency in information analysis. The new dashboard was designed to optimize the analysis and monitoring of processes at TCE-PE, offering an intuitive interface and advanced visualization and filtering functionalities. The segmentation into tabs, the flexibility of dynamic tables, and the diversity of views allow for more precise and efficient tracking of information. With a modular and interactive structure, the tool facilitates data exploration and enables adjustments according to institutional needs. Additionally, its scalable architecture ensures flexibility for future expansions, consolidating the dashboard as an essential resource for strategic management and data-driven decision-making. Furthermore, the new dashboard has also strengthened management by providing more reliable and up-to-date data to support faster and safer strategic decision-making.

In addition to enhancing process management at TCE-PE, the methodology adopted in this work provides a solid foundation for other subnational institutions, including state-level entities in Brazil, to implement similar solutions with minimal adaptation. With appropriate adjustments, the system architecture and approach can be extended to public institutions at various levels, both nationally and internationally, driving the modernization of data monitoring and analysis strategies across diverse governmental contexts.

To ensure the continuous evolution of the new process dashboard, future work is proposed, including the inclusion of new indicators as monitoring analyses are refined. Furthermore, other procedural modalities will be implemented to expand the system's scope and meet additional monitoring and analysis demands. The implementation of more advanced analytical functionalities, such as Machine Learning techniques and predictive analytics, is also envisioned.

Abstract. With the advent of the Knowledge Society, Digital Transformation, and Digital Government, Brazilians have increased their presence and use of digital and knowledge resources to meet their needs. Whether in Government, the Economy, or Citizenship, the digital, knowledge, and innovation era has brought significant challenges and opportunities to Brazil, especially for large Brazilian municipalities. In this context, this study aimed to identify the proposals for Digital Transformation, Technology, and Innovation from candidates in the 46 municipalities with populations exceeding 500,000 inhabitants who were best positioned in the voting intention polls for the 2024 municipal elections. Methodologically, a qualitative study was conducted using the technique of documentary analysis of secondary data, with government plans of the best-positioned candidates in electoral polls from the 46 selected municipalities as the primary source. A nine-step protocol was used to select proposals containing one of the 31 key terms employed. A total of 2,557 proposals from 142 candidates were identified, with 1,268 (49.59%) related to Digital Government, 658 (25.73%) to the Digital Economy, and 631 (24.68%) to Digital Citizenship. With an average of 17 proposals per candidate, the main thematic areas of the proposals were related to Digital Services, Health, Education, Business, and Public Management. The analyzed proposals provide an overview of candidates' priorities and can support the development of public policies that reflect a more strategic perception of the role of digital tools in municipal development, aligned with the demands of an increasingly digital society.

Keywords. Provide Digital Government, Electoral Proposals, Government Plans, Public Policies, Digital Transformation, Digital Society, Digital Economy.

1. Introduction

In recent decades, innovation has gained momentum as a necessary response in public and private organizations driven by the accelerated pace of changes in the political, economic, and social environments (Farias & Porrúa, 2016). These innovations have been facilitating Digital Transformation (DT) in organizations by improving activities, processes, skills, and business models (Demirkan et al., 2016; Piccinini et al., 2015) through Information and Communication Technologies and Information Systems (Takahashi, 2000).

With the growth of DT in everyday life, the use of digital services is growing in the public and private sectors, generating positive and negative impacts on the culture, functioning of organizations, and their employees and users (Vial, 2019). Penmetsa and Bruque-Camara (2021) identified three central elements of a digital nation in the knowledge society: digital society, digital economy, and Digital Government.

From a government perspective, it is understood that in a world of change, governments need to be proactive, considering that new problems require new responses and old challenges require reanalysis (OECD & EUROSTAT, 2018). Thus, innovation in the public sector needs to move from a sporadic activity to a systemic one, where governments can be ready and able to face current and future challenges (OECD, 2018b).

Gil-Garcia et al. (2018) state that information and information technologies have become ubiquitous in the public sector and it is very difficult to think of a public problem or government service that does not involve them in a substantial way. Thus, we can understand Digital Government as the "use of Information and Communication Technologies (ICTs) to provide public services, aiming at greater speed, transparency and citizen engagement" (Layne & Lee, 2001; Le Blanc, 2020; Teo et al., 2008; United Nations, 2020).

According to Weerakkody et al. (2011), a Digital Government can increase efficiency, transparency and offer better public services to citizens and businesses. It will also help to improve public trust in relation to the perception of corruption, increase faster access to government information, reduce administrative costs and increase accountability (Tonggiroh, 2017).

In this sense, the OECD established a set of six dimensions that guide the transition from a traditional/electronic government to a Digital Government: User-centered administration to user-driven administration; From access to information to open by default; From a government as a service provider to a government as a platform for co-creation of public value; From reactive to proactive in the development of public policies and provision of services; Centered on information for a data-driven public sector; From the digitalization of existing processes to digital by design (OECD, 2014).

In Brazil, although the first Digital Transformation Strategy was developed in 2018, it was only in 2021 that the country was able to have its first Digital Government and Public Efficiency Law, Law No. 14,129/2021, known as the Digital Government Law, which establishes principles, rules and instruments for Digital Government and for increasing public efficiency in Brazil (Brasil, 2021).

However, in a country of continental dimensions like Brazil, formed by 27 Federative Units (FUs) and 5,570 municipalities, the implementation of Digital Government strategies is observed in a disproportionate and fragmented manner. The division of power between the federal and subnational governments is established by the Federal Constitution, which defines the exclusive and shared powers of each entity. Thus, each subnational location has its own governments and legislative assemblies (Ávila et al., 2023a).

Therefore, the implementation of policies for a Digital Government does not depend only on federal initiatives, but also on initiatives from subnational governments. A groundbreaking survey helped characterize this Brazilian complexity, in 2023, Ávila et al. (2023b) carried out a broad survey of the proposals of the candidates for Governor of the 27 Brazilian FUs in the 2022 elections, in order to identify in the candidates' government plans, proposals that contemplated perspectives of Digital Transformation, Technology and Innovation. A total of 1,343 proposals from 85 candidates were identified, of which 46% referred to Digital Government, 27% to Digital Economy and 27% directed to Digital Citizenship (Ávila et al., 2023b).

This survey made it possible to identify a favourable agenda especially for the Digital Government theme, directing the positioning of the FUs towards a digital government as a state policy, inserted in the organizational structure of the government, where structural public policies are formulated and decisions on structuring issues of the State are made (Ávila et al., 2023a).

However, when observing the 5,570 Brazilian municipalities, the disparities in access to infrastructure and ICTs are more pronounced, highlighting inequalities between municipalities regarding the adoption of Digital Government, indicating the opportunity to observe at a more basic level how municipal governments position themselves on this issue.

Elections for mayors in Brazil take place every four years and determine the head of the Executive Branch of each municipality. Candidates are chosen through direct elections, in which the winner is the candidate who obtains the absolute majority of valid votes, in accordance with electoral legislation supervised by the Superior Electoral Court (TSE).

The last election for mayors in Brazil took place in October 2024, with 15,574 candidates for mayor. In this scenario, based on the same methodology used in the study conducted by Ávila et al. (2023b), the proposals adhering to the adoption of initiatives focused on digital government in Brazilian municipalities were mapped. Thus, this article aimed **to identify the proposals for Digital Transformation, Technology, and Innovation from mayoral candidates of the 26 state capitals and 20 other municipalities with a population exceeding 500,000 inhabitants, who are best positioned in the voting intention polls for the 2024 elections**.

2. Background

2.1 Science, Technology and Innovation as an Innovation mechanism in the subnational public sector

Science and technology have been increasingly generating value for people through innovative activities. In the digital realm, society has absorbed various innovations into everyday life, such as the adoption of digital applications for banking transactions, purchasing products and services, supporting urban mobility, and even accessing public services (Ávila, Lanza & Valotto, 2023b). Innovations can be understood as the successful exploitation of ideas through the interaction of actors, generating new knowledge and the development of new solutions or the improvement of existing ones (OECD/Eurostat, 2018; Schumpeter & Swedberg, 1942).

In this sense, we observe the rise of Digital Transformation (DT), defined by Demirkan, Spohrer & Welser (2016) as a "profound and accelerated transformation of activities, processes, competencies, and business models to fully leverage the changes and opportunities brought by digital technologies and their impact on society in a strategic and prioritized manner." DT encompasses the deep changes occurring in society, the economy, and governments through the modernization of governance, the management of digital technologies, and, with the growing presence of DT in daily life, the use of digital services increases in both public and private sectors. This generates both positive and negative impacts on culture, organizational functioning, and the experience of employees and users (Vial, 2019).

Within this context, countries worldwide are witnessing one of the most significant transformations in history, as governments and companies have come to heavily depend on the Internet and technology to minimize the disruption caused by lockdowns (Soto-Acosta, 2020).

In a virtuous cycle of how Digital Transformation can support the development of Science, Technology, and Innovation, Ávila, Lanza & Valotto (2023b) highlight advantages such as: increased capacity for data and information processing; improved collaboration and knowledge sharing; facilitation of decision-making; process automation; and access to new data sources.

In the knowledge society, Penmetsa & Bruque-Camara (2021) conducted a study to identify the key elements of a digital nation, composed of three core components: a digital society, a digital economy, and a digital government. These authors point out that nations worldwide are facing challenges in integrating and simplifying their digital infrastructure, identifying six major categories of challenges in literature: people, technology, institutions, policy, economy, and sustainability.

Addressing this issue specifically in the public sector, innovation has been gaining momentum as a necessary response driven by the accelerated pace of changes in political, economic, and social environments (Farias & Porrúa, 2016). However, the OECD (2018) notes that although innovation is present in the daily routine of the public sector, it mostly occurs in a reactive or opportunistic manner rather than strategically. Consequently, government organizations are increasingly falling behind the pace and direction of changes occurring outside the public sector.

Another relevant factor stems from the changes in citizen profiles and attitudes in recent decades. Demographic shifts, higher education levels, greater access to information, and the unlimited capacity to establish connections have combined to create a more informed citizen, more aware of their rights, more participative, and therefore more demanding (Farias & Porrúa, 2016). This new citizen and societal profile generate new and greater demands for public services and policies and stimulates innovation and digital transformation in the public sector (Edler & Georghiou, 2007).

In this regard, public sector innovation must involve the notion of Digital Government, understood as the Digital Transformation of the public sector (Penmetsa & Bruque-Camara, 2021). Since the early 2000s, nations have initiated their digital (or electronic) government policies and strategies, especially driven by the New Public Management movement. According to Weerakkody, El-Haddadeh & Al-Shafi (2011), a Digital Government can increase efficiency, transparency, and deliver better public services to citizens and businesses. It also helps improve public trust by reducing perceptions of corruption, providing faster access to government information, lowering administrative costs, and enhancing accountability (Tonggiroh, 2017).

In this direction, the evolution of Digital Government around the world can be tracked through key international indices such as the “Digital Government Index – DGI” (Ubaldi, González-Zapata & Barbieri, 2020) and the United Nations’ “E-Government Development Index – EGDI” (United Nations, 2020). These indices and related studies compare the development of Digital Government across countries. However, research on this topic at the subnational level remains an area in need of further development.

The difficulty lies in the fact that these indices do not consider the local context of cities within countries, since it

is unlikely that national governments, responsible for the well-being of an entire country, fully understand the needs of communities in the same way that local governments do (Shackleton, Fisher & Dawson, 2004). Therefore, it is important to monitor the progress and shortcomings of innovative Digital Government practices at the subnational level (Edison, Ali & Torkar, 2013), so that medium- and long-term strategies can be developed by policymakers (Taques et al., 2021). For this purpose, it is essential to use appropriate metrics that reflect the stage of development in Digital Transformation and innovation.

3. Methodological Procedures

This is an initial and descriptive study that aims to map and classify municipal electoral proposals related to digital transformation. The analysis provides a general overview of how candidates are addressing digitalization across different dimensions of the knowledge society, laying the groundwork for deeper future investigations. To achieve the proposed objective, a qualitative research study was conducted using the methodology of documentary analysis of secondary data, specifically government plans of mayoral candidates in the 2024 municipal elections in Brazil. Among the 5,570 Brazilian municipalities, this study considered those with a population of at least 500,000 inhabitants, according to the country's official 2022 census, in addition to the 26 state capitals, resulting in 46 municipalities. The methodological protocol was based on nine main steps:

1. Downloading the database of mayoral candidates with registered candidacies on the official platforms of the Superior Electoral Court (TSE) or Regional Electoral Courts (TREs) on August 15, 2024. In the databases, with more than 15,000 registered candidates, the names of the candidates, Federal Units, party numbers, and acronyms were collected.

2. Identifying registered electoral surveys on TSE or TRE platforms to detect candidates representing at least 70% of the voting intentions in stimulated surveys (when candidates' names are announced to respondents) from August 16 to August 20, 2024. This criterion resulted in the selection of the 134 best-positioned candidates in the 46 municipalities eligible for the study. The electoral surveys included in this analysis were collected from 18 distinct institutes: Datafolha, Datatempo, Exata-BR, Futura Inteligência, Futura/100% Cidades, Imape, IPESPE, Methodus, Prefab Future, Quaest, Serpes, Vox Brasil Opinião e Pesquisas, OVALE/ÁGILI Pesquisas, Paraná Pesquisas, Todo Dia/Agili, Radar Inteligência, Real Time Big Data, and Record TV.

3. Downloading the government plans of the 134 best-positioned mayoral candidates in the electoral surveys via the TSE's DivulgaCand platform. When government plans were unavailable or incomplete, they were supplemented through candidates' and parties' platforms or media channels.

4. Updating voting intentions on September 10, 2024, to ensure candidates representing 70% of voting intentions in recent electoral surveys were included, aiming to reflect any changes in candidate standings.

5. Extracting government proposals that included a predetermined set of 31 key terms (in both Portuguese and English), defined by the research team as representative of the digital era: g*overno digital, transformação digital, tecno*, digital, digitaliza*, LGPD, cidade* inteligente*, smart cit*, sistema, aplicativo, app, internet, conectividade, Wi-fi, 5G, portal, website, inclusão digital, central de atendimento, inteligência artificial, machine learning, IA, AI, automa*, laboratório, startup, inova*, transparência, integração de dados, carta* de serviço, dados abertos*. The selection of these terms was informed by a review of relevant literature and public policy documents. Proposals were identified through a systematic keyword search across all documents. To ensure consistency and reduce bias, the coding was first tested in a pilot analysis, and a second researcher reviewed a sample of the results for verification.

6. Reviewing the selected proposals involved assessing their feasibility within the 2025–2028 government cycle. Only those proposals containing action-oriented language—verbs in the infinitive, future present, or present continuous—were retained. Each proposal was manually reviewed and classified according to predefined thematic and dimensional categories. To strengthen analytical reliability, coders followed a shared protocol, and discrepancies were resolved through discussion. This iterative process helped refine the coding categories and ensured alignment with the research objectives.

7. Classifying the proposals into one of three dimensions: Digital Government, Digital Society, or Digital Economy.

8. Classifying the proposals into 23 thematic government areas driven by Digital Transformation, Technology, and Innovation: Agriculture, Control and Accountability, Human Rights, Education, Employability, Sports and Leisure, Public Management, Housing, Inclusion, Infrastructure, Innovation, Artificial Intelligence, Legislation, Mobility, Business, Digital Platform, Health, Public Security, Digital Services, Sustainability, Tourism and Culture, Urbanism,

and Maintenance.

9. Repeating steps 3 to 8 after the first round of municipal elections for seven candidates incorporated from the second round of the 2024 municipal elections, who were not included in the initial delimitations but achieved a sufficient percentage to contest the second round, adding 199 new proposals. all data were condensed into a database available online for consultation (Ávila, Lanza & Valotto, 2024)

This methodological process resulted in 2,557 proposals from 142 candidates. For data analysis, techniques of descriptive statistics and content analysis of the proposals were applied.

4. Results and Analysis

Initially, the 2,557 mapped proposals were categorized among the three dimensions of the knowledge society proposed by Penmetsa and Bruque-Camara (2021), resulting in 2,168 proposals (49.6%) focused on digital government, 658 proposals aimed at the digital economy and 631 proposals linked to digital citizenship. Fig. 1 illustrates the results.

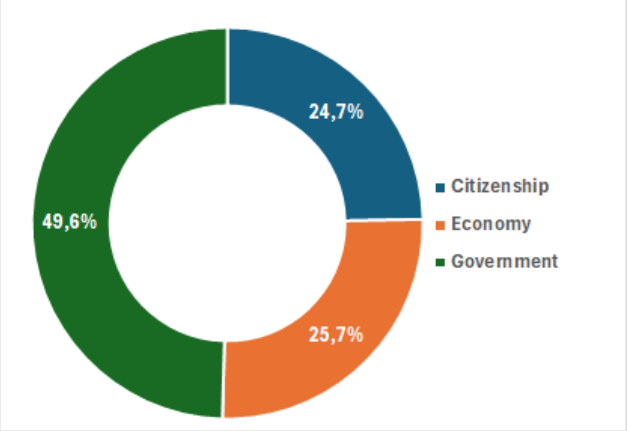

Fig. 1 – Distribution of proposals among the dimensions of the Knowledge Society.

The predominance of proposals focused on digital government indicates that candidates are placing emphasis on modernizing public administration, whether in internal processes or in the provision of public services to citizens. When analyzing the content of these proposals, it is possible to identify that a significant part of them revolve around topics such as digitalization of services, adoption of digital platforms, increased transparency, use or improvement of technological tools, improvement of public management, development of infrastructure, adoption of innovative solutions, among others.

As for the proposals aimed at the digital economy, there is a focus on the modernization and competitiveness of productive sectors through digital technologies. The focus is mainly on the digitalization of businesses through applications, development of technology hubs and parks, tax reductions for innovative businesses, social innovation programs and promotion of entrepreneurship. The main areas highlighted in this segmentation refer to tourism & culture, employability, digital services, innovative businesses such as startups, innovation ecosystems, sustainability and urban planning.

Regarding digital citizenship proposals, the proposals focus mainly on issues such as the implementation of free Wi-Fi access points, digital technological training and qualifications, social and digital inclusion among the elderly, modernization of social assistance, investments in telehealth, training and hiring of teachers, and digitalization of education. Among the priority areas identified in this dimension are mobility, health, education, public safety, infrastructure, and human rights.

The three dimensions were then cross-referenced with the proposals of each of the 46 municipalities included in the study. The distribution is shown in Table 1.

Tab. 1 - Distribution of dimensions by municipality

City	Government Proposals	Economy Proposals	Citizenship Proposals	Total Proposals
Aparecida de Goiânia	19	10	19	48

Aracaju	69	47	33	149
Belém	13	6	4	23
Belo Horizonte	24	14	8	46

Teresina	19	6	9	34

Uberlândia	37	10	15	62
Vitória	13	4	17	34
Total	**1268**	**658**	**631**	**2557**

At least one proposal for this dimension was mapped in all locations. However, since the digital government dimension represents almost 50% of all mapped proposals, this category was also the most frequent among the municipalities, with a variation between 4 and 71 proposals, with an average of 28 proposals per municipality. The five municipalities with the highest number of proposals were: São Gonçalo (71); Aracaju (69); São Paulo (65); Serra (62); and Curitiba (58); On the other hand, the five municipalities with the fewest proposals in this dimension are: Joinville (9); São Luís (7); Boa Vista (6); Juiz de Fora (5); and São José dos Campos (4).

For proposals in the digital economy dimension, we observed a variation between 1 and 47 proposals, with an average of 14 proposals per municipality. The five cities with the most proposals in this category were: Aracaju (47); Palmas (44); São Bernardo do Campo (39); Salvador (36); and Curitiba (29); On the other hand, the six cities with the fewest proposals were: Sorocaba (3); Joinville (3); Boa Vista (2); Juiz de Fora (2); Jaboatão dos Guararapes (1); and Nova Iguaçu (1).

Finally, in the digital citizenship dimension, the proposals varied between 1 and 34, with an average of 14 proposals per city, as well as in the digital economy dimension. The five cities with the most identified proposals were: João Pessoa (34); Aracaju (33); Duque de Caxias (26); Salvador (25); Cuiabá (23); On the other hand, the nine cities with the fewest identified proposals were: Belém (4); Campinas (4); Contagem (4); Florianópolis (4); Jaboatão dos Guararapes (4); Joinville (3); Sorocaba (3); Juiz de Fora (1); São Luís (1).

The next analysis only looked at the number of proposals mapped by city. In this analysis, the ranking of municipalities was established by the total number of proposals and not by the Average Candidate Proposals, since the criterion considered was the greatest possible variety of proposals in a single municipality. Tab. 2 shows the distribution of the 10 municipalities with the largest number of proposals identified.

Tab. 2 – Top 10 municipalities by total proposals

FU	Municipality	Total Proposals	Candidates analysed	Average Candidate Proposals	Rank
SE	Aracaju	149	4	37	1
PR	Curitiba	109	5	22	2
BA	Salvador	107	2	53	3
SP	São Bernardo do Campo	106	4	26	4
RJ	São Gonçalo	101	2	50	5
SP	São Paulo	101	5	20	5
TO	Palmas	97	3	32	7
SP	Osasco	96	3	32	8
MT	Cuiabá	95	3	32	9
ES	Serra	90	3	30	10

The top 10 cities varied between 90 and 149 proposals. In order to deepen the analysis regarding the main themes addressed in these proposals, the frequency of the 23 thematic government areas driven by Digital Transformation, Technology, and Innovation was analyzed, focusing on the top five municipalities with the most mapped proposals.

Aracaju was the municipality with the largest number of identified proposals (149), being the city with the greatest amplitude among the others placed. The main thematic areas of these proposals are “Digital Services”, “Public Management”, “Business”, “Digital Platform” and “Employability”. In second place, Curitiba received 109 coded proposals, mainly on the topics of “Digital Services”, “Employability”, “Business”, “Public Security” and “Digital Platform”. The third municipality with the most mapped proposals was Salvador (107), with a predominance in the areas of “Employability”, “Digital Services”, “Business”, “Digital Platform” and “Education”.

São Bernardo do Campo appears in fourth place with 107 identified proposals, with a predominance of the topics

"Employability", "Business", "Health", "Sustainability" and "Mobility". The fifth place with the largest amount of mapped proposals were the municipalities of São Gonçalo and São Paulo, both with 101 proposals. While in São Gonçalo the predominant themes were "Health", "Business", "Digital Services", "Public Management" and "Mobility", in São Paulo the main themes of the proposals were "Health", "Business", "Digital Services", "Public Management" and "Mobility".

The 23 thematic government areas driven by Digital Transformation, Technology, and Innovation were then analyzed, now considering all 46 municipalities participating in the study, in order to identify the most frequent in each thematic area. The results are presented in Tab. 3.

Tab. 3 – Categorization of proposals into 23 thematic areas

Areas	Proposals	Share	Rank	Top municipality with most proposals in the area
Digital Services	276	10,8%	1	Aracaju (22)
Health	258	10,1%	2	Serra (16)
Education	232	9,1%	3	Duque de Caxias (16)
Business	211	8,3%	4	Palmas (21)
Public Management	209	8,2%	5	Aracaju (18)
Employability	192	7,5%	6	Aracaju (16)
Digital Platform	179	7,0%	7	Aracaju (16)
Mobility	171	6,7%	8	Manaus (11)
Sustainability	164	6,4%	9	Osasco (13)
Infrastructure	158	6,2%	10	Serra (11)
Public Safety	112	4,4%	11	Curitiba (9)
Innovation	92	3,6%	12	Rio de Janeiro; São Bernardo do Campo; São Gonçalo; Uberlândia (6)
Tourism and Culture	66	2,6%	13	Curitiba (8)
Inclusion	53	2,1%	14	Goiania (5)
Control and Accountability	52	2,0%	15	Natal (6)
Legislation	32	1,3%	16	Londrina (7)
Human Rights	31	1,2%	17	São Gonçalo (4)
Artificial Intelligence	25	1,0%	18	Curitiba; Fortaleza; Natal; Salvador; Santo André; São Paulo (2)
Urban Planning	23	0,9%	19	Palmas (3)
Janitorial	9	0,4%	20	Fortaleza; São Bernardo do Campo (2)
Sports and Leisure	6	0,2%	21	Salvador (2)
Agriculture	3	0,1%	22	Rio Branco (2)
Housing	3	0,1%	22	Palmas (2)
Total	**2557**	**100,0%**	**-**	**-**

Among the 23 areas covered, the theme "Digital Services" was the most frequent, with 276 proposals (10.8%). The proposals identified in this area mainly deal with digital management models integrated into online technology platforms or applications, implementation of digital systems in various spheres, use of online scheduling, development or improvement of digital portals for public services, investment in technological infrastructure to increase agility in the use of public services and adoption of virtual service methods. In second place, the theme "Health" was categorized into 258 proposals (10.1%), with proposals focusing on actions such as implementation or advancement in telehealth, Electronic Medical Records, development of an application or website to streamline care, online scheduling of appointments and exams, implementation of electronic panels, interoperability of information between services for appointments and exams, patient history and modernization of diagnostic and treatment equipment in health units.

The theme "Education" was the one with the third largest coding in the study, with 232 proposals (9.1%). The

proposals were mainly directed at modernizing computer lab equipment in schools, digital literacy initiatives, adoption of new information and communication technologies, access to innovative technologies and methodologies for teachers and students, implementation of virtual learning environments, cataloging, digitization and availability of school collections, expanding access to the internet in schools and digital training for teachers.

Regarding the themes with the fewest codifications in the study, we highlight "Agriculture" and "Housing", both with 3 codifications (0.1%). The proposals for "Agriculture" were related to the implementation of a land information portal, the establishment of a municipal agricultural calendar aligned with production chains, and investment in agricultural technology and rural extension with the aim of modernizing the sector. The proposals related to "Housing" were aimed at stimulating innovative projects that expand the supply of housing, the creation of a digital system for monitoring and evaluating housing policies, and the development of new technologies and methodologies that can be applied to housing policies.

Table 2 also allows us to analyze the municipalities with the most proposals in each thematic area. A total of 19 municipalities were identified, distributed across the 23 areas analyzed. Of these, 9 municipalities appear more than once. Aracaju has the highest frequencies in four areas: "Digital Services", "Public Management", "Employability" and "Digital Platform"; Palmas leads in three areas: "Business", "Urban Planning" and "Housing"; Curitiba is ahead in three: "Public Safety", "Inclusion" and "Artificial Intelligence"; Serra is in first place in two areas: "Health" and "Infrastructure"; Natal also appears ahead in two areas: "Control and Accountability" and "Artificial Intelligence"; São Gonçalo leads in two areas: "Innovation" and "Human Rights"; Fortaleza appears with the largest number of proposals in two areas: "Artificial Intelligence" and "Caretaking"; Salvador leads in two areas: "Artificial Intelligence" and "Sports and Leisure"; and São Bernardo do Campo is ahead in two areas: "Innovation" and "Caretaking".

The next analysis sought to focus specifically on the content of the collected proposals, analyzing the 31 key terms used to select the proposals that adhered to the objective of this study. Each proposal could contain more than one key term, thus, 4,626 key term encodings were applied. Fig. 2 presents a word cloud sizing the most recurrent terms in the proposals.

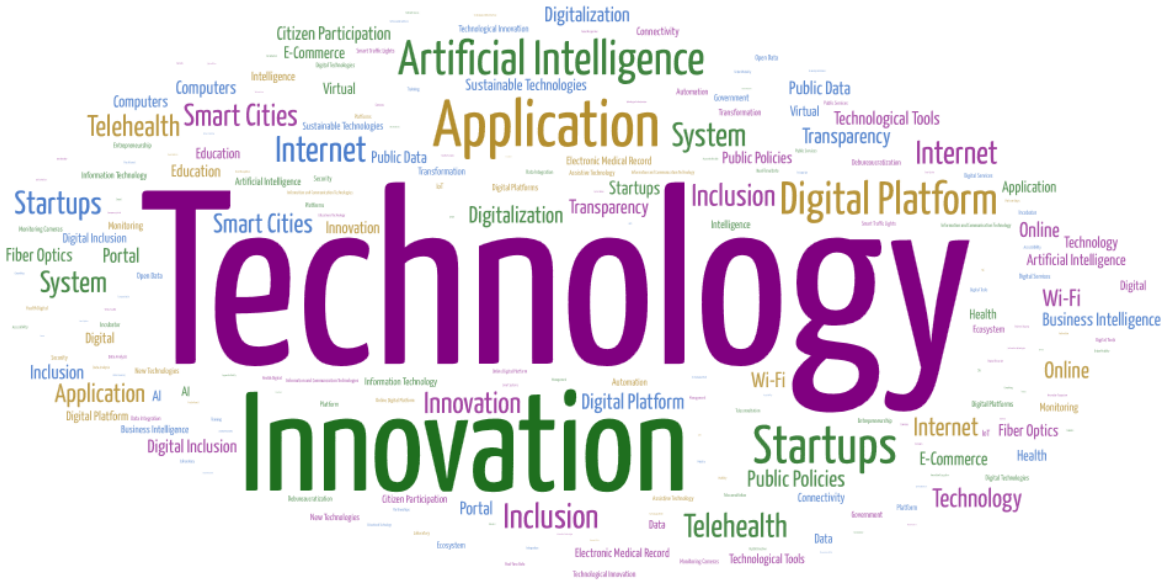

Fig. 2 – Key terms categorized in the proposals.

Fig. 2 shows that the term "Technology" was the most frequent, with 650 mentions. Next, the most recurrent terms were Innovation (371), "App" (175), "Startups" (142), "Artificial Intelligence" (129), "Digital Platform" (122), "Internet" (97), "Inclusion" (93), "System" (89) and "Telehealth" (88). Tab. 4 presents some real proposals that represent each of these terms.

Tab. 4 – Top 10 most frequent terms in proposals and examples

Key term	Original Proposal	Candidate	Municipality
Technology	"Promote the adoption of sustainable construction technologies and practices, with tax incentives for projects that use renewable energy, water	Eduardo Siqueira	Palmas

	reuse and ecological materials."	Campos	
	"Explore new technologies and international best practices to improve the efficiency of security operations and reduce costs, including the use of drones for patrolling and monitoring hard-to-reach areas."	Cristina Graeml	Curitiba
Innovation	"Explore new technologies and international best practices to improve the efficiency of security operations and reduce costs, including the use of drones for patrolling and monitoring hard-to-reach areas"	Anivaldo Luiz da Silva	Maceió
	"Establish, within the scope of the Municipal Executive Branch, the Fortaleza Technological Innovation Fund – FIT, with the objective of fostering technological innovation in the city, encouraging local companies to invest in scientific, technological and innovation research projects, with a view to developing new business models, economically sustainable and with respect for sustainability."	Wagner Sousa Gomes	Fortaleza
App	"Create a digital Labor Office (virtual platform with a mobile App), linked to the City Hall's digital office, to share information about ongoing projects, news about deliberations of the Municipal Labor Council and data on public funds, as well as make job opportunities available in the city to serve the unemployed and those looking for their first job"	Tarcísio Motta	Rio de Janeiro
	"Create an app factory (partnership between IMA and universities) and develop a community delivery platform and app ("iCamp"), which humanizes the work of app delivery drivers and other service providers"	Pedro Tourinho	Campinas
Startups	To facilitate a bank of innovative projects for public management, whether through competitions, qualification of professionals, or by promoting space for technical and academic students to develop their course completion work, aiming at a possible modernization of local public services, as well as being the stimulus for the creation of accelerator/incubator companies – Recruitment of startups.	Emilia Correa	Aracaju
	"Make a Public Center for Creative Economy viable, to attract, develop and disseminate initiatives in this sector with startup business hub incubators."	Marcelo Lima	São Bernardo Do Campo
Artificial Intelligence	"Launch a security application with artificial intelligence to monitor and protect women at risk, including a virtual panic button that facilitates immediate contact with the Municipal Guard."	Leonardo Barreto de Moraes	Porto Velho
	"Real-time monitoring of traffic and road conditions: Use high-definition cameras and artificial intelligence to coordinate rapid action and improve traffic."	Silvio Mendes	Teresina
Digital Platform	"We will modernize public services with the implementation of the E-CG Platform, which will integrate several online services into a single Platform"	Adriane Lopes	Campo Grande
	"Create the digital Platform for Urban Environmental Care, where citizens are registered on the Platform and rewarded through "Osascoin" for tasks within their home space."	Gerson Pessoa	Osasco
Internet	"Consolidate and expand the implementation of free internet access throughout the city (parks, squares, public buildings and public areas)"	Carlito Merss	Joinville
	"Promote free internet to all elementary school students in the municipal public school system to ensure technological education and digital inclusion"	Juliana Brizola	Porto Alegre
Inclusion	"Create Jovem Tech, a technology training program for low-income young people, with Technical Education and Technological Education modalities."	Tabata Amaral	São Paulo
	"Democratize access to technology and promote digital inclusion in the Municipal Public Education Network, using digital tools and resources to improve the quality of education and prepare students for the challenges of the 21st century."	Eder Mauro Cardoso Barra	Belém
System	"Implement Geospatialized System to promote the adequate management of urban space and promote the monitoring of public policies;"	Aline Paranhos Gurgel	Macapá

When analyzing the top 10 key terms, as well as the respective examples of proposals, some intersections of areas can be observed, such as the use of digital technologies and innovations aimed at security (use of drones and artificial intelligence) or for education or inclusion initiatives, such as application development, training programs or provision of free internet.

It is also possible to establish an integration of solutions, such as apps and digital platforms for transparency, integration and digitalization of services. Another relevant aspect is the promotion of innovation and entrepreneurship through startups and innovation ecosystems that encourage technological development and modernization of public services.

Thus, it is clear that the proposals address a complementarity of themes, suggesting for example that digitalization (with terms such as "Digital Platform", "App" and "Internet") can serve as a basis for other innovation initiatives in areas such as education, health, mobility and public safety. It is also observed that the initiatives are not presented in isolation, where technology is seen as a driver for local development.

5. Conclusions

This study aimed to identify the proposals for Digital Transformation, Technology, and Innovation from mayoral candidates of the 26 state capitals and 20 other municipalities with a population exceeding 500,000 inhabitants, who are best positioned in the voting intention polls for the 2024 elections. The results indicated a predominance of proposals aimed at the digital government dimension (almost 50% of the total) at the municipal level, in line with the study by Ávila, Lanza & Valotto (2023b) who, when analyzing the same criteria in the elections of candidates for Governor in the 2022 election, identified 46% of the proposals also aimed at digital government.

This similarity demonstrates a tendency of governors at the subnational level in Brazil to modernize internal processes and the provision of public services through digitalization. The results also indicate a growing attention to digital transformation as a tool to boost the competitiveness of productive sectors and promote social inclusion. The analysis of the 23 thematic areas highlights a more targeted focus on "Digital Services", "Health" and "Education", while the main keywords ("Technology", "Innovation", "App", "Startups" and "Artificial Intelligence") point to the search for solutions that use technology as a basis for initiatives that complement each other, strengthening everything from public safety, education, health, employability, to digital training and innovation in the business sector.

When looking specifically at the municipalities, some cities stand out for the number of proposals and also for the diversity of areas addressed. However, it is important to emphasize that when looking at the proposals broadly, different strategies and priorities are revealed, which vary according to the context and local demands. The sharp economic differences in specific regions of Brazil can present an important barrier that limits the possibilities of innovation and adoption of technologies to advance the digitalization of services and advance digital government equally in the country.

This research has some limitations: (1) The data extraction was conducted from the perspective of the three researchers. A review of the government plans by other researchers might result in a different identification of the set of proposals. (2) Possible changes in candidate standings in electoral polls published after September 10, 2024, were not considered. (3) Some proposals from candidates who were not among the best-positioned may not have been considered. (4) Proposals that did not use any of the key terms adopted in the research were not considered.

Future research could deepen the qualitative analysis of the proposals' content, evaluating their level of innovation, feasibility, and alignment with existing public policies. It would also be relevant to investigate the territorial impact of the proposals, considering regional disparities in access to and priorities for digital transformation. Another

possibility is to analyze the relationship between candidates' profiles and the types of proposals presented, as well as to study how these proposals influence the electorate or are incorporated into government plans after the elections. Future research could also explore more qualitative dimensions of the 5,557 mapped proposals by, for instance, examining their applicability and tracking the implementation efforts of elected candidates. Moreover, subsequent studies may develop indicators to assess the effectiveness of policies in digital government, digital economy, and digital citizenship, thereby enabling a comprehensive evaluation of urban evolution within the context of digital transformation.

Abstract. This paper presents a framework developed by Pernambuco's Strategic Monitoring Data Science Team to design and implement data-driven solutions for monitoring public policies. Using an action research methodology, the study integrates data science, iterative development, and stakeholder engagement. Despite being major producers and consumers of data, governments still face significant challenges in applying data science for policy monitoring, including data quality issues, legal constraints, and institutional silos. Existing frameworks such as CRISP-DM, Scrum, and Kanban are either too technical or primarily focused on software development rather than the policy-driven decision-making required in government settings. The Strategic Monitoring Team was established within Pernambuco's Secretariat of Strategic Projects, comprising a Chief Data Scientist as team leader, a Project Manager, three Data Scientists specializing in modeling, engineering, and visualization, and a Trainee. The team operates through an iterative five-step process: Diagnose, which involves meetings with stakeholders to identify policy issues; Plan, where internal discussions define solutions; Act, which includes the development of dashboards, reports, and applications; Evaluate, to review whether the solutions address policy needs; and learn, focusing on documenting findings and improving tools. To enhance their workflow, the team adapted Scrum methodology by incorporating policy research alongside software development, tracking projects via Notion, and deploying solutions using R and Shiny Proxy. The study highlights that traditional frameworks such as Scrum and CRISP-DM require adaptations to effectively integrate research aspects and government governance structures. By bridging data insights with decision-making processes, the team successfully balances software development, policy research, and institutional needs. The findings emphasize the necessity of specialized data science frameworks tailored for government applications, ensuring a structured yet flexible approach to strategic policy monitoring through data-driven solutions.

Keywords. Government Data Science, Strategic Policy Monitoring, Agile Frameworks for Public Sector.

1. Introduction

This paper aims to report the construction of the framework used by Pernambuco's Strategic Monitoring Data Science Team (SMT) to develop and implement data solutions to monitor strategic public policies. The structure of the paper follows a variation of the proposition in Young and Quinn (2002), with introduction, methodology, results, and conclusion.

The introduction discusses the problem situation and the available alternatives and describes the Pernambuco's Strategic Monitoring Data Science Team. The methodology presents the problem statement, the method and the materials used by the team to create the solution. The results present the framework itself, and the products created by the team. The conclusion summarizes main points into recommendations for those who want no use the framework, discusses limitations and suggests follow-up steps.

1.1 The Problem

First, we must address the question concerning terminology and concepts. Analyzing the question, Saltz and Grady (2017) emphasize the absence of concepts and terms to describe data science and its process, team roles, etc. Aho et al (2021) indicates that there is also a confusion between data science and related concepts (like big data, data science, analytics, machine learning, artificial intelligence, etc.) due to a shared space. Provost and Fawcett (2013) emphasize that these other concepts tend to have a clearer connection with daily practice, resulting, many times, in a confusion between data science and its materials (like big data) or goals (like data-driven decision making).

One good summary of the question is offered by Brady (2019): big data and data science have different meanings but are frequently related to a new volume of data that comes with new methods, new questions, new ethical issues and societal change. Specifically, the author says that Data Science comprehends any process of gathering, representing, preparing, transforming, exploring, modeling, visualizing or presenting data, either using big or small data. Thus, even if big data and data science are different aspects, whit their own elements, the practical use and discussion about any type of data, especially in government, needs to be done along with the debate of data science, since the last governs the use of first to generate value.

Although Data Science is already producing societal changes and increasingly being used as an important tool for business and science (Klievink et al, 2016), according to Nielsen, Persson and Madsen (2019), there are still some barriers to a more complete implementation, which we can classify as technical barriers (like quality, storage and availability) and management barriers (like culture, perception and training).

The government is still starting to utilize data to make better decisions, improve efficiency or better understand social demands to solve public problems. This is a relevant issue, since in the landscape of data, governments are a major player in terms of owning and distributing data, and changes in public sector use of data have the potential to generate even greater impact (Filgueiras and Lui, 2023; Giest, 2017; Nielsen, Persson and Madsen, 2019).

When we think about public sector, all previous barriers also apply and we can add some others like data and information silos (Scott and Gong, 2021), lack of study reports (Nielsen, Persson and Madsen, 2019) and legislation about the use *per si* (Giest, 2017), and more compelling concerns about ethics, fairness and equality, which generates uncertainties and holds back a more complete use (Klievink et al, 2017).

One key element to promote and institute data science as a value approach is the construction of data science teams. Kim et al (2016) states that data scientists are an emerging role on traditional software development teams, but other authors like Aho et al (2021) contribute to show that data science teams multidisciplinary with data scientists coming from different backgrounds, with a recent trend to train data scientists on specific skills.

Both lines agree that, whilst there are some homogeneous aspects like experimentation and iterative development, the practical use of data science presents a large variation in variables like team composition, organization, roles and size; position in organization (internal / external); management framework and process; use of big or small data; project scope (from simply organizing data to advanced uses of machine learning).

Another common ground is that education and lack of definition about roles in data science teams are a key component. Saltz and Grady (2017) argue that in this context the formation of a data science team is still an issue, since it is difficult not only to train people, but to attribute team roles and to create team framework. Considering

the Brazilian case, De Toni and Dorneles (2022) say that the efforts to train public servants on data science is still recent and that there is a large variability on the use. Kim et al (2016) reinforces that, in many situations, unlike traditional development teams, Data Science teams focus more on skills than on roles and static attributions.

However, another relevant point, however, is that, even with different backgrounds and skill sets on Data Science Teams, the available frameworks are still focused or emerge from software engineering backgrounds, resulting on a lack of orientations regarding other Data Science tasks, such as research and study reports.

This scenario of low definition, high variability, and few specific studies on government data science teams leads to a problem-situation in which government data science teams need to create their own framework, comprehending team roles, scope of projects and development process, expanding the available ones to include missing parts, like research and study reports.

1.2 Alternatives

Saltz and Grady (2017) produced an interesting cross section study about different cases of frameworks for data science team organization, skills and roles, compared with the types of data scientists job positions on dice.com. The findings showed that the main roles are researcher, scientist, architect, analyst, programmer and engineer.

Expanding the first study, Saltz and Hotz (2020) conducted a new survey-based study, this time focused on projects frameworks. They found out that CRISP-DM was still the most used, reaching 49% of the respondents, followed by scrum (18%), kanban (12%), TDSP (4%) and SEMMA (1%). Customized frameworks (12%), others (3%) and none (2%) were also mentioned.

Resuming the two studies, we may say that: (i) available project frameworks focus more on methods / steps (CRISP-DM, TDSP, SEMMA) or governance / coordination (Scrum, Agile, Kanban) (i) the main framework, CRISP-DM was built in the late 1990s, before some of the actual technologies were even available; and (iii) of the organization frameworks only EDISON focused on researches data scientists.

Considering that available frameworks (i) comprehend only the methods or the management, (ii) are not suited for government, (iii) don't address the role of research on data science projects and teams, and that (iv) is common that data science teams feel the need to develop their own frameworks because of the range of skills, tasks and data need to develop their projects, after the research for alternatives, we reinforced our belief on needing to develop our own framework.

1.3 Problem Statement

The problem statement was done using the How Might We? – HWE (Brown, 2020) to produce a statement capable of solving and opened enough to allow innovative solutions: How might we create a data science framework comprehending team roles, scope of projects and development process, to increase the efficiency of data projects for strategic monitoring?

1.4 The Strategic Monitoring Team

The Strategic Monitoring is a Data Science Team focused on creating data solutions to extract value from data, In Pernambuco State (a Brazilian subnational government), the team is a Sub-secretariat of the State Secretariat of Strategic Projects, responsible for the implementation and monitoring of strategic public investments.

The team is composed of five public servants and one trainee, who gives support for different activities. Three members are data scientists that divide the tasks according to project thematic; one member is the project manager; and the other is the chief data scientist, also occupying the position of sub-secretary of strategic monitoring. Except for the project manager, who has a strong background in business and government, the members have strong academic backgrounds, with three PhDs.

Different tasks are performed according to specific project needs, but the main are data engineering and wrangling, exploratory data analysis, data modeling to predict and classify, DataViz, optimization to create prescription alternatives, construction of study reports, dashboards and presentations. In some cases, the team also develops data input software.

The team uses R as its main technology. R is used to tasks from data engineering to data modelling, and to create the templates used to develop apps with shiny framework, and study reports in .pdf or .html or presentations using reveal.js through quarto framework. The deploy is done using shiny proxy, which offers better load balance, routing and access control.

It is important no say that, since the team is responsible for strategic monitoring, the portfolio construction and project selection criteria is mainly top-down. The team receives demands from the secretary of strategic projects, the secretary of mobility and infrastructure or directly from the center of government.

The figure resumes the team's organization and tasks.

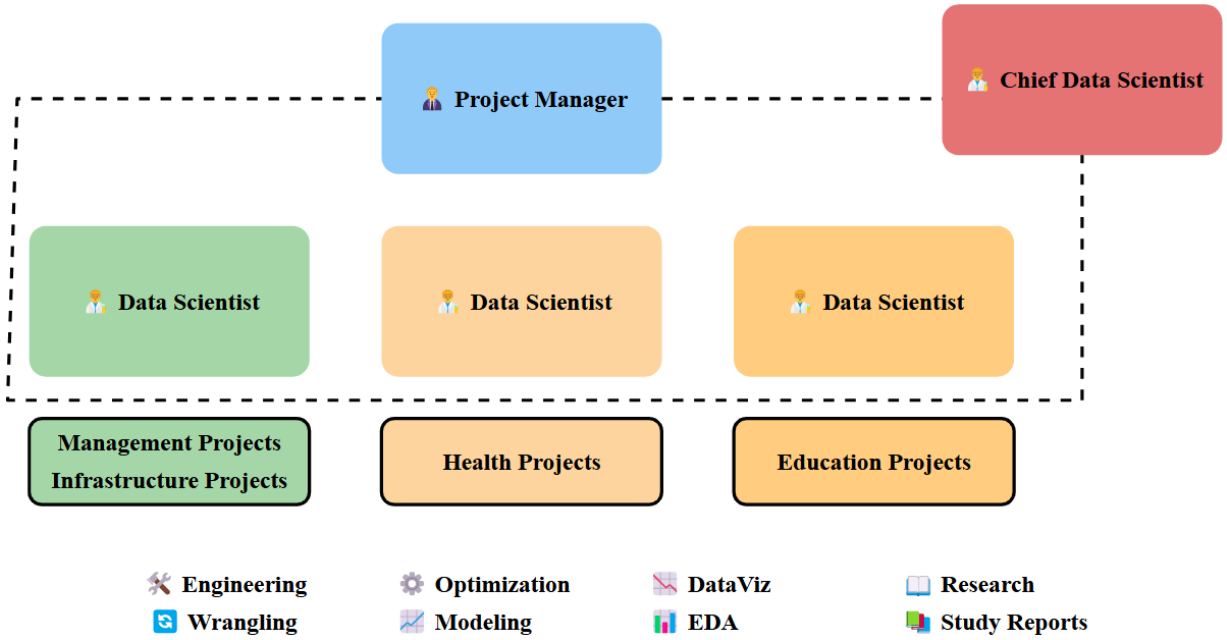

Fig 1 – Strategic Monitoring Team.

2. Methodology

2.1 Method

The Strategic Monitoring Team framework was created considering the literature of alternatives to manage data science team, the analysis of the team's empirical practice and the elements (artifacts, ceremonies and products) of scrum (Schwaber and Sutherland, 2020), using action research methodology as the conductor. The results are the framework design and details, a table comparing the artifacts, ceremonies and products of scrum with those used by the team, and a summary of the data products build so far. The discussion resumes the alternatives limitations to government data science teams and the learned lessons from the Strategic Monitoring Team.

For example, during the development of one of the products, the app Hortensias, it was always important to focus on problem-solving and practitioners' involvement, but also to document the innovation process and the software development. So, the leading methodology used was action research, which can be defined as a cycle process of diagnosis, plan, act, evaluate and document to improve practice or solve a problem, combining acting and inquiring about it (Tripp, 2005).

As argument by Ollila and Yström (2020), action research is an important method to conduct innovations because it is more capable to get practitioners involved, which tends to approximate solutions and problems, while generating richer insights and more significant knowledge.

Some authors as Saarikallio and Tyrväinen (2022) and Natarajan and Pichai (2024) have achieved success on utilizing action research to inquire about agile software development process, since the cycle nature of agile has an adequate fit to also cycle perspective of action research. But Action Research can offer contributions to Data Science Teams because it has a more robust approach to dealing with the research aspects of Data Science tasks.

Regarding data science specific techniques, the data engineering process uses the extract, transform and load – ETL framework (Kimball, and Ross, 2013), storing the final data with proper dimensions and metrics in a corporate GreenPlum distribution; the monitoring process uses exploratory analysis statistics and data visualization such as time series, key performance indicators, and data summaries (Tukey, 1980; Wickham, and Wickham, 2016; Staniak, and Biecek, 2019). Finally, in some cases the team uses machine learning and optimization techniques.

Thus, our methodology uses action research to review team roles, artifacts and ceremonies, considering integrating

research.

2.2 Materials

The team uses materials to perform its action research cycle the notion platform with a custom workspace, divided in:

- **Projects**. Page with data and information linked to current projects, including backlog, reunions, project chartet, etc.
- **Reunions**. Page with data and information linked to reunions, with focus on calendar, tasks and follow-up taks.
- **Notes**. Page with annotation and miscelania information that is note directly linked to any of the other pages.
- **Cerimonies**. Page with description of the cerimonies adopted by the team.
- **Databases**. Page with the databases used on other pages.

Other relevant material is the team landpage, called box (https://box.pe.gov.br/), in honor of George E. P. Box. The landpage concentrates the products developed by the team, offering a summary, a point of access and the link to the team repository on github, which has the codes and proof of concepts (POC) of all products.

3. Results

3.1 Action Research Cycle

Following literature indications, we created our own action research cycle, adapted to our DS team routines. But, before the cycle enters operation, it is necessary that a project be presented by the secretary or prospected by the team, and the project charter being written in general lines.

- **Step 1 – Diagnose**. Meetings with practitioners that live and understand the problem context, the pain points and the reasons why their occurs. The meetings were translated into high level requirements and follow-up tasks using notion. After the meeting, the team also concudcts research tasks (simple literature revision and bechmarking) to get a more general understand of the problem and to prospect what are the possible solutions or best practices. The meetings usualy take 2h to 3h, and is scheduled by the team's project manager.
- **Step 2 – Plan**. Meetings with the DS team to define discuss research findings, to define products design and features, to estimate time and to build the backlog. Notion is used to register and monitor tasks.
- **Step 3 – Act**. Hands-on, effectively developing the products based on the diagnoses and the research findings. The development is done using the templates available on the team package called vialactea. At this moment, the data scientist have individual daily meetings with the chief data scientist and the project manager.
- **Step 4 – Evalute**. Meetings with the same practitioners in step 1 with the goal to evaluate if the producuts solve the pain points. This steps gets a little confused with step 1, in the sense that practitioners tend to address new pain points continuasly as the previsou are solved. Once the project is deployed and delivered, it enters on a continuous process of strategic monitoring, being used in decision-making. At this point, the evauation is incorpored in monitoring reunions.
- **Step 5 – Learn**. Document the findings and lessons during the DS team meetings. Github repo is updated and the main lessons go to the R package vialactea to become default features in further projects and to be back implemented in previous solutions. Also, the products are deployed and their information is made available in the team landapge. This is a team moment, lead by the chief data scientist and the project manager.

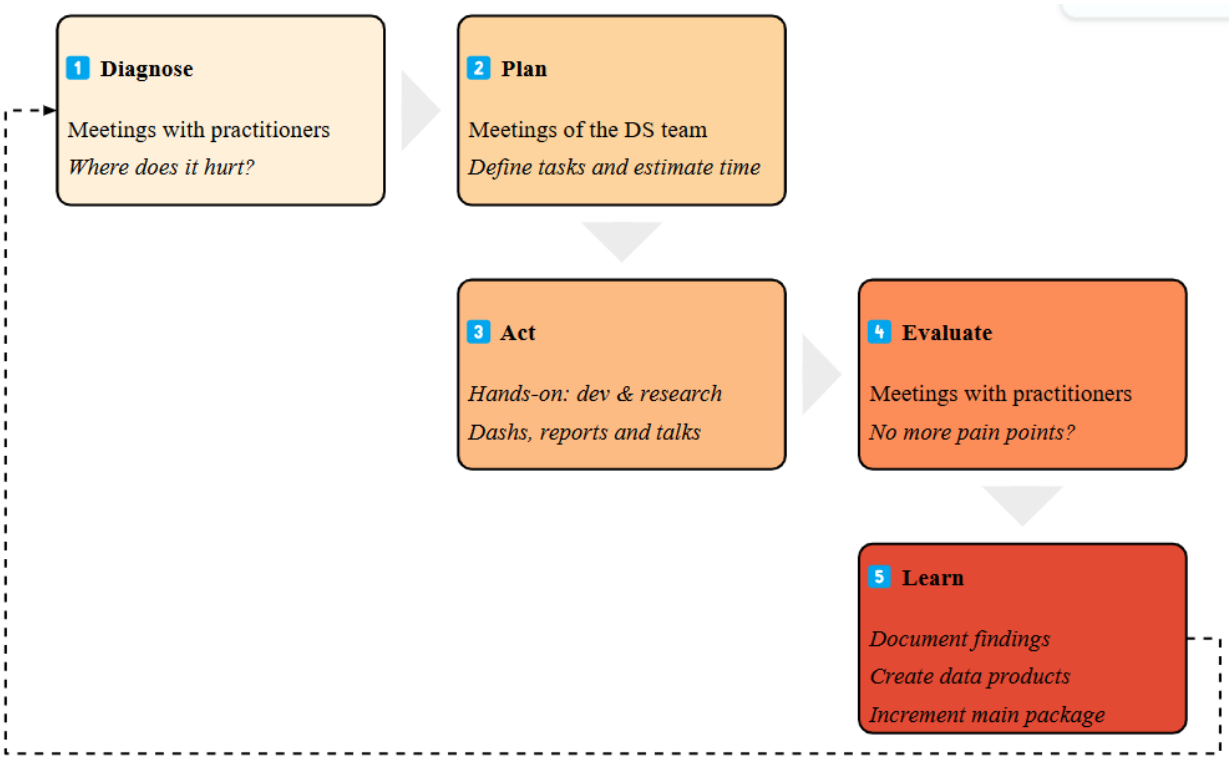

Fig 2 – Summary of the DS Team Action Research Cycle.

3.2 Artifacts, ceremonies and roles

Project management is done using a variation of scrum, in which the project manager acts as scrum master, and the data scientists act like product owners and development team. As POs, data scientists are responsible for interactions with demandant practitioners and business teams, and also for performing academic research to better perform data tasks. The chief data scientist deals with administrative demands but also as leader developer, being responsible for establishing the software developing standards, study report guides and research methods.

Thinking about the artifacts and the ceremonies, we may say that product backlog and sprint backlog are used, as also product increment. These artifacts are adapted to be used not only for software products, but also for research products, resulting, in this case in shorter backlogs with topics to be explored. The team has a weekly sprint, with planning and revision meetings occurring on the same day. Retrospective meetings are done once per month for software, and, for research, when the first summary of findings is done and when the presentation and report are done.

The following table compares scrum elements and the ones used by the team, detaching with * those that do not exist on Scrum.

Tab. 1 – Comparison of artifacts, ceremonies and roles on scrum and on Strategic Monitoring Team.

ELEMENT TYPE	SCRUM	STRATEGIC MONITORING TEAM
ARTIFACT	Product Backlog, Sprint Backlog, Product Increment	Used in software and research products
CEREMONIES	Backlog Refinement, Planning and Revision	Weekly in the same day
CEREMONIES	Daily	The same
CEREMONIES	Retrospective	Once per month
ROLE	Scrum Master	Project Manager
ROLE	Product Owner	Data Scientist
ROLE	Team member	Data Scientist and Chief Data

		Scientist
ROLE	Administration*	Chief Data Scientist

3.3 Products

The team products are divided into two main different axes: software products (apps, chatbot and packages) and research products (presentations and study reports).

Apps. Data Science Softwares that offer dynamic dashboards to interacte with data and automate analytics tasks like prediction and optimization. The apps have acces control and collect usage statistics. Some exemples are: (i) *Amparo*, an app to monitor highways construnction, focused on data engineering of 4 different data silos and dataviz; and (ii) *Hortensias*, an app to monitor public spendings, that also has a heavy use of data engineering and dataviz, but also focus on more complex tasks such as spending predictions and budget optimization.

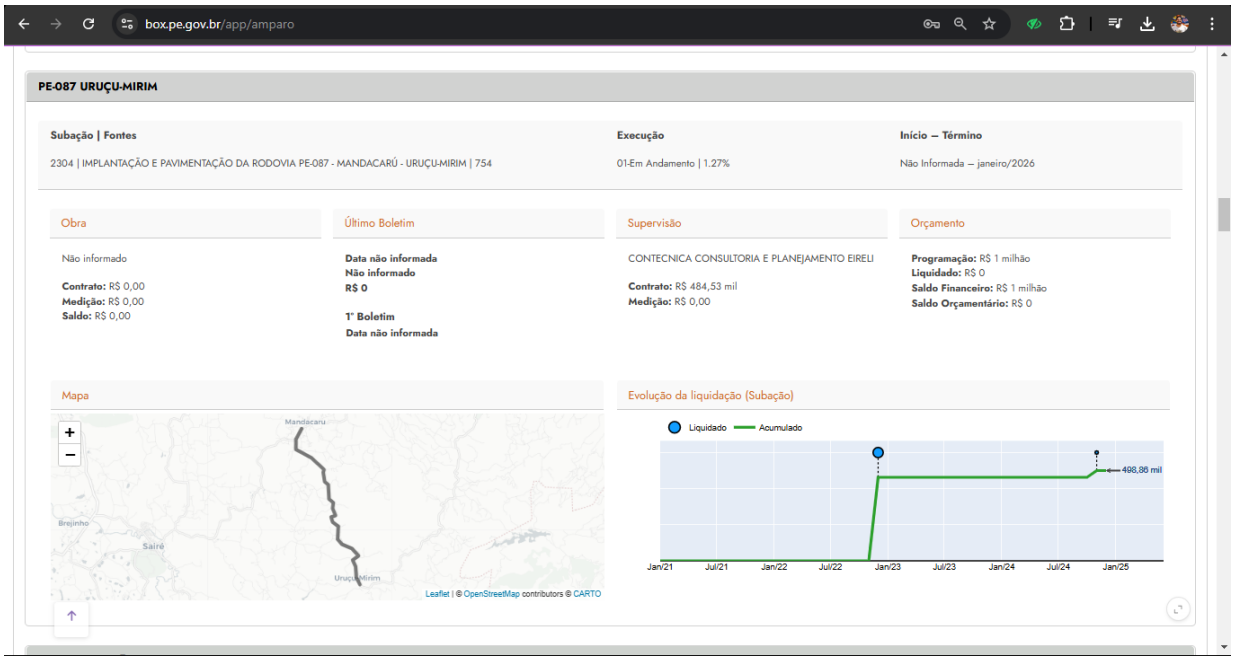

Fig 3 – Amparo App.

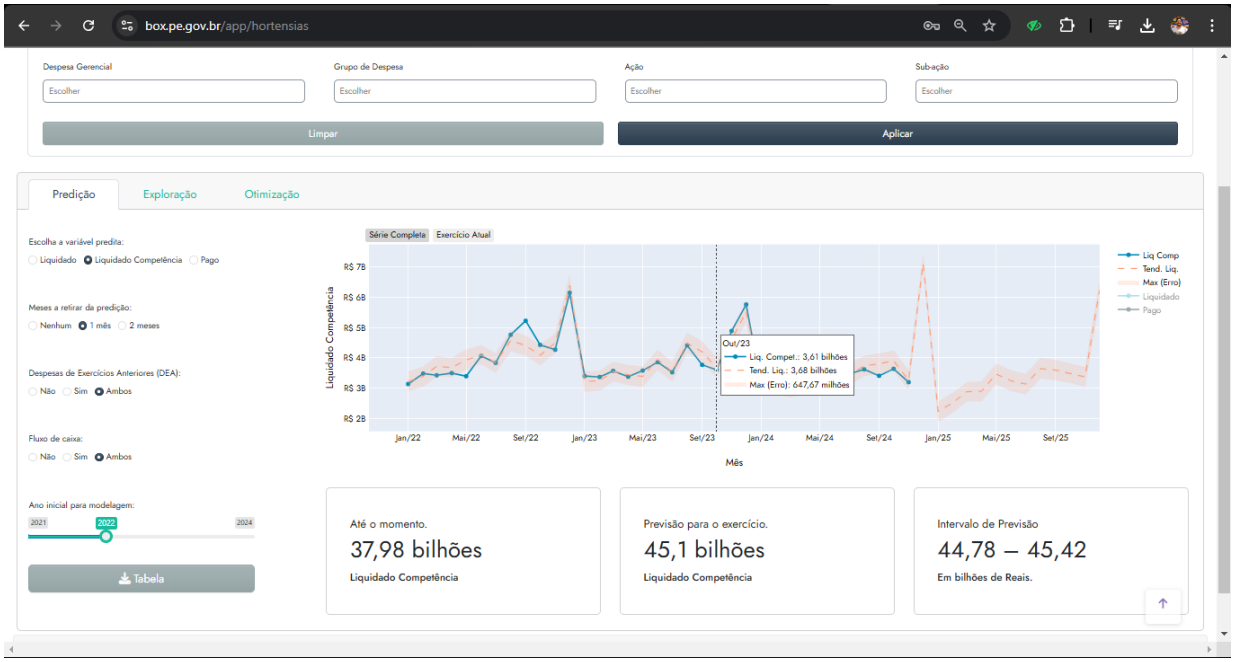

Fig 4 – Hortensia App.

Argos. Argos is our WhatsApp chatbot that offers just in time information to strategic users via text messages. Currently, Argos is capable of reading most of the databases used on apps and has commands to summarize and present data in text format.

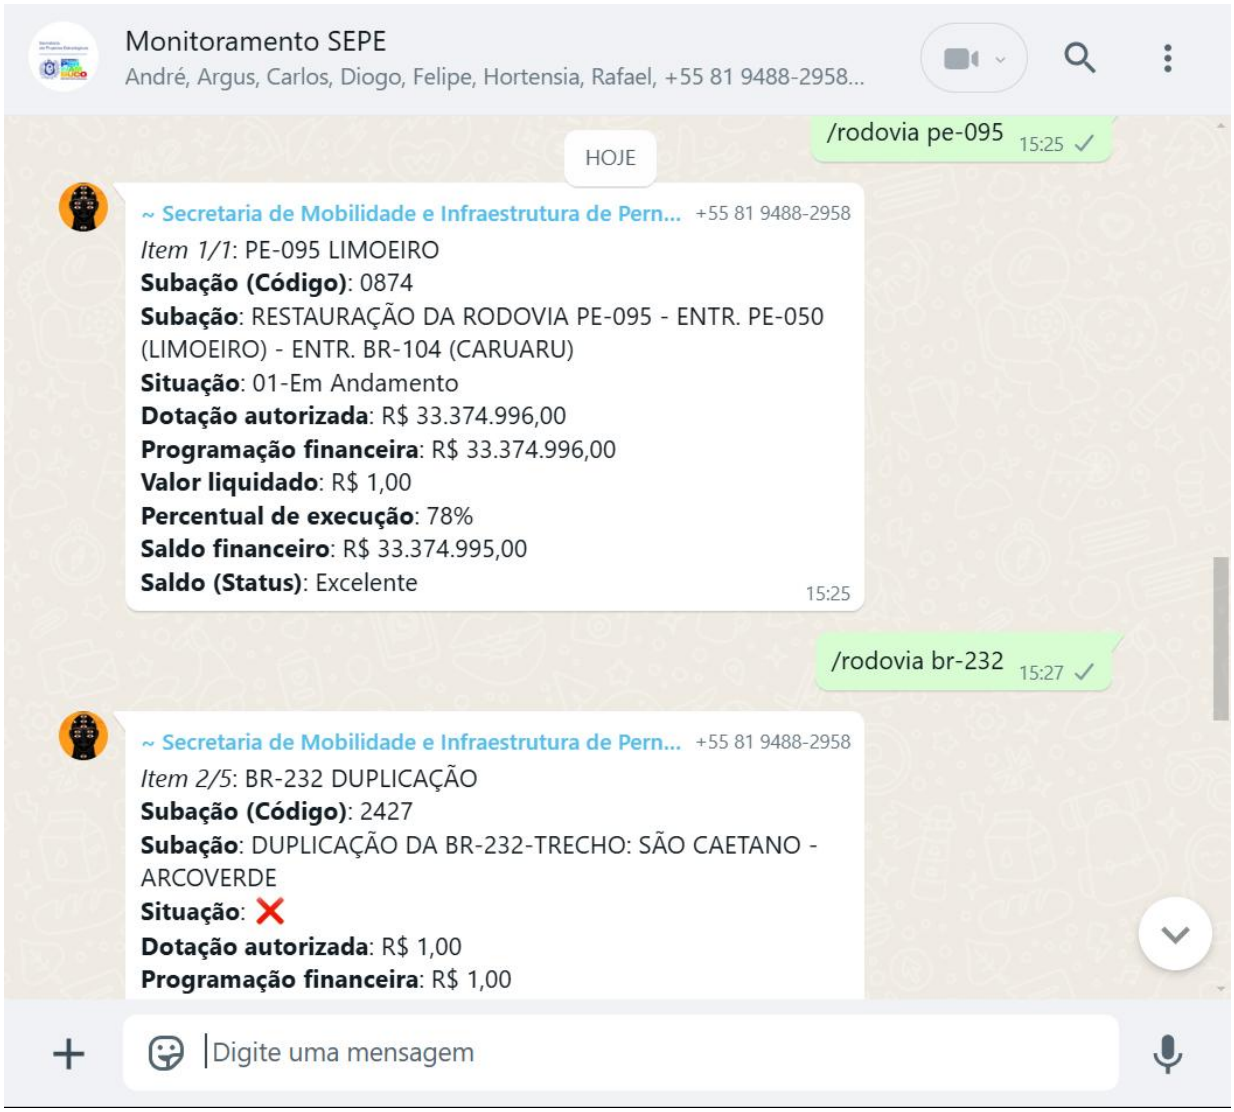

Fig 5 – Argos chatbot.

Packages. When the data science team creates solutions that may be used in other contexts, they are delivered in the form of a R package. The example is the BigDataPE an R package that provides a secure and intuitive way to access datasets from the BigDataPE platform.

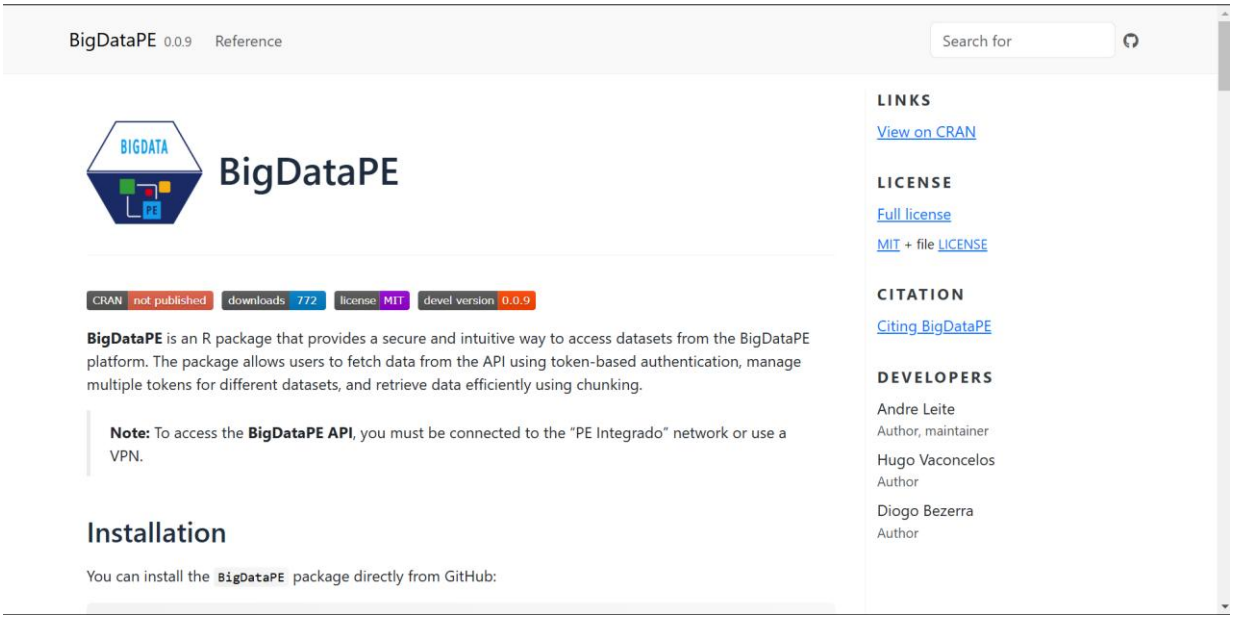

Fig 6 – Maternity study report.

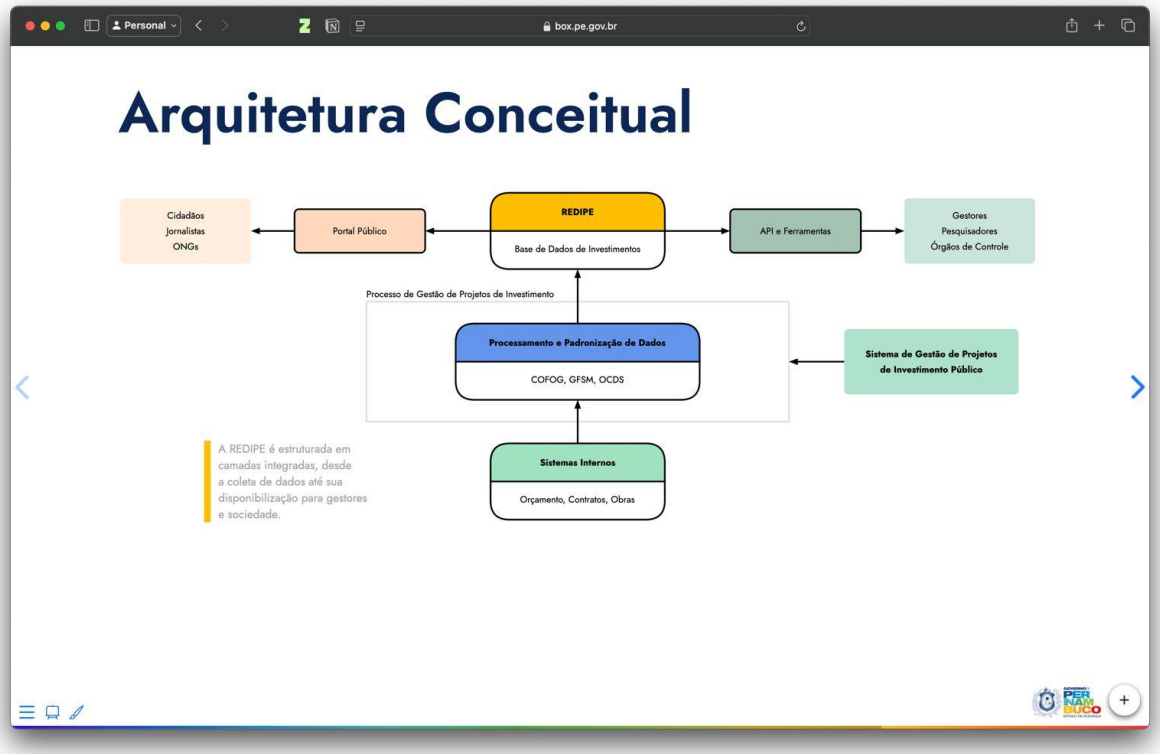
Presentations. Data Science presentations based on research and data analysis. Less dynamic but with defined storytelling. One example is REDIPE presentation, which focuses on present the research and benchmarking of alternatives to manager data of public investments.



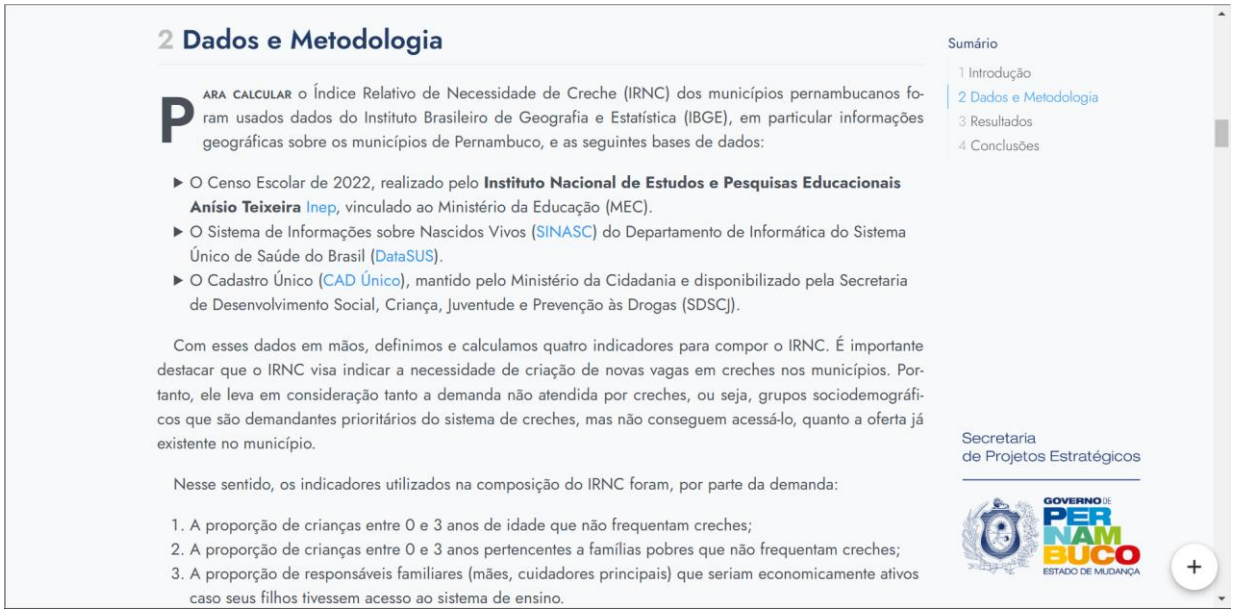


Fig 7 – REDIPE presentation.

Study Reports. Data science study reports based on research and data analysis. Less dynamic and with defined storytelling like the presentations. The description is denser and aimed at detailing all research aspects and data analysis. An example is maternity location analysis, which focuses on present the research and data analysis of early childhood education.

2 Dados e Metodologia

Para calcular o Índice Relativo de Necessidade de Creche (IRNC) dos municípios pernambucanos foram usados dados do Instituto Brasileiro de Geografia e Estatística (IBGE), em particular informações geográficas sobre os municípios de Pernambuco, e as seguintes bases de dados:

- O Censo Escolar de 2022, realizado pelo **Instituto Nacional de Estudos e Pesquisas Educacionais Anísio Teixeira** Inep, vinculado ao Ministério da Educação (MEC).
- O Sistema de Informações sobre Nascidos Vivos (SINASC) do Departamento de Informática do Sistema Único de Saúde do Brasil (DataSUS).
- O Cadastro Único (CAD Único), mantido pelo Ministério da Cidadania e disponibilizado pela Secretaria de Desenvolvimento Social, Criança, Juventude e Prevenção às Drogas (SDSCJ).

Com esses dados em mãos, definimos e calculamos quatro indicadores para compor o IRNC. É importante destacar que o IRNC visa indicar a necessidade de criação de novas vagas em creches nos municípios. Portanto, ele leva em consideração tanto a demanda não atendida por creches, ou seja, grupos sociodemográficos que são demandantes prioritários do sistema de creches, mas não conseguem acessá-lo, quanto a oferta já existente no município.

Nesse sentido, os indicadores utilizados na composição do IRNC foram, por parte da demanda:

1. A proporção de crianças entre 0 e 3 anos de idade que não frequentam creches;
2. A proporção de crianças entre 0 e 3 anos pertencentes a famílias pobres que não frequentam creches;
3. A proporção de responsáveis familiares (mães, cuidadores principais) que seriam economicamente ativos caso seus filhos tivessem acesso ao sistema de ensino.

4. Conclusion

The first point to address is that, as highlighted in the literature about data science teams, data science is a broad and complex field, deeply connected to other disciplines in science, technology, and innovation. During our research, we found no specific frameworks that fully aligned with our team's primary goal: creating data-driven monitoring solutions. Existing frameworks were either too generic—such as Scrum and Kanban—or too focused on technical data science workflows, often neglecting the research phase and the structured development of necessary products. This gap led us to develop our own tailored framework.

Action research proved to be a highly effective methodological approach for customizing our artifacts, ceremonies, and roles, as it integrates both the research and iterative development aspects of data science, providing structured guidance for inquiry and reflection on practice. This dual focus allows for continuous adaptation and improvement, making it particularly well-suited for governmental contexts, where rigid bureaucratic structures often clash with the need for flexibility and responsiveness.

One relevant limitation of such approaches as action research is the selection and confirmation bias, because the researches are very close to the problems they are investigating. Thus, adaptations of the framework must consider this limitation, and procced an adaptation to the context of each organization, since aspects like regulation, time size, governance, and number and resistance of data-silos vary from institution to institution.

Also, the adaptations of traditional agile framework are necessary due to public sector constraints, like a more rigid organizational structure, strong hierarchization and segmentation of activities, as well as severe restrictions regarding resource availability and staff training. One of the most challenging points is to balance the roles, since in original Scrum framework the Scrum Master and the Product Owner have framed activities and responsibilities, which need to be done by the development team. For this to work, it was very important to have a senior team, and to focus every data scientist on a theme portfolio. Nevertheless, those aspects have been experienced in other similar implementations in Brazil, as documented by different authors, like Vacari (2015), Rosa and Pereira (2021), and Guimarães et al (2025).

All things considered, and beyond the specific needs of our team, we believe that our framework addresses fundamental challenges faced by government data science teams. These include the difficulty of coordinating traditional hierarchical structures with matrix management approaches, as well as the broader struggle to balance agility with institutional requirements. Our framework offers a foundation upon which public sector organizations can customize agile elements while ensuring alignment with governance protocols.

When considering the public sector, additional challenges further complicate the implementation of data-driven approaches. Issues such as data and information silos, the scarcity of comprehensive study reports, and legal constraints regarding data usage create structural barriers to effective data science initiatives. Furthermore, ethical concerns related to fairness, transparency, and equality add layers of complexity, fostering uncertainties that can hinder the full adoption of data-driven methodologies. Addressing these barriers will require not only

technical solutions but also institutional and regulatory adaptations to create an environment where data science can thrive in the public sector.

At the moment we don't have a method to evaluate impact of the solutions regarding efficiency, efficacy, influence in decision-making or comprehension about social problems. Nevertheless, we understand that this is a general limitation of evaluating the impact of monitoring and business intelligence solutions.

As a continuous agenda, with more products being created, we aim to develop mechanisms for systematically collecting organic and structured feedback, ensuring a deeper understanding of user needs and experiences. Another pending issue is the transformation of our landing page into a more informative and user-friendly platform, enhancing transparency and accessibility. Finally, we recognize the need for a sustainable workflow for technological retrofitting, enabling the incorporation of lessons learned from previous projects into future iterations. These steps will contribute to the long-term sustainability and effectiveness of our data-driven monitoring solutions in the public sector.

Abstract. This research explores how distinct municipal contexts in Brazil influence the design and implementation of digital public policies, focusing on two city-level digital initiatives. The study investigates the paradox of digital government efforts, which aim to enhance inclusivity and efficiency but often exacerbate the digital divide, particularly affecting underprivileged populations. This issue is significant for public administration, as understanding how local contexts shape policy outcomes is essential for creating inclusive and effective public services. Existing frameworks can fall short in addressing this puzzle because they often neglect the role of contextual variability and the necessary local adaptations to overcome digital exclusion. These frameworks overlook how sociotechnical factors specific to each locality impact user engagement and the success of digital policies. Building on this gap, we hypothesize that the adaptability of municipal governments to local demands and digital barriers is a decisive factor in user adherence and policy effectiveness. To address this question, we conducted a comparative analysis of two municipal digital initiatives: the "Ouvindo Nosso Bairro" participatory program in Salvador and the "Saúde Já Curitiba" digital health platform in Curitiba. These cases demonstrate how municipal governments have tackled digital barriers and tailored information and communication technology (ICT) solutions to meet the diverse needs of their populations. Our qualitative research design combines documentary analysis with interviews of program managers and participants. Fieldwork and primary data collection took place between October 2022 and January 2023. Using the digital divide lens, we analyze how local contexts influenced the development and outcomes of these initiatives. This study aims to contribute to the broader discourse on digital inclusivity by demonstrating how municipal governments can adapt public policies to bridge the digital divide. By offering insights into these adaptations, the research aligns with the Sustainable Development Goals, particularly those promoting inclusive and equitable societies, reducing inequalities, and fostering innovation in public administration.

Keywords. Digitalization, e-government, ICT, Digital Divide.
Research paper, DOI: https://doi.org/10.59490/dgo.2025.962

1. Introduction

Following the global trend of government service digitization (Alston, 2018), Brazil has been implementing e-government initiatives at various levels of government and across different areas of social welfare. These initiatives are justified by claims that digital solutions promote greater efficiency, improved service delivery, transparency, and fraud prevention, among other benefits. However, these approaches transfer the responsibility to citizens, requiring them to independently access and manage social services through information and communication technologies (ICT) (Schou & Hjelholt, 2019).

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

At the same time, especially in developing countries, digital exclusion remains a persistent reality that reinforces existing social inequalities. In Brazil, according to data from CGI.br. (2024), approximately 84% of the population aged 10 or older accesses the internet, meaning that more than 34 million (16%) Brazilians still do not use it. Among internet users, 73% used e-government services. With the urgent need to reduce poverty and inequality in the current decade and the growing body of literature on the subject, it is possible to observe that these two contexts - the digitization of public services and digital exclusion - seemingly contradictory, demonstrate the need to fully understand the consequences of digital welfare, particularly for the disadvantaged, poor, and digitally excluded, who tend to be those who need the benefits that public policies can bring the most. Therefore, to create public services that fully meet the needs of users, it is crucial to map and understand the current state of the provision of these services, including interactions, information flows, and data among public sector organizations and the public's experience (Welby & Tan, 2022).

This research addresses the adaptability of digital public policies based on their context, recognizing the multiple factors that cause digital exclusion of the local population. The main question that guided this research is "How can digital public policies be designed to maximize citizen engagement and ensure equitable access to services, while addressing the digital divide and adapting to local socioeconomic and technological contexts?", followed by two secondary questions "How can municipal governments design digital services that effectively address the diverse needs of digitally excluded populations?" and "What are possible municipal goverment mechanisms for alleviating the digital divide and improving engagement in digtial policies?". To answer these research questions, this article presents two case studies of the digitalization of municipal policies to understand how ICTs can be adapted in the public sector, especially considering technologies accessible to citizens from different backgrounds. Furthermore, we believe this research can assist researchers and policymakers in crafting more digitally inclusive public policies, as both cases studied showed the ability to adapt to make them accessible to a wider range of users.

Our research aligns with the context of research on digital exclusion, which considers sociodemographic variables to have a significant impact on public policy discussions. Neglecting power structures, norms and social structures, culture, and access to resources can deepen the inequalities already experienced by vulnerable citizens, further hindering their individual, social, and economic development. Thus, it also aligns with some of the United Nations' Sustainable Development Goals (SDGs), "the current conceptualization of sustainable development encompass the wider discourse on how solutions to needs of society can be not only economically viable, but also environmentally bearable, and socially equitable at the same time" (Medaglia & Damsgaard, 2020, p. 2). Through the course of the research, the authors identified aligned topics in four of the SDGs: Goal 9 - Build resilient infrastructure, promote inclusive and sustainable industrialization, and foster innovation; Goal 10 - Reduce inequality within and among countries; Goal 11 - Make cities and human settlements inclusive, safe, resilient and sustainable; and with a primary focus on Goal 16 - Promote peaceful and inclusive societies for sustainable development, provide access to justice for all and build effective, accountable and inclusive institutions at all levels (UN Brazil, 2024).

2. Theoretical Background

2.1 E-Government

The field of e-government evolved from Information Technologies (IT) usage in government, related to internal data processing and the inner workings of governments, to the adoption of ICTs, related to external processes, service provisions, or connections among different actors involved in smart governance (Grönlund & Horan, 2005; Heeks, 2001). Moreover, e-government is a plural field composed of multiple areas of study, such as smart governance (Meijer & Bolívar, 2015; Meijer et al., 2016; Przeybilovicz & Cunha, 2024; Tomor et al., 2019), e-participation (Cardullo & Kitchin, 2024; Cunha et al., 2013; Figueiredo et al., 2023; Muñoz & Bolívar, 2021; Przeybilovicz et al., 2022) or the digital divide and digital exclusion (Macaya et al., 2021; Schou & Pors, 2019; van Deursen & Helsper, 2015). Also, there is a growing literature about public value generated by e-government, such as improvements in public services, administration efficiency, citizens' well-being, or public trust in government. However, there is little research on the public value of e-government policies in developing countries, and fewer are still in the least developed ones (Twizeyimana & Andersson, 2019).

Heeks (2001) defines the contributions of e-governance into three domains, improvements in governments' inner processes, improving connections with citizens and digital services, and connecting with different actors in civil society. Twizeyimana & Andersson (2019) rearranged these domains into E-administration, E-services and E-citizens and E-society, thus increasing the importance of E-services to stand as their own domain and joining together E-citizen and E-society as a single domain. Multiple factors influence the adoption and acceptance of e-government policies (Hofmann et al., 2012). Those factors are different when considering the multiple actors involved in e-governance, for instance, trust in government, the type of technology chosen, or digital proficiency could have a direct impact on the adoption of a digital policy by citizens. Moreover, policy digitalization has a deeper impact on the roles of the actors involved and the nature of their interaction. (Lindgren et al., 2019).

Citizen's interaction and communication with the government changed with the internet due to multiple new

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

channels and services that began to be offered online. More than that, services that once required mediation through public officials at specific places and during work-hour time, could now be scheduled directly by citizens at any time and any place (Lindgren et al., 2019). But there is a barrier in the form of the technological artifact itself, and its capacity to adapt to the local context, that may hinder or improve accessibility. Technological artifacts should cater to the digital excluded by having a lighter, more responsive, intuitive, and accessible interface. Those characteristics would also improve the overall perception of the artifact, even to those that are not technologically excluded (Baatiema et al., 2023; Catalina-García & Galera, 2003; Kim et al., 2023; Zhang et al., 2022). The identification of the local needs can be critical for increasing the adoption of the artifact. Failing to identify the local necessities and dynamics could prevent users from engaging with the technology, for instance, such as with the lack of physical devices by low-income families in Argentina (Kim et al., 2023) or the instructions not being translated to Spanish when addressing Hispanic families in rural California (Schwal, 2022).

2.2 Digital Divide

Academic interest in the theme of digital exclusion arose in the 1990s and is directly linked to the digitization of governments and the increase in the use of the internet and personal computers. Since then, the concept of digital exclusion has been evolving, as well as technology and its relationship with society. The inability to use digital solutions happens when e-services are designed with the digital interface as the default or main channel of interaction, and it affects citizens at different levels of the digital divide (van Deursen & Helsper, 2015; Schou & Pors, 2019). Initially, the focus of the studies was only on access to the Internet, but currently, it is understood that digital exclusion occurs at three levels (Scheerder et al., 2017).

The first level of the digital divide regarded people who did not have access or connection to the internet. As technology became more accessible, the second level of the digital divide became more apparent as well, as it was related to the individual's ability to use technology. People who had access to technology and a connection to the internet could still be excluded due to not possessing the skills to use them. The third level of the digital divide comprehends people who have access to technology and the skills they could still be excluded due to not knowing how to extract concrete benefits from the use of the internet (van Deursen & Helsper, 2015; Scheerder et al., 2017).

The digital divide affects demographics and socioeconomic extracts differently. Factors such as gender, income, age, race, and education influence the likelihood of an individual being excluded (Helsper, 2010; Macaya et al., 2021). Segments of the population that already suffer from socioeconomic exclusion are most susceptible to facing digital barriers when accessing online governmental services that are designed with the digital interface as the standard or the sole interface (digital-by-default). In such cases, digital governmental services, such as online welfare, could reproduce existing inequalities for already disenfranchised populations (Allmann & Radu, 2023; Buchert et al., 2023; Schou & Pors, 2019).

3. Methodology

To help answer our research question, two case studies were conducted on municipal digital governance initiatives in different Brazilian contexts; one focused on citizen participation and the other on digital health. The "Ouvindo Nosso Bairro" program, initiated by the Salvador city government, is a participatory budgeting program that began in 2015. In 2017, the program was digitized through an online interaction platform with citizens, changing its format. The other case, the "Saúde Já Curitiba" program, is the digital health initiative of the city of Curitiba, launched in 2017. The "Saúde Já" app underwent several changes, including operational system changes and adaptations to meet new demands, such as those generated by the COVID-19 pandemic.

The data collection consisted of collecting primary and secondary data. The data were gathered through documentary research and interviews with program managers and participants. The articles "O pesquisador conversador no cotidiano" (Spink, 2008) and "Institutional vulnerability and trust in public agencies: Views from both sides of the street" (Spink et al., 2021) served as guides for the work and interactions in the field. Field diaries were produced with comments, perceptions, and dialogues with different actors during the field immersions. The interviews followed a snowball method in which initial contacts pointed to the next contacts for interviews. This method creates a chain sampling based on referrals from the initial interviews (Patton, 2014). Below are the documents collected for each case:

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Program	Primary data	Secondary data
Ouvindo Nosso Bairro Salvador	Semi-structured interviews with municipal managers and bureaucrats responsible for the program's implementation (7 interviewees in total). The interviews were conducted between October 2022 and January 2023.	Documents and official communications (18 documents from different sources), press releases, and articles about the program (5 documents from various sources).
	Semi-structured interviews with program participants and other citizens, such as local leaders, academics, and activists (14 interviewees in total). The interviews were conducted between October 2022 and January 2023.	
Saúde Já Curitiba	Semi-structured interviews with municipal managers and bureaucrats responsible for the program's implementation (5 interviewees in total). The interviews were conducted between November and December 2022.	Documents and official sources: Municipal Health Department, Municipal Council of Curitiba, Social Action Foundation, and Municipal Government of Curitiba.

Fig. 1 - Data collection for both programs. Created by the authors.

The data collection utilized in this research consisted of semi-structured interviews (primary data) and documentary research (secondary data). Data collection for both cases was approved by the Research Ethics Committee of FGV, the "Comitê de Conformidade em Pesquisas Envolvendo Seres Humanos" (CEPH). All research protocols followed meet the requirements of CEPH and adhere to research ethics. Audio recordings were transcribed, and key elements from the interviews were coded to analyze the data collected from them. The theoretical lens employed for data analysis of both cases was the Digital Divide. The field information is divided into a description of the two cases intertwined with quotes and excerpts from the data collection. In both cases, special attention was given to individuals at risk of being excluded from digital services, recognizing that the context and timing of digital programs can directly influence these citizens.

4. Case Studies

The case studies will be described chronologically. A timeline was created to compare both programs (Figure 2), and each case is described in its subsection.

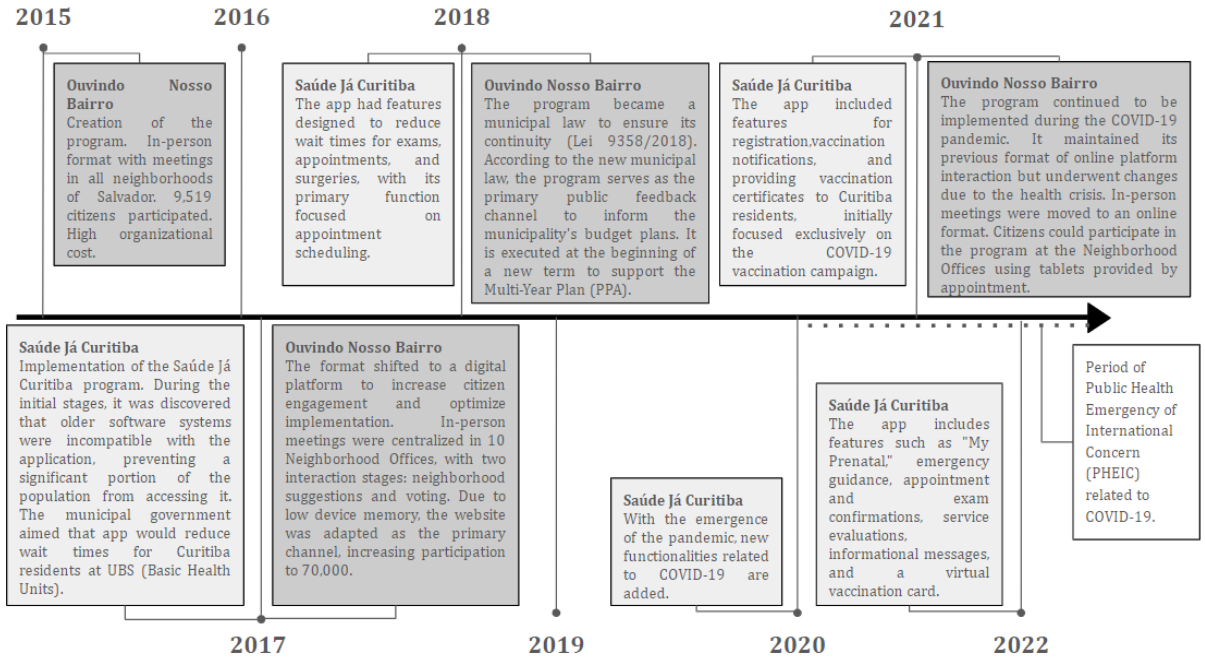

Fig. 2 - Comparative timeline of the Ouvindo Nosso Bairro and Saúde Já Curitiba programs. Created by the authors.

4.1 Ouvindo Nosso Bairro

The "Ouvindo Nosso Bairro" (ONB) policy was established in 2015 during a new management`s first term. The

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

implementation of the policy required significant political effort and was directly overseen by the mayor's office. The policy was an integral part of the administrative strategy to establish closer contact with the local population of Salvador. The first phase of the policy consisted of public hearings in each district of the city. Meetings were held at different times, on Wednesdays and Saturdays, in public places easily accessible to the local residents. In total, 152 meetings were held. (Matos et al., 2019; OGM - Ouvidoria Geral do Município, 2021). To ensure the continuity of the "Ouvindo Nosso Bairro" policy, it was passed as a municipal law by the city council, Law no. 9358/2018 This law requires the ONB to be conducted during the first year of a new municipal government term to substantiate the municipal budget plans (Gabinete do Prefeito Municipal do Salvador, 2018; Prefeitura Municipal do Salvador, 2021).

The second iteration of the policy took place during the administration's second term. This time, the administration brought a digitalization agenda and the ONB policy received a digital dimension through an online platform, created by the Companhia de Governança Eletrônica de Salvador (COGEL, literally translated as Electronic Governance Company of Salvador). This digital dimension aimed to increase the number of participants in the policy by centralizing participation in a smartphone application, and optimizing the implementation of the policy. The total number of participants increased from 9,519 participants to approximately 70,000. However, the policy lost part of its interaction. The face-to-face meetings held in each district were centralized at the ten subprefecture units (Matos et al., 2019).

The format of the "Ouvindo Nosso Bairro" changed due to its digitalization. The new format has four steps. The first step consists of citizens suggesting up to three infrastructure works for their neighborhood on the online platform. The results are then processed by the city hall and sent to the other secretariats, for technical and cost feasibility analyses. The approved results, based on the technical analysis, are returned to the citizens for voting on the online platform. At this step, citizens vote on their preferences from the approved list. After the voting is concluded, the results are published and the responsible secretariats start the most voted works for each neighborhood (Matos et al., 2019; Secretaria Geral de Articulação Comunitária e Prefeituras-Bairro, n.d.).

The administration took some precautionary measures regarding digital exclusion. The online process had the possibility of hybrid interaction and some key locations and public squares were equipped with free wifi connection for citizens. The hybrid policy worked with "Prefeituras-Bairro" units providing tablets and helping citizens participation. Also, city hall agents were positioned at high-traffic public places, equipped with tablets, to engage citizens to participate in the policy (Matos et al., 2019). After an initial test period, the administration found that the memory capacity of citizen's smartphones restricted the download of the application. So, the administration responded by modifying the ONB website to be more responsive, to accommodate all smartphones, and to become the main channel for interaction replacing the application. At the same time, a marketing campaign was launched aimed at informing citizens that the participation would take place through the policy's online webpage, as confirmed by interviewee 8:

Salvador is the city with most smartphones per habitants in the country (…) but, the idea of the application, was not a good idea. People had no memory on their cell phones, they used very simple cell phones, and that forced us to make a responsive system. Regardless of whether the citizen was on a very simple android, 16 gigs, or on a top-of-the-line iPhone, or on a top tablet, the system presented itself to him amicably and he could fill out the registration, and then fill in his answers in a simple manner. We didn't need citizens to download the application anymore, for them to participate. (…) we began to realize, during the first days, that we did not have a large number of downloads [of the application] in the stores, and we started to understand "hey, change that, turn the campaign now to just Access the Site" (Interviewee 8, "Ouvindo Nosso Bairro").

The digitization of the "Ouvindo Nosso Bairro" was inspired by the Digital Participatory Budget policy of Belo Horizonte (Matos et al., 2019). The Salvador administration was concerned with the voting fraud that happened at Belo Horizonte's policy, and this led them to adopt a different online user validation system. The Belo Horizonte policy validated the citizen's vote by the voter's title (Marquetti et al., 2008). For the "Ouvindo Nosso Bairro", validation occurs through the individual taxpayer ID number ("Cadastro de Pessoa Física", CPF). This process requires the validation of the citizen's document with the Treasury Secretariat's ("Secretaria da Fazenda") database and, if there is no parity, validation with the Special Department of Federal Revenue of Brazil's database is required, which incurs a cost, as stated by interviewee 8:

(…) These guys can start generating CPFs, do you know of CPF generators? All it takes is parity... And I said to the director that it's going to have a cost... If we need to criticize the CPF, that is one thing. You know, just to check the parity, whether it matches or not, so you let the guy in. But for you to make sure that the person exists, I have to go to the Treasury Secretariat. And if, for some reason, that person is not there in our base if it is in our base, it has no cost, understood? But if I have to get it from the Receita Federal [Federal Revenue of Brazil], I know it has a cost. So, the director said, "ok, we're going to do it". The first step was for the person to enter with their CPF, and then we validated if that person existed. (Interviewee 8, Ouvindo Nosso Bairro).

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

The third “Ouvindo Nosso Bairro” iteration took place in 2021. The policy continued with the same previous format, however, due to the COVID-19 pandemic, it had to be adapted to meet the sanitary restrictions. Synchronous meetings were maintained in an online format. Hybrid interactions still occurred within the 10 “Prefeituras-Bairro” units, upon prior scheduling by citizens. There was a reduction in the total number of participants to 53,882, combining approximately 21,000 votes from the online suggestion stage and 32,000 votes from the online voting stage (Secretaria de Comunicação, 2021b, 2021a).

4.2 Saúde Já Curitiba

Before understanding the Saúde Já Curitiba program and, more importantly, its rapid adaptability, it is necessary to observe that digitizing healthcare has been ongoing since 1999. Saúde Já Curitiba is just one element of this process. In 1999, an information system was implemented throughout the Primary Care Network. The system, then Cartão Qualidade Saúde (CQS), integrated citizen records, establishments, and procedures based on the patient's electronic medical record. CQS pioneered capturing reliable real-time information, facilitating the monitoring of the work process (Secretaria Municipal de Saúde de Curitiba, 2023a). In 2012, CQS was replaced by e-Saúde, a system still in use (as of May 2023). Beyond the functions that CQS already performed, e-Saúde also integrated all areas of the Municipal Health Secretariat into a single system: Primary Care; Urgency and Emergency; Dentistry; Epidemiological and Sanitary Surveillance; Control; Evaluation; Audit; and Regulation. During interviews, elements of a more applied and comprehensive vision of digital health were sought, especially regarding how managers assess the integration of digital resources into the community and healthcare infrastructure. As demonstrated by Interviewee 2 (Saúde Já) in this interview excerpt:

If I have good facilities, good technology equipment to treat the patient there: take an X-ray, do a CT scan... But also information about that patient, I can better understand their problem, and solve their problem, right? But at the same time, when I build a system like this, no matter how first-world it may be, no matter how fantastic it is... In terms of applied technology, it is useless if it does not consider [for instance] whether Dona Francisca, who lives in Caximba [a poor neighborhood of Curitiba], will benefit from it. If I start from the premise that I will add technology and shift in-person care to other activities, I will leave these people without care and not improve their care. (Interviewee 2 - Saúde Já).

Starting this greater integration of citizens with the system in 2017, the Municipal Government of Curitiba, under pressure from the mayor, implemented the Saúde Já App. Initially, the main concern was eliminating early morning queues for scheduling appointments at UBS. The app then began to function for appointment scheduling. However, in the first few months, it was noted that a large portion of the population could not access Saúde Já because users used smartphones with much older software than what the app supported, causing Saúde Já not to run or even download on these devices. Here, we have the first major transformation of the Saúde Já app: the configuration was changed to make the app compatible with all smartphone operating systems. Interviewee 3 (Saúde Já) reflects on the use of tools and technological innovations in healthcare without falling into the trap of "innovating just for the sake of innovation," especially when considering the perspective of public health:

You need to work with a healthcare system that accommodates technological innovations, but technological innovations have to be designed to serve something... they have to make a difference, and that's where our app became this great link." (Interviewee 3 - Saúde Já)

The Municipal Health Plan of Curitiba 2022-2025 (Secretaria Municipal de Saúde de Curitiba, 2023b) highlights that the Saúde Já app, in addition to scheduling appointments, has new functions. One is the "Meu Pré Natal" (My Prenatal) function, aimed at pregnant women, providing information about pregnancy stages, including a contraction calculator to indicate the right time to go to the maternity ward during childbirth. Another function is guidance for urgent cases, including traffic accidents, medical and dental emergencies, sexual violence, and HIV contact. Furthermore, the app offers appointment and exam confirmations, with a history and transaction code stored within the app, and the ability to evaluate any care provided in the UBS or the service provider network. There are also informative messages about health programs and actions conducted in the UBS, as well as a virtual vaccination card that includes vaccination history, pending vaccinations, and notifications of vaccination campaigns. In 2020, with the COVID-19 pandemic, integration with the Telemedicine Center was added, as part of the pandemic response strategy, along with medical video consultations, general health service guidance, appointment scheduling, and system e-health registration updates. Thus, the pandemic forced the second transformation of Saúde Já Curitiba, adding these new and important features to combat the pandemic.

Impacted by the adaptations required to address the pandemic spread of COVID-19, the search for the expansion, qualification, and modernization of public health services is reflected in products and services aimed at integrating technology into humanized healthcare in Curitiba: connectivity, intelligence, and database applied for the benefit of the population. Electronic medical records, video consultations, and telehealth services are aligned with new initiatives for specialized care and health surveillance, marking the evolution of services in all their breadth (Secretaria Municipal de Saúde de Curitiba, 2023b, p. 158). This discourse of adaptation and innovation is observed

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

in the projects, guidelines, and approved proposals in the Municipal Health Plan of Curitiba 2022-2025 (Secretaria Municipal de Saúde de Curitiba, 2023c).

4.3 Cases intersections

Both the "Ouvindo Nosso Bairro" and "Saúde Já Curitiba" programs have shown the importance of the municipal management's concern with the digital divide, and how it molded both programs. In Salvador, the management had to adapt to the difficulties imposed by digitization. Their initial internet access precautions were insufficient for the population to participate in the program. The technology had to be adapted to the local population's hardware restrictions. The city's administrations changed the channels of interaction with the program, from the application to the website, and made it more responsive to all devices. The "Saúde Já Curitiba" program also faced difficulties with older operating systems. The application had to be adapted to work on all operating systems to serve the city's entire population. Figure 3 illustrates the relationship between the challenges faced in both cases and also links them to the three levels of digital exclusion.

CHALLENGES			
	First level/internet access divide People who do not have access or connection to the internet	**Second level/skills divide** People who are unable to use digital tools	**Third level/beneficial outcomes of Internet use** People who are unable to gain real-world value or benefits from their use of technology
Ouvindo Nosso Bairro Salvador	- Low memory capacity of the smartphone devices - Lack of internet access by part of the population	- Illiteracy rate among the adult population of Salvador. - Citizen's struggle with using and understanding the website.	- Citizens don't have a long-term memory and understanding of the policy. - Citizens don't know about the policy's existence. - Citizens being manipulated by local leaders into voting without fully understanding the policy. The policy became a "Local leader's dispute" for their work.
Saúde Já Curitiba	- Users had smartphones with much older software than what the app supported - Lack of internet access by part of the population	- Citizens struggle with creating an account, logging in and/or solving technological problems	- Lack of knowledge among citizens to address their health issues using the available tools - Citizens did not see benefits in using an app rather than going to the UBS

Fig. 3 - Comparative challenges of the Ouvindo Nosso Bairro and Saúde Já Curitiba programs. Created by the authors.

During the pandemic, "Saúde Já Curitiba" incorporated sanitary guidelines and was integrated with the Telemedicine Center. On the other hand, "Ouvindo Nosso Bairro" underwent adaptations to continue running, despite the difficulties imposed by the sanitary requirements. Synchronous meetings were held in digital format and, to assist the population with challenges, the program continued to be run in a hybrid format by appointment. These and other solutions (Figure 4) were necessary for the continuity of the programs and the increase in engagement.

SOLUTIONS			
	First level/internet access divide People who do not have access or connection to the internet	**Second level/skills divide** People who are unable to use digital tools	**Third level/beneficial outcomes of Internet use** People who are unable to gain real-world value or benefits from their use of technology
Ouvindo Nosso Bairro Salvador	- Migration from the application platform (required higher memory to download) to a webpage. - The web page's interface was made lighter to facilitate user access and voting. - Free internet access points were installed at key locations of the city. - Hybrid policy: on-site city officials were positioned at key locations in Salvador with a tablet to help citizens participate in the policy. It was also possible to participate locally at each Prefeitura-Bairro unit.	- Hybrid policy: on-site city officials at key locations of Salvador and Prefeitura-Bairro street-level bureaucrats would help people with participation. - The webpage interface was made easier and simpler for citizen registration and interaction. - Backoffice: Validate citizens' registration through their CPF (Individual Taxpayer Registration) with the Receita Federal (Federal Revenue) database.	- Disclosure of the policy through media/social media channels. - Disclosure of the different steps of the policy, from voting to implementation and work inaugurations.
Saúde Já Curitiba	- The app configuration was changed to make the app compatible with all smartphone operating system	- The Telemedicine Center with a phone number was created to address citizens' accounts and technological problems	- Increased promotion of the Saúde Já Curitiba app - Mandatory use of the app during the COVID-19 vaccination program - Addition of more features and services

Fig. 4 - Comparative solutions of the Ouvindo Nosso Bairro and Saúde Já Curitiba programs. Created by the authors.

The "Ouvindo Nosso Bairro" and "Saúde Já Curitiba" cases demonstrate the importance of addressing the digital divide through the adaptation of municipal policies. Both faced technological challenges, such as hardware and operating system limitations, which required shifts to more inclusive platforms. During the COVID-19 pandemic, the programs showcased resilience by integrating telemedicine and hybrid participation formats, ensuring continued service and engagement. Figures 3 and 4 highlight how these challenges and solutions addressed the three levels of the digital divide.

5. Discussion

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

The cases studied exposed the need for adaptations when introducing new technologies to the population. Both programs were able to adapt to better meet the demands and needs of their citizens. Beyond the cases mentioned, it is highlighted that digital government practices must ensure that public services are planned and provided in such a way that the benefits of digital transformation are available and accessible to all, including those who depend on face-to-face interactions. Therefore, it is necessary to look both inward and address the context and governance (such as administrative structures), as well as outward, focusing on the needs of users throughout their experience with public service, regardless of whether it is delivered by mail, telephone, in person or through a digital device (Welby and Tan, 2022). Each e-policy studied faced challenges during its launch and only managed to have a higher number of users once they were adapted to minimize the local barriers, confirming the need for adaptation of e-policies to its context to reach a higher number of people (Baatiema et al., 2023; Catalina-García & Galera, 2003; Kim et al., 2023; Zhang et al., 2022).

The COVID-19 pandemic was a period that forced the digitalization of many municipal services. Successful policies during the pandemic were the ones that understood their contextual challenges regarding the digital divide and adapted the program, especially through the use of more responsive interfaces and the inclusiveness of different channels and devices for communication with citizens (Acosta-Vargas et al., 2022; Baatiema et al., 2023; Kim et al., 2023). The different levels of the digital divide created barriers that needed to be addressed by the municipal government for their policies to reach a higher number of users. In both cases, citizens already had access to technology in the form of smartphones and yet, due to the diversity of the types of smartphones, the policies did not originally reach citizens. Smartphone limitations, such as the memory capacity, or older models with outdated versions of the operation system, were major limitations in the technology that required the policies to be redesigned. When considering the different levels of the digital divide, the redesigns of the policies were aimed to address the first and the second levels by providing more access to citizens, either through alternative channels, by asynchronous and on-premise attendances, or by adapting the e-policy/platform to cater to more devices. However, the third level of the digital divide (van Deursen & Helsper, 2015) did not receive that much attention from the municipal governments and it was only partially considered through the disclosure of the policies.

The digital divide is more nuanced than just the three levels mentioned above, such as the characteristics of the population and of the local context and how they impact citizens' accessibility and use of e-services (Macaya et al., 2021). However, both e-policies studied did not account for these nuances in their actions toward mitigating the digital divide and increasing the policies reach to the population. We positioned that the e-policy should incorporate strategies to reach out to these different population strata to overcome the digital divide. For instance, Panganiban (2018) showed how simple solutions tailored to a specific population increase the reach of an e-policy, such as creating a more informal setting for an ICT teaching center that would encourage a shy and rural population for attend it, or incorporating already known technologies instead of proposing new ones.

Answering the Research Questions

Through the two case studies, it was possible to draw some conclusions about the policy designs that helped the digital policies reach a higher number of citizens by addressing the digital divide at different levels, thus answering our initial question, “How can digital public policies be designed to maximize citizen engagement and ensure equitable access to services, while addressing systemic inequities and adapting to local socioeconomic and technological contexts? The following suggestions compile our findings in e-policy design and also answer our secondary questions on possible mechanisms that improve the reach to citizens by addressing the digital divide. These recommendations are also responding to Madsen et al. (2014) in the need for bridging research in e-government with practice:

- Backoffice: municipalities may experience hardships with database parities when validating citizens' registration in the e-policy. A possible solution is to validate the ID with a citizen registration database at the federal level, such as with a federal revenue agency. Validation is important to guarantee the safety of the users as well as the validity of the e-policy.

- Policy design addressing the first level of the digital divide: responsive and lighter interface. Prepared to run on multiple platforms, either by web browser or applications that are light (low-memory consumption and responsive) and can run on multiple operating systems, even in older, outdated versions. Also, on-premises possibilities for technology use and access at key locations are important to guarantee access to technology and to the internet in contexts where they are not easily available to all citizens.

- Policy design addressing the second level of the digital divide: all e-services should be hybrid with on-premise and other types of asynchronous citizen support, such as telephone channels. The more different types of channels supported, the easier it will be for citizens to troubleshoot or access assistance in using the e-service, as well as accessing the service offline in traditional on-premise formats.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

- Policy design addressing the third level of the digital divide: the third level of the digital divide is more challenging to address. Different mechanisms were employed in the cases studied to instigate a long-term memory and understanding of the policy, but some of the results were not fully successful. Those mechanisms included investment in the disclosure of the policy through different media/social media channels, mandatory use of the application during the COVID-19 pandemic, and even the addition of more features to the application/e-service. We argue that there should be more public deliberation with citizens to better explain the e-service, and e-services in general, to raise their awareness, especially targeting segments of the population that face more challenges in accessing and understanding e-services, based on race, age, gender, income, and education (Macaya et al., 2021).

6. Conclusion

The study addresses the role of municipal governments in designing equitable digital public policies while dealing with a partially digitally divided population. It also underscores the critical need for adaptive and inclusive digital public services, policies, and programs so citizens do not become unassisted of basic government services - for example, in Saúde Já Curitiba, the program ensures public health access. By analyzing the "Ouvindo Nosso Bairro" and "Saúde Já Curitiba" programs, the article highlights the challenges and solutions in implementing inclusive e-services and it becomes evident that municipal governments must account for local technological, socioeconomic, and contextual barriers to ensure broader citizen engagement.

The study emphasizes the importance of designing digital services that address all three levels of the digital divide: access, skills, and outcomes. Local adaptability emerged as a crucial factor, demonstrated by the implementation of responsive platforms, hybrid access models, and user-centered designs that cater to diverse population needs. As happened during the COVID-19 pandemic, when both programs showcased resilience by incorporating innovative solutions such as the Telemedicine Center and hybrid participation formats, ensuring continuity and inclusivity. From these findings, critical lessons for policymakers include the necessity of hybrid approaches that integrate digital and in-person services to enhance accessibility, the importance of iterative adjustments that account for local technological and socioeconomic contexts, and the need to go beyond access by addressing digital literacy and fostering the meaningful use of technology. These insights underscore the importance of adaptability and inclusivity in the development of effective digital public policies.

Following Twizeyimana & Andersson's (2019) main application domains of e-policies, our findings were concentrated in the e-service domain. More research could be done specifically looking at the other domains. Specifically, more research on the E-Administration domain could help understand the impacts of the digital divide and possible solutions to mitigate them from the inner perspective of the government. Also, more research on e-service at the local level could improve our findings with different inputs from other cases and experiences in how e-policies could be adapted to answer the digital divide.

Submitted: 31 January 2025, Revised: 26 March 2025, Accepted: 21 April 2025, Published: 26 May 2025

Abstract. This article presents the implementation of the Unified Public Administration System (SUAP) in technical schools across the State of Mato Grosso, Brazil, as a key initiative in the state government's digital transformation strategy. Developed in collaboration with UFMT, IFMT and SECITECI, the project aimed to modernize educational governance by replacing fragmented, manual processes with a centralized, cloud-based platform. By integrating SUAP into school administration, the initiative enhanced transparency, streamlined workflows, and standardized digital services across urban and rural institutions, reinforcing social cohesion and reducing regional disparities in access to technology. The project addressed critical challenges such as infrastructure limitations, data security, and resistance to change. Custom solutions were implemented, including improved Moodle integration and enhanced SUAP functionalities for certificate management and user permissions. A collaborative, agile approach guided the development process, ensuring that technical teams, policymakers, and educators worked together to build a robust and scalable system. Additionally, a comprehensive capacity-building program equipped staff and students with the necessary digital literacy skills to maximize system adoption. Results demonstrated significant impact, with 719 students, 124 technical staff, and 190 teachers actively using the system, alongside the migration of over 800 historical records. By aligning with the State of Mato Grosso Digital Strategic Agenda (2023–2027), this initiative exemplifies how subnational governments can leverage digital transformation to optimize public services, enhance institutional efficiency, and foster digital inclusion. The success of SUAP in Mato Grosso provides a replicable model for other regional administrations seeking to modernize governance and ensure equitable access to digital public services.

Keywords. Applied computing, E-government, Information systems, Public Education Modernization
Research paper, DOI: https://doi.org/10.59490/dgo.2025.965

1. Introduction

Efficiency in public administration is inherently tied to the ability to deliver services effectively while optimizing resources. Digital transformation plays a crucial role in this process by integrating technologies that

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

enhance resource management and enable the development of more innovative services (Daßler et al., 2024). The implementation of digital systems allows real-time monitoring of service and project execution, thereby reducing inefficiencies and increasing transparency in public policies and resource management. However, the adoption of these technologies often faces resistance, particularly due to inadequate infrastructure and insufficient professional training, factors that may limit their expected positive impact on service quality (Silva et al., 2019).

In the context of public schools, the Unified Public Administration System (SUAP) was created in 2006. The Federal Institute of Rio Grande do Norte (IFRN) has continuously improved this software platform as a solution for digitizing administrative and academic management in public institutions. Over the years, SUAP has evolved to meet the needs of schools, universities, federal institutes, and other public organizations throughout Brazil. With a robust set of features, including approximately 24 modules designed to support institutional management, the system offers tools tailored to different user profiles, such as administrative staff, students, and contractors. By prioritizing usability, SUAP ensures an intuitive and accessible interface, establishing itself as an effective tool for institutions seeking to modernize their administrative and academic practices (Costa, 2016).

Due to its functionalities and efficiency in various institutions, SUAP was introduced into technical schools in the state of Mato Grosso as part of the project presented in this work. The SAEPT project aimed to modernize administrative and academic management through digital technologies such as cloud computing. Developed in partnership with the Institute of Computing (IC) at Federal University of Mato Grosso, Federal Institute of Mato Grosso, and the Mato Grosso State Department of Science, Technology, and Innovation (SECITECI), the project sought to improve the efficiency of school management activities, focusing on the organization of teaching and administrative processes.

This paper is organized into four main sections, in addition to this Introduction. The next section, titled *Research Methods*, outlines the objectives, methodologies, and processes used to implement SUAP and the associated technological improvements. *Background* provides an overview of the context and main challenges faced by the technical schools in the State of Mato Grosso, highlighting the need for modernization and improved management systems. In *Results and Discussion*, the outcomes of the project are presented, emphasizing the impact of SUAP on administrative efficiency and educational management. Finally, *Conclusion* reflects on the project's achievements, lessons learned, and its broader implications for the modernization of public administration and technical education.

2. Research Methods

The implementation project of the **Sistema de Gestão das Escolas Técnicas Estaduais (SAEPT)**, linked to the research project *"Application of Cloud Computing Technologies to Educational Management Environments"*, was initiated with its first meeting on January 8, 2024. This project aimed to enhance educational management through the integration of cloud computing technologies, focusing on the development and implementation of a robust Academic Management System tailored to the needs of technical schools in the State of Mato Grosso. The project was developed in partnership with the **Institute of Computing (IC)** at the **Federal University of Mato Grosso**, the **Federal Institute of Education, Science and Technology of Mato Grosso**, and the **Mato Grosso State Department of Science, Technology, and Innovation (SECITECI)**. The primary objective was to create a technological solution capable of streamlining administrative and academic processes while ensuring efficiency, scalability, and user satisfaction.

2.1. Project Phases and Methodological Approach

The project was structured into nine distinct phases, each designed to ensure a systematic and comprehensive implementation of the SUAP system. These phases are outlined below:

1. **Data Collection and Requirements Analysis**: This initial phase involved gathering data and analyzing the specific requirements of the technical schools. It included understanding existing administrative and academic processes, identifying pain points, and defining the functional and non-functional requirements for the new system. Workshops and interviews with stakeholders were conducted to ensure a comprehensive understanding of institutional needs.

2. **System Design and Customization**: Based on the collected data, the team designed and customized the SUAP system to meet SECITECI's specific requirements. This phase included developing new modules, adapting existing features, and integrating the system with platforms such as Moodle for online learning.
3. **Cloud Service Deployment and Monitoring**: The core system was deployed on a cloud infrastructure to ensure scalability and reliability. This phase involved configuring virtual machines, setting up load balancers, and implementing continuous monitoring tools to track system performance and identify potential issues in real time.
4. **System Adaptation and Optimization**: The system was further adapted to address the unique needs of individual school units. This included optimizing the user interface for different roles (students, teachers, and administrative staff) and configuring specific features such as certificate management and user permissions.
5. **Data Migration and Security**: A critical phase involved migrating historical data from legacy systems to the new platform. This process required careful planning to maintain data integrity and security. Measures such as encryption and access controls were implemented to safeguard sensitive information.
6. **System Testing and Evaluation**: Comprehensive testing was conducted to evaluate the system's performance, usability, and reliability. This included functional testing, stress testing, and user acceptance testing (UAT) to ensure the system met predefined requirements and was deployment-ready.
7. **Training and Capacity Building**: To facilitate a smooth transition, comprehensive training sessions were organized for the SECITECI IT team and end-users, including teachers, students, and administrative staff. Training materials, such as manuals, video tutorials, and interactive workshops, were developed to support user adoption.
8. **On-Site Support and Troubleshooting**: The project team provided on-site support to resolve technical issues during the initial deployment phase. This included troubleshooting, bug fixing, and real-time assistance to ensure the system operated as intended.
9. **Final Reporting and Documentation**: In the final phase, a detailed project report was prepared, documenting all stages of the implementation process, lessons learned, and recommendations for future improvements. This report serves as a valuable resource for ongoing system maintenance and scalability.

To better illustrate the sequence of interactions between the State Government, researchers, cloud infrastructure, and end-users throughout the project phases, Figure 1 presents a structured workflow diagram.

2.2. Team Structure and Collaborative Approach

The project team was organized into three main groups, each with distinct responsibilities:

- **Mapping Team**: This team documented and structured the administrative and academic processes of the technical schools. Using the **HEFLO** tool, they created detailed flowcharts in BPMN (Business Process Model and Notation) format, providing clear visualizations of workflows and identifying areas for improvement. These flowcharts were crucial for aligning the SUAP system with the actual needs of the schools.
- **Training Team**: Focused on capacity building, this team developed instructional materials and organized training sessions for diverse user groups. They created comprehensive manuals, video tutorials, and interactive workshops. The team also leveraged the **Moodle** platform to deliver online training courses, enhancing accessibility and flexibility for users.
- **Infrastructure Team**: Responsible for the technical implementation of the system, this team managed server configuration, network setup, and security measures. They ensured the system was deployed on a robust and scalable cloud infrastructure, implementing features such as data backup, redundancy, and disaster recovery. The team also configured firewalls, SSL certificates, and external monitoring tools to guarantee the system's security and reliability.

2.3. Agile Methodology and Project Management

The project adopted an **agile methodology**, specifically the **Scrum framework**, to manage tasks and ensure timely delivery. Scrum was selected for its ability to foster collaboration, increase productivity, and adapt to

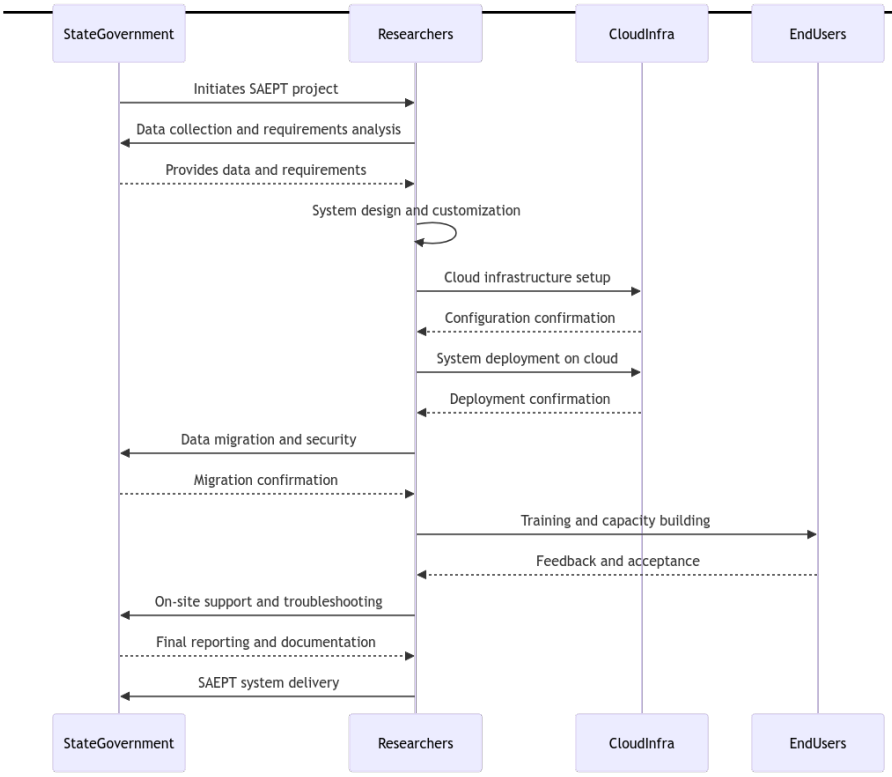

Fig. 1 – Sequence diagram of the SAEPT project phases and interactions.

changing requirements. The project was divided into **sprints**, each lasting two weeks, during which specific tasks were completed and reviewed. The use of **OpenProject**, a free software tool integrated with Scrum, facilitated task management, progress tracking, and communication among team members.

The agile approach allowed the team to quickly respond to feedback and make necessary adjustments throughout the project. Regular sprint reviews and retrospectives assessed progress, identified challenges, and implemented improvements. This iterative process ensured the final product met stakeholder needs and was delivered within the agreed timeline (Lages et al., 2024).

2.4. Communication and Project Management Tools

Effective communication and project management were essential for the successful implementation of the SAEPT project. Figure 2 illustrates the various tools and processes employed to ensure seamless collaboration and efficient management. **Meetings** were regularly scheduled to define objectives, establish actions, and record minutes, ensuring alignment among all team members. **OpenProject** was utilized to manage resources, control deadlines, and organize tasks, offering a comprehensive platform for tracking progress. For **training**, the Moodle platform facilitated certificate issuance, course delivery, and performance evaluation. Additionally, **Heflo** was employed to map workflows and monitor key performance indicators (KPIs). The **support team** played a vital role in maintaining infrastructure, providing technical assistance, automating processes, and managing the network. This structured approach was instrumental in maintaining project momentum and ensuring its successful completion.

2.5. Challenges and Solutions

One of the main challenges encountered during the project was **resistance to change** from some users, particularly those accustomed to manual processes. To address this, the training team developed tailored programs and provided ongoing support to help users transition to the new system. Additionally, a **support channel** was implemented to allow users to report issues, ask questions, and receive real-time assistance.

Another significant challenge was ensuring **data security and privacy**, especially given the sensitive nature of student and staff information. The infrastructure team implemented robust security measures, including

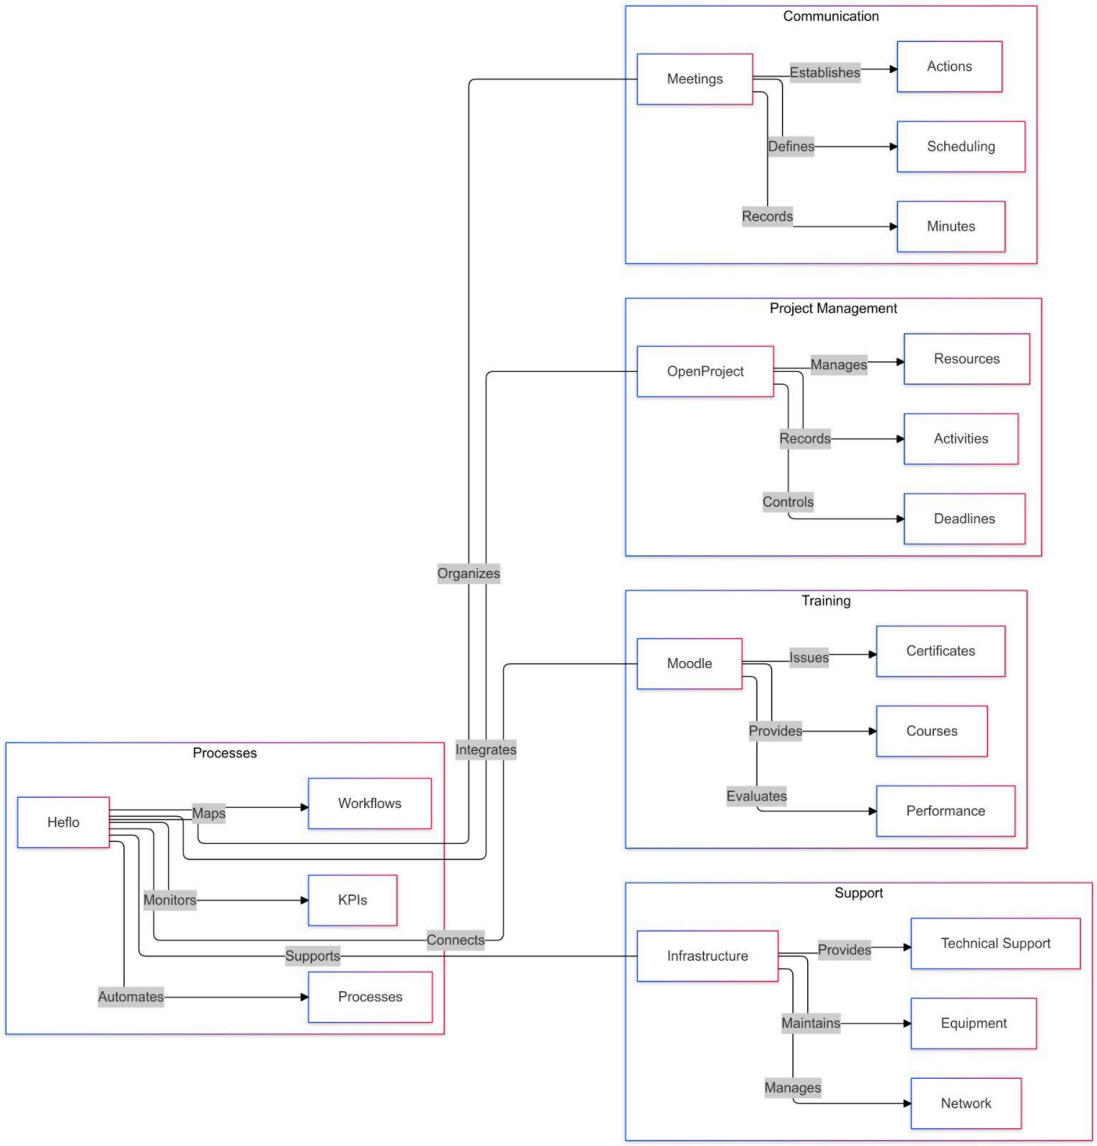

Fig. 2 – Diagram illustrating communication, project management, training, and support tools used in the SAEPT project.

encryption, access controls, and regular security audits, to protect data and ensure compliance with relevant regulations.

The methodological approach adopted in this project underscores the importance of a **collaborative and iterative process** in implementing complex technological solutions. By combining agile project management, detailed process mapping, and comprehensive training, the team successfully deployed the SUAP system in Mato Grosso's technical schools. This approach not only ensured the system's implementation but also established a foundation for future scalability and continuous improvement.

3. Background

The State of Mato Grosso, Brazil's third-largest by territorial extension, spans 903,357 km^2 in the central-west region. Its geographic and cultural richness is unparalleled, encompassing three globally significant biomes: the Amazon Rainforest, the Pantanal wetlands, and the Cerrado savanna. This biodiversity hotspot coexists with a multicultural heritage shaped by African, Portuguese, Spanish, Indigenous, and Chiquitano influences, fostering a unique socio-environmental identity (Prates, 2014). Despite efforts to preserve Indigenous traditions and ecosystems, the state's economic backbone—agribusiness and commodity exports—has driven

rapid urbanization and infrastructure demands. Between 2002 and 2022, Mato Grosso emerged as Brazil's fastest-growing state economy, increasing its share of the national GDP by 1.2 percentage points, a testament to its strategic role in national development (Instituto Brasileiro de Geografia e Estatística (IBGE), 2024).

However, this growth has exacerbated regional disparities. The state's vast territory, while economically productive, poses significant challenges for equitable access to public services, particularly in remote municipalities. Rural-urban divides are stark: while urban centers like Cuiabá (the capital) benefit from advanced infrastructure, rural areas struggle with limited connectivity and institutional support. These disparities extend to the education sector, where technical schools—Escolas Técnicas Estaduais (ETECs)—play a pivotal role in bridging workforce demands and vocational training.

Fig. 3 – State Technical Schools of Mato Grosso: Contrasting infrastructures. Left: ETEC Poxoréo (rural focus on agriculture); Right: ETEC Cuiabá (urban courses in IT, healthcare, and administration). Adapted from (Secretaria de Ciência, Tecnologia e Inovação de Mato Grosso (SECITEC), 2024).

As illustrated in Figure 3, the dichotomy between rural and urban ETECs reflects the state's socio-economic contrasts. ETEC Poxoréo, located 250 km from the capital, prioritizes agricultural and animal husbandry programs tailored to local agrarian needs. In contrast, ETEC Cuiabá offers advanced courses in Information Technologies, Nursing, and Occupational Safety, supported by modern IT infrastructure. This disparity underscores the need for adaptable administrative systems capable of addressing diverse regional requirements while maintaining statewide coherence.

The 17 ETECs across Mato Grosso currently serve approximately 1,750 students through partnerships between the State Department of Science, Technology, and Innovation (SECITECI) and the State Education Secretariat(SEDUC). By 2025, the network aims to expand to 4,000 enrollments across 25 courses, including integrated high school programs and post-secondary vocational training (Téo Meneses, 2024). Yet, until recently, administrative practices lagged behind these ambitions. Manual processes, such as spreadsheet-based student record-keeping, dominated operations, leading to frequent errors, data fragmentation, and inefficiencies in interdepartmental coordination. These limitations hindered scalability and contradicted the state's modernization goals.

To address these challenges, the Government of Mato Grosso launched its Digital Strategic Agenda (2023–2027) through Decree No. 338/2023. This policy framework prioritizes digital transformation in pub- lic administration, emphasizing bureaucracy reduction, innovation, and cross-sectoral technological integration (Governo de Mato Grosso, 2023). Within this context, the Unified Public Administration System (SUAP) emerged as a cornerstone for modernizing technical education management. Originally developed by the Federal Institute of Rio Grande do Norte (IFRN) in 2006, SUAP's modular design and focus on usability align with Mato Grosso's objectives to streamline workflows, automate certificate issuance, and centralize data across geographically dispersed institutions. By adopting SUAP, the state aims to harmonize its dual identity: preserving regional specificity while advancing toward a digitally unified governance model.

4. Results and Discussions

The team, divided to meet the project's demands within the agreed timeline with the institution, carried out its activities in an integrated and focused manner to achieve the project's objectives. Each team played specific yet complementary roles that were essential to the initiative's success.

With the deployment of all software tools, the teams adopted an agile methodology akin to Scrum to carry out the overall activities. The workflow was structured into groups of sprints, with each sprint spanning two weeks. Each team developed a backlog listing all deliverables, which were then prioritized and allocated to specific sprints. New requests were added to the backlogs as they arose and followed the same process.

The Mapping team was responsible for creating detailed workflows using the Heflo software tool, mapping the steps for utilizing the system's functionalities, such as adding sectors, enrolling students, and other activities. Figure 4 illustrates one of these workflows, detailing the process of enrolling in a school diary. The process begins with navigating through the "Teaching" menu, followed by searching for and selecting the student, and culminating in the confirmation of the enrollment. Complementing this work, PDF manuals enriched with images were created to clearly explain the system's features. These initiatives not only facilitated user understanding but also enabled the team to perform system testing, ensuring its functionality and alignment with the project's requirements.

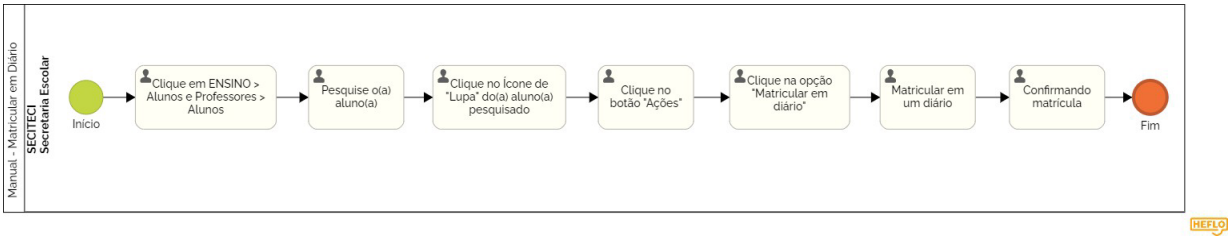

Fig. 4 – Example of process mapping: Enrollment in a course

Additionally, the team developed a website with the goal of centralizing and providing support materials in a practical and accessible manner. In Figure 5, it is possible to see that the homepage of the site presents tutorials and workflows detailing the system's functionalities, providing easy access to essential information. The platform organizes PDF manuals, tutorial videos produced by the training team, as well as news related to the training sessions. The site was structured into specific sections covering administrative features, teachers, students, training, and process workflows, allowing intuitive navigation and targeted support for the different needs of users.

Fig. 5 – Home page of the website of the project, where tutorials and workflows detailing the system's functionalities are readily available.

I record the administrative and pedagogical processes of the institutions, such as school registration actions, teachers' activities, and the organizational structure of schools and the SECITECI headquarters. These assessments were crucial in adjusting the system to the specificities of each institution, ensuring that the main routines were taken into account. Furthermore, the team created detailed flowcharts of the planned interactions for the new system, using the Heflo tool to generate BPMN-format mappings. These diagrams documented steps such as the student's first access to the system, overall grade history, and teachers' use of the class journal, among others. The flowcharts played a strategic role, serving not only to validate the system but also as training material for users, facilitating the understanding of functionalities by both students and staff.

The training team devoted itself to the capacity building of different user groups, including managers, teachers, students, and administrative teams from state technical schools and SECITECI. Their activities focused on creating instructional materials, manuals, and in-person and online training sessions to ensure a smooth transition and mastery of the system's functionalities by the involved parties. The manuals developed included

detailed, step-by-step guides for various system operations that are essential to the daily routines of technical school units, as can be seen in Figure 6. These operations included ticket submission, grade entry, transfers, enrollments, and the issuance of certificates and diplomas, among others. Additionally, the team produced materials specifically tailored for students, covering actions such as system access, grade consultation, and credit recognition requests.

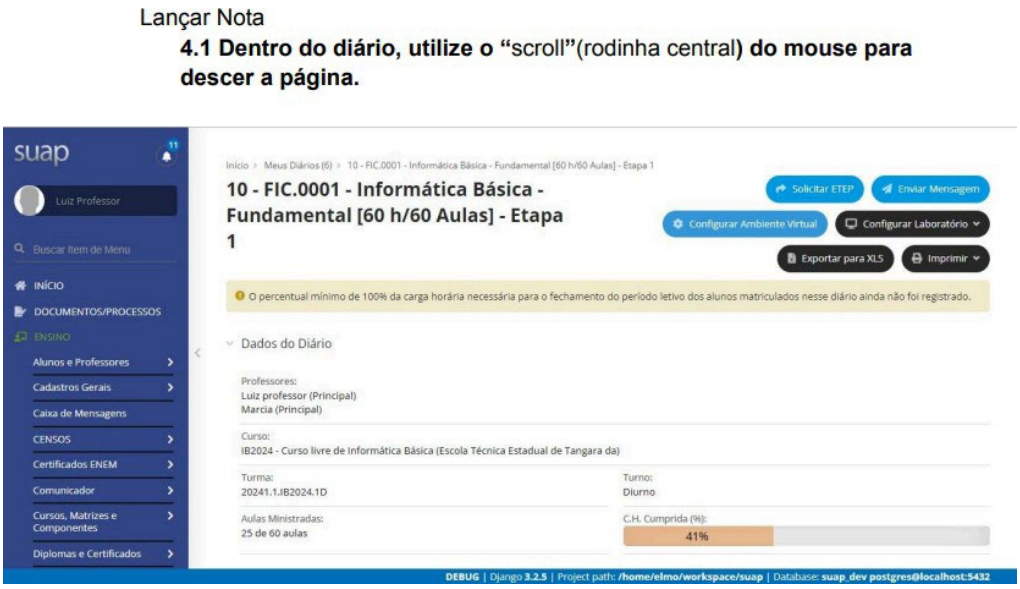

Fig. 6 – Example of PDF Manual: How to Enter Grades.

A notable highlight was the creation of multimodal content, including tutorial videos and diagrammed presentations, which significantly facilitated the assimilation of information. The team developed scripts, recorded and captioned video lessons, and configured a Moodle platform for course delivery. These materials were further enriched with asynchronous content, available in both video and PDF formats for future reference. Interactive resources, such as Kahoot quizzes, were also employed to provide a dynamic and engaging learning experience. This combination of synchronous and asynchronous learning formats enables a more personalized educational journey, catering to the individual needs of students and fostering self-directed learning (Chernov et al., 2021). As illustrated in Figure 7, an example of a video tutorial published on YouTube by the training team showcases this approach. In total, 47 tutorials were produced, combining text and video formats, covering the main functionalities of SUAP. These resources were designed to train users and ensure the efficient use of the system (Universidade Federal de Mato Grosso & Núcleo de Tecnologia da Informação (NUTI), 2024).

Fig. 7 – Example of a video tutorial published on YouTube by the training team.

Tr ts, including in-person sessions, online synch hese varied formats allowed the training to

reach a diverse range of users effectively. Thus, the methodology was tailored to meet the specific needs of each group, with personalized training for managers, teachers, and administrative staff. In Figure 8, one of the in-person training sessions held with school managers is highlighted. The environment fostered direct interaction between participants and the training team, creating a conducive space for addressing questions and collaborative learning. During these sessions, participants received guidance on critical functionalities and had the opportunity to ask questions about the use of the SUAP system. The Moodle platform was used as the main training environment. This included creating specific courses for each audience, preparing classes with test student data, organizing content into stages, and adding explanatory videos and PDFs. This effort ensured that all users had access to clear and accessible resources, promoting autonomy in using the system.

Fig. 8 – One of the several training sessions conducted with the school managers.

The infrastructure team was responsible for ensuring that the technological architecture was functional and aligned with the project's demands. The activities included from the initial configuration of servers to the continuous monitoring and maintenance of the virtual machines (VMs) that support the system. Among the first actions carried out, the requirements gathering and the configuration of the production environment stood out, including the installation of SUAP and auxiliary servers such as Moodle and OpenProject. This stage involved complex adjustments, such as the configuration of Django servers with Gunicorn and PostgreSQL databases, in addition to the creation and testing of DNS entries for the various services used.

The team focused its efforts on adapting and optimizing the technological environment, performing tasks such as firewall configuration, SSL certificate management for secure system access, and external server monitoring. Furthermore, specific configurations were customized, such as adjustments to the upload capacity of the Moodle training environment and modifications to SUAP to meet institutional needs, including certificate issuance and user permission management. As illustrated in figure 9, it is possible to see one of the pages of the Moodle platform, essential as an asynchronous teaching tool, enabling a flexible learning experience tailored to the users' needs (Archan & Egger, 2023). Regarding technical support, a support channel was created to clarify user questions, solve technical issues, and identify and correct system bugs.

To ensure the continuity of the project and the protection of data, backup systems, redundancy and failure recovery solutions were implemented and new servers were configured, creating a robust and reliable infrastructure, enabling the system to withstand adverse situations.

The implementation of SUAP in the technical schools of the State of Mato Grosso was achieved through the collective efforts of the project teams, representing a milestone in the modernization of administrative and academic management in the state's technical education system. As a centralized platform, SUAP streamlines processes, enhances user experience, and addresses the specific needs of these institutions. With 719 students, 124 technical staff members, 190 teachers, and 800 records of previous courses already registered, the impact and scope of the system are evident (Universidade Federal de Mato Grosso & Núcleo de Tecnologia da Informação (NUTI), 2024). By fostering more efficient management, SUAP directly benefits administrators, teachers, and students, laying a solid foundation for future improvements and expansions in educational infrastructure. As shown in Figure10, the SUAP login screen provides secure access to different users, facilitating

Fig. 9 – Web page of the Moodle platform, where online training and activities were made available for managers and students.

their interaction with the platform.

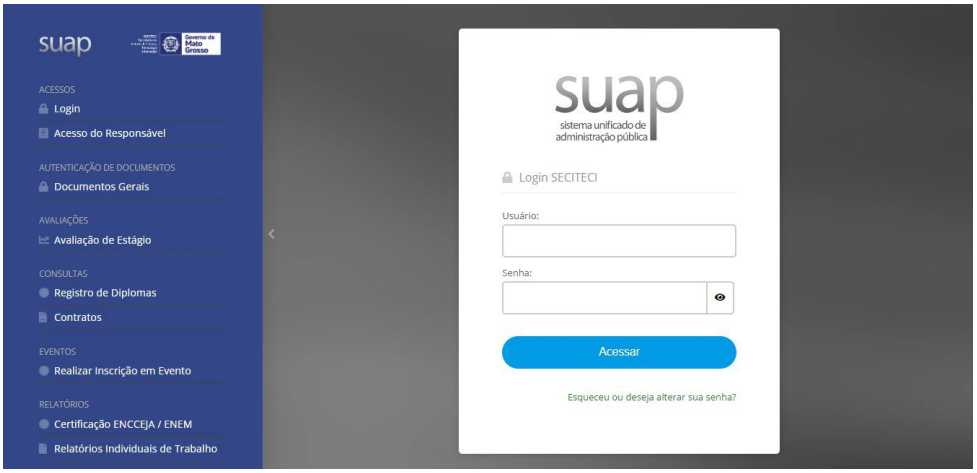

Fig. 10 – Login screen of the SUAP system

Additionally, the homepage (Figure 11) centralizes administrative and academic functions. This initiative reinforces the state's commitment to modernizing public administration, contributing to efficiency and innovation in the educational sector (Governo de Mato Grosso, 2023).

5. Conclusions

The successful implementation of SUAP in the technical schools of Mato Grosso highlights the role of digital government in fostering social cohesion and reducing inequalities through technological innovation in public administration and education. By modernizing administrative processes and integrating digital tools, this initiative has not only enhanced efficiency in school management but also contributed to a more equitable and inclusive education system, particularly in a geographically and socioeconomically diverse state like Mato Grosso.

One of the most significant impacts of this project has been its ability to bridge the digital divide between urban and rural technical schools. Historically, schools in remote areas have faced challenges such as limited administrative support, fragmented student records, and inefficient communication channels. The deployment of SUAP has mitigated these issues by centralizing data, automating processes, and providing digital access to educational and administrative resources, ensuring that all institutions—regardless of their location—operate under the same robust governance framework. This harmonization of school management practices directly

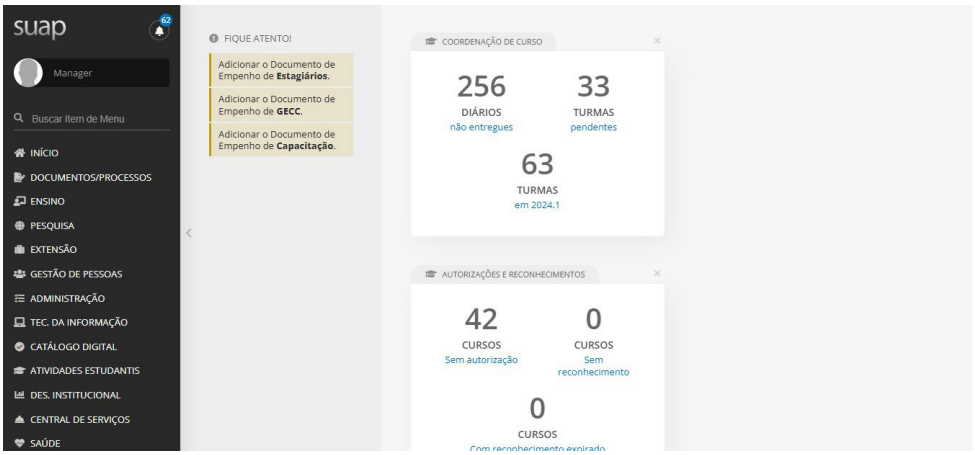

Fig. 11 – Home page of the SUAP system.

contributes to reducing educational disparities and promoting social cohesion by guaranteeing equal access to high-quality institutional support.

Beyond improving internal efficiency, SUAP has also fostered greater transparency and accountability in educational governance, reinforcing public trust in digital government initiatives. The integration of cloud computing, secure authentication mechanisms, and real-time monitoring has enhanced data security and accessibility, empowering both educators and policymakers to make informed decisions. Moreover, by streamlining bureaucratic processes and minimizing administrative inefficiencies, the system has allowed technical schools to focus more on their core mission: providing students with the skills and knowledge necessary for their social and professional development.

This initiative aligns with Mato Grosso's broader Digital Strategic Agenda (2023–2027), which prioritizes digital transformation as a tool to enhance public services, reduce bureaucracy, and foster innovation. The success of the SAEPT project underscores how digital governance can drive institutional modernization, facilitating the delivery of more effective and people-centered services. Furthermore, this case study demonstrates how public sector digitalization can be leveraged not only to optimize workflows but also to create more inclusive policies that address systemic inequalities.

The lessons learned from this project provide a replicable model for other regions seeking to implement digital solutions in education and beyond. Future developments should focus on further expanding SUAP's functionalities, integrating predictive analytics for decision-making, and incorporating adaptive learning tools to support students from diverse backgrounds. Additionally, sustained investment in digital literacy programs for educators and administrators will be essential to ensuring the long-term sustainability and effectiveness of the system.

Ultimately, this project reaffirms the transformative potential of digital government in fostering social cohesion and reducing inequalities in public education. By leveraging technology as a mechanism for inclusion, transparency, and efficiency, SUAP serves as a concrete example of how digital governance can empower communities, strengthen public institutions, and create more equitable educational opportunities. As digital government continues to evolve, initiatives like this will play a crucial role in ensuring that technological advancements serve as a catalyst for social and economic development, reinforcing education as a fundamental pillar of a just and cohesive society.

Abstract. This article analyzes the implementation of the Sistema Gestão Presente, an initiative of NEES (UFAL) in partnership with the Ministry of Education for the interfederative integration of educational data, with the aim of optimizing data management and supporting educational programs at a national level. This study highlights the main challenges faced during the process of implementing this system, using as a repertoire the discussion about data governance, which has already existed in Brazil for some decades. Based on focus groups, one-on-one meetings, discussion groups and experience reports, the article brings together challenges and strategies in four categories: 'Programa Pé-de-Meia business rules challenges', 'Service challenges', 'Follow-up and monitoring challenges' and 'Technological challenges'.

Keywords. data governance, implementation, public policies, education.
Research paper, DOI: https://doi.org/10.59490/dgo.2025.967

1. Introduction

Digitalization has become a strategic priority for many governments around the world, especially about data governance and the implementation of public data management systems. The integration of educational data, in particular, has proved to be a complex but crucial challenge for improving public policies in the education sector. In Brazil, one of the most recent and significant examples of this attempt at digital transformation is the Sistema Gestão Presente, an initiative aimed at the interfederative integration of educational data at a national level. Developed by the Núcleo de Excelência em Tecnologias Sociais (NEES/UFAL) in collaboration with the Ministry of Education (MEC), this system seeks to optimize the management of educational information and subsidize important programs, such as the Programa Pé-de-Meia.

However, implementing such a comprehensive and complex system is no simple task, and various challenges arise along the way. Interfederative integration between states, municipalities and the federal government, which is necessary for the Sistema Gestão Presente to be fully operational, requires harmonization of data, standards and protocols that are often difficult to establish, given the diversity of local realities and the lack

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

of adequate infrastructure in some regions. Furthermore, implementing digital systems in public contexts involves overcoming obstacles related to political, cultural and organizational issues. In this scenario, understanding the challenges faced by subnational governments (states, municipalities and other federative entities) and the strategies adopted to overcome them is fundamental to the success of digital transformation in the education sector.

The aim of this article is to identify the main challenges faced in implementing the Sistema Gestão Presente and to report on the strategies developed to deal with them. Through this case study, which takes on the characteristics of an action research project, the experiences of the different actors involved in the process were analyzed, with an emphasis on the follow-up and monitoring methodologies, meeting local demands, and the specifics of the qualification criteria for the Programa Pé-de-Meia. This study is part of the broader context of digital transformation in the public sector and contributes to understanding the obstacles and solutions applied in the process of educational data governance between the different federal levels of government.

The methodology adopted for the research is mostly qualitative, with a case study of the Sistema Gestão Presente. For data collection, focus groups were used, as well as one-on-one meetings, discussion groups and experience reports from the system users. The data was analyzed using content and discourse analysis techniques, allowing for a deeper understanding of the dynamics involved in implementing the system and the different strategies developed to overcome the challenges identified. The analysis also made it possible to identify lessons learned and good practices that can be applied in similar contexts.

The results obtained show that various strategies have been implemented to ensure the effectiveness of the Sistema Gestão Presente. Data visualization tools were created, such as Business Intelligence (BI) and reports aimed at different actors, with a view to continuous monitoring and follow-up. General and specific training was provided, as well as individualized support according to the needs of each case. In the context of the Programa Pé-de-Meia, specific functionalities were developed, such as the identification of people deprived of their liberty and new functionalities aimed at Youth and Adult Education (Educação de Jovens e Adultos - EJA). Finally, the system now has additional features, such as the ability to activate and inactivate enrolments and send data in .xsl file format, optimizing the management of educational information.

2. Methodology

The fact that this research team also manages the implementation of these policies means that the process of identifying the challenges and defining the strategies to solve them has the characteristics of 'action research'. According to Foster (1971), this is a

> type of applied social research, which differs from other varieties by the immediate involvement of the researcher in the action process and where the intention of the parties is to get involved in the change that comprises the properties of the system itself.

This methodology aims to investigate and solve a problem at the same time, in other words, “it has a dual commitment: to find and implement solutions to problems” (Drago, 1989, p. 66). The action research that led to the reflections and improvements listed in this article is in line with the in itinere evaluation process that management and monitoring coordination carry out during the policy implementation stage. This is the category of evaluation that takes place during implementation and corresponds to monitoring, the purpose of which is to monitor processes and make the necessary adjustments to policies (Secchi, 2015).

Each of the challenges listed in this text (Programa Pé-de-Meia business rules challenges; Follow-up and monitoring challenges; and Technological challenges) had its own techniques for collecting data and identifying problems, as well as methodologies for structuring strategies to solve or mitigate them. In general, the vast majority used qualitative survey techniques, with the exception of the Follow-up and Monitoring Challenges, where qualitative and quantitative data analysis techniques were combined. The table below systematizes the techniques used by each of the fronts:

Fig. 1 - Research techniques used in each of the axes of analysis.

Analytical axis	Mapping the challenges	Definition of strategies
Business rules challenges of the Programa Pé-de-Meia	One-on-one meetings and discussion groups between consultants and operators.	Focus groups, participant observation and discourse analysis of technical reports.

Follow-up and monitoring challenges	Discussion groups with consultants and federal managers, as well as ex-post monitoring of implementation (clustering and analysis of quantitative data).	Discussion groups with federal managers, implementation teams and data scientists and dynamic mapping of user experience of interaction with the tools.
Technological challenges	One-on-one meetings and discussion groups between consultants, operators and federal managers.	Discussion groups between the technological development team, the implementation team and federal managers, followed by technical action to implement improvements to the system.

In the case of the Programa Pé-de-Meia Business Rules Challenges, in typical action-research fashion, data and information were collected during the implementation process by the implementing agents themselves - consultants who have constant contact with the Secretariats during the 15-day data submission window each month. The difficulty was detected through contact with the operators of the networks that offer EJA, in one-on-one meetings and discussion groups held between August 26 and September 13, 2024. To define the strategies for incorporating EJA into the PDM system and business rules, focus groups were held with all the state networks, online, between September 19 and 24, 2024.

The groups were divided so that there were three state networks in each room, with the exception of the state of Rio Grande do Sul, which had to be interviewed individually due to unforeseen circumstances. The rooms were divided as follows: (1) Acre, Paraíba, Goiás; (2) Amapá, Rondônia, Minas Gerais; (3) Rio Grande do Norte, Roraima, Sergipe; (4) Pernambuco, Paraná, Tocantins; (5) São Paulo and Maranhão; (6) Rio Grande do Sul; (7) Alagoas, Pará, Rio de Janeiro; (8) Amazonas, Distrito Federal, Mato Grosso; (9) Ceará, Mato Grosso do Sul and Santa Catarina. Subsequently, a discourse analysis of the meeting minutes, participant observation and a technical report were carried out.

As with the previous challenge, the identification of the Follow-up and Monitoring Challenges comes from the experience of the researcher-authors themselves, who work in and manage the policy implementation process. Therefore, the action-research process itself made it possible to map out these challenges, either through the demands for data received in discussion groups with the implementation consultants and the Federal Managers, or through the in itinere evaluation inherent in the policy cycle. The implementation process itself, therefore, and its actors, raised the need for monitoring, clustering and analysis of the data received by the System. In order to overcome this challenge, discussion groups were held with federal managers, implementation teams and data scientists between October 2024 and February 2025, in addition to mapping the user experience of interacting with the data visualization tools created. The process of creating the tools began in August 2024, and the stages of delivering the monitors and dashboards have already begun, with all the products expected to be delivered by the end of the first half of 2025.

In the case of the Technological Challenges, the process has different characteristics from the others, mainly because it involves direct changes to the system itself. The consultants continued to be key players in mapping the challenges, in addition to the group meetings and technical reports issued. These challenges were identified in individual meetings between the consultants and the networks and in discussion groups with the networks, held daily during the 15-day window for sending data in the month. These moments of collective discussion with the networks take place online, are led by the implementation team and are open to all those who have signed up to the Sistema Gestão Presente.

The demand to improve the system's ability to receive files in .xls format arose during the first data submission window, which took place from April 3 to 12, 2024, but gained momentum during the following window, between May 2 and 10 of the same year. On the other hand, the improvement in viewing multiple enrollments was not directly raised by the Networks, but was observed in the operators' reports to the consultants in the individual meetings and collective discussions of the June (June 1-14, 2024) and July (July 29-August 9, 2024) windows.

The solutions to the problems identified were already clear during their mapping. However, it took an effort on the part of the technological development team to implement these changes in the system. After opening an internal protocol on these demands for improvements, various discussion groups were held between the technological development team, the implementation team and federal managers, leading to technical action to implement improvements to the system. From the detection of the challenge, through the discussion stages, to the system improvements, it took five months of work on each demand.

The methodological procedures used both for mapping the challenges and for defining the strategies reinforce the

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

importance of combining action research and in itinere analysis of the public policy implementation process. Although each of the challenges listed here has its own particularities in terms of the techniques used, all the strategies have a common goal: inducing the use of the system by the adhering Networks and improving the platform's user experience.

3. Data Governance in Brazil

According to ENAP (2019) "the government is an information institution": it consumes information and produces information. "Its performance, in all areas, is linked to this information". From this understanding, and in view of the digital revolution that processes, data and functions have experienced in the last 50 years, trends and changes in previously established management models have emerged. Along these lines, Enap (2022) cites the "New Public Governance" as a model that "seeks to meet the demands of an increasingly complex society from a network approach with various actors to govern" (Enap, 2022, p. 4), and which involves aspects such as the promotion of e-government, the intention of open government and the integrated development of services together with the government.

In this ecosystem, one of the strands linked to NPG is identified as "Digital Age Governance" (DEG) and represents a trend developed from the facilitation of ICTs (Information and Communication Technologies). This strand is characterized by "the incorporation of various political, cultural and institutional systems" (Fraga, 2020). It is in the context of this administrative reform, based on an innovative context such as digital transformation, that new governance practices are being designed and implemented. A major challenge for public institutions in this scenario is not to repeat, in the virtual environment, the shortcomings of physical structures, such as confusing government information that is ill-prepared to meet new social demands (Nogueira Junior, 2019).

Within the scope of the Digital Age Governance (DAG) fronts, a specific approach is being developed for data management in the context of digital transformations, e-government and open government. The term "Data Governance" is used to describe this approach. According to Enap (2019, p. 5),

> in short, Data Governance is responsible for managing the principles of organizing and controlling data and information. This management involves interfacing with various other functions and establishes corporate policies and guidelines for governing data, as well as assigning roles and responsibilities.

Data Governance covers a very broad scope, going beyond simply defining norms and standards, or controlling and allowing access to information. It also involves a more detailed approach to the organization's strategic data, analyzing and designing the processes that produce and consume it. In this vein, Enap (2019, p. 5) further defines Data Governance as the set of policies, processes, people and technologies that have the "objective of improving the efficiency of management processes and data quality, in order to promote operational efficiency, as well as guaranteeing the reliability of information that supports decision-making".

In Brazil, digital government actions began to be structured in the 2000s. With the aim of prioritizing the use of ICTs to democratize access to information, expand popular participation in the construction of public policies and improve the quality and effectiveness of services to citizens, the "Electronic Government" (e-Gov) was built. This project was a milestone in the development of e-government in the country, materialized in the adoption of digital platforms and the availability of public services online, and represented Brazil's accompaniment of international trends in the digitalization of public administration, aligning itself with global initiatives to promote greater transparency, efficiency and digital inclusion.

The development of Data Governance strategies in Brazil by the federal government has become increasingly important in recent years, with the aim of guaranteeing the efficient and secure management of public information. The creation of national policies, such as National Open Data Policy[1] and the Lei Geral de Proteção de Dados Pessoais (LGPD) (National Open Data Policy and the General Data Protection Law)[2], for example, illustrate the commitment to promoting transparency in access to data and guaranteeing the privacy and security of personal information. Figure 2 shows the timeline of actions involving Data Governance in Brazil, within the scope of the Federal Government:

Fig. 2 - Timeline: evolution of Data Governance in Brazil.

2000	2001	2002	2003	2004

[1] A set of guidelines and strategies established by the Brazilian government under Decree No. 8,777 of May 11, 2016, to promote transparency and make public data available in an accessible, structured and open way to the population.

[2] The Lei Geral de Proteção de Dados Pessoais (LGPD) (The General Personal Data Protection Law), Law No. 13,709, was sanctioned on August 14, 2018 and came into force in September 2020. It establishes rules on the collection, storage, use, processing and sharing of personal data in Brazil, with the aim of guaranteeing citizens' rights to privacy and the protection of their personal data.

It is on the path (and in the qualification) of these technologies that the Sistema Gestão Presente emerges. At the same time as establishing government policies and guidelines for collecting and sending educational data at national level, the partnership between NEES and MEC develops and strengthens the management of this data, with the aim of qualifying and guaranteeing the reliability of the information that supports important decision-making. Data interoperability and cross-referencing with other government databases (Gestão Presença,

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

CadÚnico, Receita Federal, Inep, Ideb) are just some of the innovations proposed by the SGP, which has undoubtedly drawn on many lessons learned at the forefront of Data Governance in Brazil.

Interoperability frameworks, digital identity systems and data infrastructure are among the most common key enablers mobilized to promote an environment conducive to the dynamics necessary for the growth of digital government.

The Sistema Gestão Presente

Developed by the Center of Excellence in Social Technologies (NEES/UFAL) for the Ministry of Education, the Sistema Gestão Presente (SGP) is the latest innovation in data governance in Brazil. Recently institutionalized by Mec Ordinance No. 234, of April 2, 2025, the SGP is part of the "MEC Gestão Presente - Basic Education Data Platform", which aims to

> foster and adopt digital government instruments in the management of basic education policy, at federal, state, district and municipal levels, in order to ensure that school information is collected and shared in a standardized and effective manner (BRASIL, 2025).

The formalization of the Sistema Gestão Presente in the Ordinance confirms the commitment in Brazil, mentioned by OECD (2018, p.116), to develop digital government through "legislation that regulates the use of digital technologies in the public sector, the economy and society". The platform gathers data related to education across the country, integrating state, municipal and federal networks, from basic education to higher education. The aim of the system, in addition to becoming a robust database of education in Brazil, is to enable school administrators to monitor the educational trajectory of the students in their networks, support school management and mitigate school dropout.

Currently (as of April 2025), the system receives registration data on students and their legal guardians, as well as data related to school enrollment and attendance. The scope and quantity of data gathered in the SGP also reinforces another major objective of the initiative: the integration of education data with various public policies (federal, state and municipal). In this sense, the SGP aims to simplify the process of sending and receiving education information related to various educational policies.

The implementation of the Sistema Gestão Presente was strategically aligned with the launch and implementation of the Programa Pé-de-Meia, an initiative to encourage the permanence and completion of high school for students enrolled in the public education network, launched by the Ministry of Education in 2024. To guarantee students' access to the incentives, which is directly linked to student attendance data, state and municipal Departments of Education, as well as federal education systems, must send student enrollment information via the SGP. In the Pé-de-Meia module, the platform verifies the student's eligibility to receive the incentives by comparing data sent by the education networks and systems with data from the Ministry of Social Development (MDS) and forwarding the information for account opening and payment to Caixa Econômica Federal (Federal Savings Bank).

In addition to integrating education data (basic and higher education), simplifying the process of sending and receiving information for public policies, and supporting educational and school management, the implementation of the Sistema Gestão Presente facilitates access to information (both by public administration and the general population) and relieves the burden on civil servants of the Departments, who, before the system, had to send the same data to different channels related to the various existing public policies. It is envisioned that, with the SGP, all policies will be "fed" by the same system, avoiding cumulative and disorganized data processes.

4.1. SGP Implementation: Challenges

Implementation is the phase in which the outlined alternatives are executed, transforming laws and guidelines into actions. According to Howlett, Ramesh, and Perl (2013), implementation is the phase of putting previously made decisions into practice, involving the actions of bureaucrats and the use of necessary instruments. The implementation phase is crucial, as the execution of a policy determines its effectiveness. According to Pires (2017), the way implementation occurs can affect individuals' access to public goods and services, impacting the overcoming of social inequalities. However, implementation is complex, interactive, and often uncontrollable, as it needs to adjust to the reality of situations, which can diverge significantly from what was planned (LOTTA, 2019).

To implement the Sistema Gestão Presente, the greatest need is data. How can all educational networks in Brazil be induced to send data on their high school students? To this end, a combination of strategies was designed by the public policy management of NEES, in dialogue with the Ministry of Education. The benefit granted by the Programa Pé-de-Meia undoubtedly already induces a large part of the networks to send information. But what processes are carried out for this sending? How is the sending done? By whom is the sending done?

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

The school networks (municipal, state and federal) appoint up to five employees who will be responsible for sending the data to the Sistema Gestão Presente. They are called “operators”. These professionals will be registered on the Simec[3] portal and, consequently, the SGP development team will add them to the system's users. Operators will enter the platform using their login already used in the Gov.br system[4]. With this access, the operator will be able to send data, monitor the processing of this data, check the status of enrollments and students eligible for the Programa Pé-de-Meia.

Taking advantage of the dialogue with the Programa Pé-de-Meia - which is based on students' monthly attendance - the Sistema Gestão Presente receives monthly data from the education networks. For approximately 15 days of each month, the system is “open” for receiving student data: from student registration, enrollment, attendance, transfers and completion. The data sent in during these 15 days will be processed in the remaining 15 days of the monthly cycle and will release student payments. The Sistema Gestão Presente receives data in two ways: by spreadsheet and by API. The strategy is to be able to cover departments with different structures and technologies and, at the same time, make the operator's job as easy as possible.

In order to cover the diversity of secretariats and make the operator's job easier, assistance and support strategies have been developed within the scope of the Sistema Gestão Presente. The main ones are the team of consultants, the training schedule and the support materials. The team of consultants was designed to support the networks and provide more personalized support, with a close eye on the realities and needs of each one. These consultants have been divided by region and state and are on call to answer questions and guide public managers and operators during the 15-day “data submission window”, but remain available for the rest of the month.

These same consultants are responsible for conducting training and on-call sessions for operators during the data submission window. The training sessions offered cover all the data submission processes in the Sistema Gestão Presente (registration, submission of frequencies and reporting of transfers and conclusions), for the two submission formats (spreadsheet and API) and the business rules of the Programa Pé-de-Meia (general rules, eligibility and payment). During these moments, the step-by-step processes are presented and the main doubts about each one are listed. In addition to this, there are also moments specifically for “questions and answers”, where any questions the operators may have been answered.

A series of support materials on the SGP was developed to provide support to operators outside of the training and on-call sessions and to concentrate the consultants' demands on the most complex cases. The most complete and requested material is the “Sistema Gestão Presente Manual”. This document details every step-by-step involved in each of the system's processes, listing the most frequently asked questions and pointing out exceptions and points of attention. The material, made available in PDF format to all operators, also provides various other secondary materials, such as screen recording videos of the processes and guides for filling in each column of the spreadsheets that are received in the System.

Even if various strategies are developed, both in terms of policy design and implementation, there will always be unexpected situations and challenges along the way. In the case of the Sistema Gestão Presente, this was no different. Although various processes, plans and procedures were created to facilitate its implementation, a number of challenges were faced in its first cycle of operation. The next section will deal specifically with these challenges, listing the solutions developed to overcome each one.

4.2 Challenges Faced

Brazil is a federative republic made up of three levels of government: municipal, state and federal. Federative units have the organizational autonomy to manage available resources and establish efficient processes and routines, develop strategies and implement policies according to the local reality. As a result of this autonomy, the lack of a unified education system in Brazil represents a major challenge, as each school network has the autonomy to organize itself pedagogically and administratively. Along these lines, the OECD (2019) has already mentioned the importance, for the coherent and sustainable implementation of digital government policies, of “coordinated public sector efforts across all sectors and levels of government”. But this autonomy, which is essential for dealing with the diverse educational and administrative realities of different contexts, can represent a challenge when implementing educational policies at national level.

The challenges encountered in implementing the Sistema Gestão Presente (SGP) were classified into four main categories to facilitate their analysis and understanding. These are: 'Programa Pé-de-Meia business rules challenges', 'Service challenges', 'Follow-up and monitoring challenges' and 'Technological challenges'. The first

[3] Simec is the Integrated System for Monitoring, Execution, and Control of the Ministry of Education (MEC), a platform that monitors and manages the federal government's budget and proposals in the area of education.

refers to the adaptations and strategies developed to adapt the Sistema Gestão Presente to particularities that arose during the implementation of the Programa Pé-de-Meia, and which helped to qualify the data on the platform. The second category, 'Service challenges', covers difficulties related to communication and technical training of the system's data operators and the activities developed to overcome them. As part of the follow-up and monitoring challenges, the tools developed for controlling and analyzing the data received by the system are described, as well as the relevance of this process for implementing the policy. The last category lists some of the challenges experienced by the systems development team in inducing the use of the SGP and the interaction of users (operators) with the platform, and the improvements implemented to address them.

4.3 Business Rules Challenges for the Programa Pé-de-Meia

During the process of implementing public policy, it is expected that some unexpected situations will lead to its redesign, to adapt to different contexts. In this sense, the initial linking of the implementation of the Sistema Gestão Presente to the Programa Pé-de-Meia helped to qualify the collection of student, enrollment and educational institution data. The strategies developed aim to deal with the challenge of covering the diversity of high school scenarios and offers in Brazil. To illustrate this point, we mention one of the situations we have experienced, which is linked to changes in the business rules of the Programa Pé-de-Meia and data collection in the Sistema Gestão Presente: the inclusion of Education for Young People and Adults (EJA)[5].

The inclusion of the "Education for Young People and Adults" (EJA) teaching modality in the Programa Pé-de-Meia panorama of beneficiaries led to the need to redesign the business rules of both the Program and the SGP. In the case of the SGP (our focus in this text), it was necessary to create strategies that encompassed (and did not harm their respective students) the various forms of offer and modality of EJA (face-to-face, semi-presential and non-presential offer). The modalities of provision directly affect the calculation of student attendance, as several educational institutions did not even collect student attendance data, and in others, attendance was only collected at a face-to-face meeting offered every one or two months.

In order to take account of these realities and ensure that EJA students were not disadvantaged by them (or that those eligible to receive the benefit stopped receiving it), a change was made to the attendance calculation carried out by the Sistema Gestão Presente, which now takes into account the workload offered by the educational institution. The formula used by the SGP to calculate the student's monthly attendance percentage is now: Present workload/Offered workload *100. This means that the student's attendance percentage will only be calculated taking into account the hours offered to them by the educational institution.

In addition to this, another particularity of the EJA that has led to changes in the Sistema Gestão Presente (both in data collection and management) involves the timing and duration of each stage/cycle in relation to regular high school. There are educational institutions where the complete EJA cycle (which corresponds to full secondary education) lasts six months, others a year, others a year and a half... With these cases in mind and the importance of collecting this data, a field was inserted to identify the total workload planned for the course in which the student is enrolled. Containing the options "First third of the workload of the EJA offer"; "Second third of the workload of the EJA offer" and "Third third of the workload of the EJA offer", this field helps to estimate which stage of secondary school the student is in.

In this way, the changes implemented in the Sistema Gestão Presente highlight the difficulties and adaptation needs that a platform that sets out to encompass all Brazilian education data goes through during its implementation period. By restructuring parameters such as the calculation of attendance and the identification of the stage taken, the system is molded to the particularities of this modality, guaranteeing greater precision in the collection and interpretation of data.

4.4 Follow-up and Monitoring Challenges

In order for us to identify the challenges and consequently plan actions to overcome them, the process as a whole needs to be monitored and followed up. In this sense, how can we design monitoring strategies in a policy that is constantly in flux, both in terms of actions and players? How can we identify the main difficulties and errors in sending data, beyond the operators' reports (even because of the difficulty in contacting some of them)?

Monitoring is an essential activity that supports decision-making, involving production, recording, monitoring and critical analysis of information, with a view to effective management and continuous improvement of the services offered to the population (Jannuzzi, 2013). On this path, the greatest (and most complex) thermometer of the assertiveness of the implementation is obtained through data: in this case, data that indicates the sending of information by operators. In the first few months of implementation, we began to develop incipient

[5] Mode of education established by Law nº 9,394/96 (Law of Directives and Bases of National Education), aimed at individuals who did not have access to or continuity of studies in elementary and high school at the appropriate age.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

tools for monitoring the sending of data, which provided information on frequencies sent by Network (state, municipal and federal). This is the basic concept for monitoring the success (and critical cases) of the implementation of the Sistema Gestão Presente, as it shows how easy or difficult it is to operate the platform and send the data it requires.

Using this data (frequency sending), it is possible to identify, in a basic and general way, which networks have already sent a high percentage of data in relation to the number of students enrolled, and those that have not sent or have sent a quantity of frequencies that represent a low percentage in relation to the whole network. Since the first months of the SGP's implementation, during the data submission windows, this daily monitoring of submissions has been carried out, which, through the figures, directs the consultants' work to the most critical cases (networks that have submitted a low percentage of data).

As the process in the system became more complex (more functions and procedures) and the data provided by the networks increased (student profile data, characteristics of the modality offered), both the consultants and the implementation coordinator felt the need to improve monitoring of the induction to use the SGP and, consequently, to send data to the system. In order to qualify this monitoring, various strategies were developed, with the different actors who demand data from the system in mind. In general, the strategies involved monitoring panels, BIs (Business Intelligence)[6] and reports.

The strategies developed can be categorized by monthly period (during the data submission window and after the window closes) and by the actors they are aimed at (consultants, implementation managers and coordinators and Ministry of Education managers). For this analysis, we will use the monthly period criterion to describe the initiatives, as illustrated in Figure 4:

Fig. 3 - Data monitoring strategies and tools developed.

Monthly period	Strategy	Target audience
Monitoring during the data submission window (15 days per month)	Daily monitoring bulletins for data sent by the Network (2 to 3 bulletins/day)	Consultants
	Data visualization tool (BI) to monitor the sending of data from the window (hourly update)	SGP and PDM managers and coordinators and MEC managers
Monitoring after the data sending window has closed	Report consolidating data from the closed window	MEC managers
	Sistema Gestão Presente data visualization tool (updates after the data submission window closes)	Managers and coordinators SGP and managers MEC

Source: prepared by the authors

As can be seen in the figure above, different strategies have been developed, each geared towards a specific demand and target audience. The daily monitoring bulletins are an essential tool for the data submission windows, as they allow consultants to keep track of the networks they are responsible for and to prioritize critical cases, identifying those with low submission rates.

In addition to this short daily summary, a visualization tool was developed for SGP managers and coordinators and MEC managers, with the aim of monitoring in “real time” (with one hour of processing). This tool brings together more qualified data on enrollments and students (active, registered and valid enrollments, enrollments per student and reclassifications and transfers) and attendance (lack of attendance information by state and daily evolution of attendance sent by administrative dependency). The data presented in the tool allows for a more in-depth analysis of critical cases and the networks that need to be activated during the window.

Strategies were also developed for monitoring consolidated data after the end of the sending periods. The tool created for monitoring the Sistema Gestão Presente by managers gathers a larger and more qualified amount of data compared to the tool for monitoring data sent during the window. In this panel, it is possible to check, in addition to student registration data, consolidated attendance and profile data for students registered in the SGP. In the case of attendance, it is possible to view the information sent by month, average attendance by state, evolution and number of attendances above 80% and below 80% and unreported attendance. On the student

[6] BI (Business Intelligence) is a set of tools and technologies used to collect, analyze, and transform data into actionable information, helping managers make more informed strategic decisions.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

profile screen, you can view information by gender, color/race and disability, as well as the number of students enrolled in regular or EJA modalities. All the data visualization tools also have filters that can be applied to all the indicators displayed on the screen: administrative dependency, UF, municipality, modality, reference month, teaching stage and organizational unit.

The last monitoring product strategically developed, this time just to provide the Ministry of Education's management with information, was the consolidated window reports. These materials, as the name suggests, compile the results of the main indicators collected during each submission period in the Sistema Gestão Presente, as well as giving feedback on the actions that were carried out in the implementation and induction axis during the window. This material also presents the critical cases - networks with the least amount of data submitted. As well as reinforcing the importance and results of the policy's implementation work, the reports support decision-making and the creation of new strategies by the MEC.

The development of these strategic products, which are widely used by their target audiences, reiterates the importance of monitoring and following up the implementation of public policies, whatever they may be, so that routes can be recalculated and results can be even more assertive. In the case of the Sistema Gestão Presente, these products are essential for qualifying the data collected and improving the data collection process itself.

4.5 Technological challenges

Many of the changes to business rules, as well as difficulties reported by operators to service consultants, lead to changes in the Sistema Gestão Presente - as well as adjustments to support documents linked to the system, such as the spreadsheets used to send data. In most cases, these changes are linked to three challenges: adapting to the different Brazilian educational contexts, the technical knowledge of the operators and improving the experience of the system's users.

To illustrate these changes, we have selected some (of the many) implemented in the 2024 cycle, focusing on improvements to the user experience, also related to the different levels of technical knowledge reported by the operators of the Education Networks. We won't go into the changes to the fields in the spreadsheets, which are the tools used to send the data (by those who don't use the API), and which are linked to changes in the business rules of the policies and their adaptation to the various high school offers in Brazil. Some of the adjustments involve the inclusion of fields to identify students in deprivation of liberty (PPL) and social name information.

The focus of this section, therefore, is on the strategies developed to deal with “everyday” challenges, which may often seem “small” - but which, when it comes to the amount of data sent by each network, can lead to major problems and, consequently, result in the disqualification of data, the lack of data and even the loss of benefits for students eligible for the Programa Pé-de-Meia. Against this backdrop, we will briefly describe two adjustments that were implemented with a focus on inducing use of the system and improving the user experience in the SGP: expanding the accepted spreadsheet file format and visualizing multiple enrollments. It is important to note that each of the changes to the system generated specific training for operators, in order to describe and demonstrate the step-by-step process and resolve doubts.

One of the biggest challenges for operators when sending data was handling the pre-formatted spreadsheets for this process. Their templates (“blank”) were downloaded directly by the system in .csv[7] format, and it only accepted uploads of files in the same format. Many operators reported difficulties in using this type of document and, in August 2024, it was implemented that spreadsheets could also be uploaded in .xls (the most common file format in Microsoft Excel programs). This change, which may be “simple” for those reading this description, was extremely important for the networks, as well as for encouraging the use of the system and broadening and facilitating the sending of data.

The second improvement developed within the scope of the Sistema Gestão Presente, with a focus on supporting its use and qualifying the data, was the ability to view students with multiple registrations, followed by the possibility of activating and inactivating registrations directly in the SGP. The SGP's data management flow faced a challenge not previously foreseen (or at least not to this extent): student transfers between different educational institutions. It is relatively common for students to transfer from one school to another during the school year, for any number of reasons.

This is another “commonplace” situation that has brought challenges for the SGP. In order for a student's transfer process to be consolidated, it is necessary for (I) the school of destination to enroll the student from the date they entered the institution and (II) the school of departure to report the transfer between institutions, based on the spreadsheets that are sent to the system. This process, however, presents mismatches and, in several cases, the student has two (or more) active enrollments in the Sistema Gestão Presente. At the start of implementation,

[7] CSV (Comma Separated Values) is a type of text file used to store data in a structured table format, separating the values with commas. These files can be created and edited in various programs, such as: Microsoft Excel, LibreOffice Calc, OpenOffice Calc, Google Sheets.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

viewing and correcting these duplicate registrations was only done via spreadsheets (by downloading and sending documents).

To help in the induction of the system, make the work of the operators less complex and more practical and mitigate the cases of multiple registrations in the SGP, new functionalities were designed, developed and implemented on the platform. In general, with this improvement, operators are able to check, directly on the front-end, which students have multiple registrations, as well as view the other institutions in which the student is enrolled.

In addition to this, another new feature has been incorporated into the SGP regarding the scope of multiple enrollments. In addition to viewing the information relating to their multiple enrollments, operators can now confirm or inactivate the enrollment directly on the front-end. Those responsible for interaction with the system on the part of the Networks can also check whether the other Network to which the enrollment is linked has also confirmed the existence and permanence of that enrollment in their Network. The two functions, which are accessed in a "Multiple enrollments" section in the SGP, are interconnected and allow the operator to review the enrollments linked to a student (CPF) and inactivate or confirm this information.

To conclude, the changes made are mainly aimed at inducing more efficient use of the Sistema Gestão Presente and improving the user experience, considering the daily challenges faced by operators. Adjustments such as expanding the accepted file format and displaying multiple enrollments are examples of how the changes seek to simplify the data entry process and make it easier to navigate the system. These adjustments, although they may seem simple at first glance, are of great importance in practice, as they have a direct impact on the quality of the data sent by the education networks and on compliance with the program's requirements. Ultimately, these changes are essential to ensure that the system is adapted to different educational contexts and to improve the effectiveness of student data management.

4. Conclusions

The implementation of the Sistema Gestão Presente, focused on integrating educational data between different levels of government, reinforces the Federal Government's commitment to the Estratégia Federal de Governo Digital (EFGD), which promotes the acceleration of the government's digital transformation, and consolidates the vision of a government that is "innovative and collaborative in its efforts to promote the digitalization of its economy and society" (OCDE, 2018, p.38). The initiative aims, among other things, to subsidize public policies aimed at educational inclusion, such as the Programa Pé-de-Meia, and to provide greater efficiency in the management of educational data at a national level. However, as has been identified throughout this study, the implementation of digital systems in a public context faces multifaceted challenges.

During the process of implementing the Sistema Gestão Presente, strategies to mitigate these challenges were designed and adopted. These strategies have a direct link to the concept of data governance, which involves creating effective practices, policies and processes to guarantee the integrity, transparency, accessibility and security of information within a public system. Data governance is a central element for the effectiveness of any information management system, especially when it involves integration between different levels of government. Through visualization tools, specific functionalities and service strategies, the Sistema Gestão Presente is moving towards more efficient data governance, which ensures that educational data is used strategically and transparently to formulate public policies. However, data governance is not limited to implementing technologies; it also requires strengthening institutional capacities and building a culture of collaboration and trust between the different actors involved. The ability to deal with the complexities of data in a government environment requires not only technological innovations, but also a deep understanding of local political and social dynamics.

Throughout the implementation, it was possible to see that the Sistema Gestão Presente, although challenging, can serve as a model for other digital transformation initiatives in the public sector, especially about data integration between different levels of government. The strategies of monitoring, personalized service and adaptation to local needs offer important lessons on how to overcome obstacles related to the decentralization of management and the diversity of realities in Brazil. The experience with the SGP also highlights the importance of continuous monitoring and effective communication between the different actors involved, from technical teams to managers and decision-makers. Ongoing training and personalized support, such as general and specific training, are key to ensuring the system's long-term effectiveness.

However, the successful implementation of the Sistema Gestão Presente depends on constant evaluation and adaptation. Although it has been possible to overcome a number of challenges, the evolution of the system and the improvement of data governance require a continuous commitment to innovation and the improvement of information management practices. The role of technology in the digital transformation of the public sector is undeniable, but it must be borne in mind that the real transformation takes place to a large extent through the integration of technology and public policies. OCDE (2018, p. 48) also reinforced the convergence between

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

technology and public policies, analyzing the Brazilian scenario: “The Brazilian programmes on e-government and digital government reflect the country's path, its main priorities and goals in different periods, and most of all, it shows Brazil's progressive policy consolidation and growing maturity in addressing key issues associated with the digitalization of the public sector”.

In the case of the Sistema Gestão Presente, this integration implies careful data management, which takes into account local specificities, information security and, above all, the social impact of the policies implemented.

Abstract. In the context of increasing demands for efficient and equitable public service delivery, digital transformation has become essential for local governments, particularly within federations marked by inequality. This study investigates the factors driving digital transformation in Brazilian municipalities—a country with significant regional disparities and varying administrative capacities. The objective is to identify which economic and technical-administrative variables influence the digital maturity of local governments. Using data from 4,265 municipalities collected in 2023, the study constructs a Digital Transformation Index encompassing technological infrastructure and digital service provision. Multiple linear regression models assess the relationship between digital transformation and variables such as fiscal autonomy, IT expenditures, bureaucratic quality, and mayors' educational profiles. Results indicate that municipal revenue generation and IT spending positively correlate with digital transformation, while reliance on intergovernmental transfers is negatively associated. Additionally, better-educated civil servants and mayors are more likely to lead digitally advanced municipalities. However, when accounting for regional and population size controls, many of these associations lose statistical significance, underscoring the role of broader structural disparities. The findings suggest that economic and human resource capacity are important but insufficient alone; a more coordinated national strategy is necessary to reduce regional inequalities and support local digital transformation.

1. Introduction

Given the increasing complexity of public problems and the evolving expectations of citizens, digital transformation is not merely an option but a necessity for local governments to ensure equitable access to essential services, improve responsiveness and accountability, and ultimately enhance public value in addressing critical societal challenges. In this sense, local governments worldwide are implementing new digital technologies in different policy domains and functions and conducting digital transformation processes (Branderhorst & Ruijer, 2024; Criado & Gil-Garcia, 2019). These new technologies are changing the landscape of public management and local authorities' abilities to create public value and deliver public services (Filgueiras et al., 2019; Mergel et al., 2019).

Digital transformation in the public sector means new ways of working with stakeholders, building new service

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

delivery frameworks and creating new relationships (Mergel et al., 2019). The focus of digital transformation shifted from internal processes and efficiency gains (e-government) to citizen-driven services, placing the citizen at the center. Adopting new technologies in governments occurs in the context of incremental changes controlled by bureaucratic agents within institutions (Filgueiras et al., 2019; Haug et al., 2024).

Regarding studies on digital transformation in local governments, literature already has important findings. Hong et al. (2022) pointed out that innovation in local governments in South Korea is driven by demand, in which public organizations respond to the needs of citizens. In addition, the study highlighted that electoral incentives motivate local governments to innovate digitally to meet local priorities, that isomorphic pressures matter, i.e., local governments tend to imitate innovative practices of neighbors, and that younger policymakers are more active in innovation. Epstein (2022), when analyzing North American cities, evaluated that the adoption of e-government services between 2014 and 2019 was different, specifically, while earlier adoption was largely driven by larger cities with more resources, by 2019, there was a broader diffusion of e-government across cities of varying sizes. The study found that over time, factors such as population size and broadband access remained significant, but economic variables like municipal wealth lost explanatory power, suggesting that access and infrastructure became more critical than fiscal capacity in determining digital service provision (Epstein, 2022). B. Fan and Pan (2023) analyzed the drivers for Chinese local government strategies and examined the effect of the interaction between IT infrastructure and other organizational resources (financial and human) on e-government performance. The authors found that the interaction between IT infrastructure and financial resources has a positive effect on e-government, while the interaction between IT infrastructure and human resources has a negative effect on e-government performance. Furthermore, they concluded that the effect of the interaction between IT infrastructure and organizational resources (financial and human) on e-government performance increases with decreasing environmental turbulence and increasing environmental complexity.

Moreover, Mergel et al. (2019) and Wilson and Mergel (2022) have pushed researchers to look at digital transformation's social, economic and political aspects from their qualitative research. Mergel et al. (2019) pointed out that external factors and pressures are the main drivers of digital transformation in governments rather than internal factors. Much work has been dedicated to understanding the drivers of digital transformation in local governments worldwide (Epstein, 2022; B. Fan & Pan, 2023; Hong et al., 2022; Mergel et al., 2019; Wilson & Mergel, 2022). Thus, there are indications that the quality of bureaucracies, external demands on government and financial resources are correlated with the process. However, only some studies examined Latin America's context in the digital transformation process (Aguerre & Bonina, 2024; Filgueiras et al., 2019). In this case, we identified a gap in the literature, given that few studies aimed to understand the drivers of digital transformation in Latin American local governments. This article addresses the following research question: What are the drivers of digital transformation in Brazilian municipalities? To address this question, this study aims to analyze the economic and technical-administrative factors associated with digital transformation in Brazilian municipalities, identifying which local government characteristics most significantly influence the adoption of digital technologies and services. Thus, we aim to identify which municipal characteristics are associated with the digital transformation process.

Brazil offers a compelling case study for digital transformation research due to its vast and diverse population within a complex federal system, which provides a rich context for observing the phenomena across different levels and allows the examination of the opportunities and challenges of digital transformation implementing initiatives. The complexities of a federal country stem from deep regional inequalities, fiscal dependencies, and varying administrative capacities across municipalities, creating significant challenges for implementing coherent public policies, especially in digital transformation (Alves & Araujo, 2024; Filgueiras et al., 2019; Grin & Abrucio, 2021; Marenco & Cate, 2021) While existing research has primarily focused on the national level (Filgueiras et al., 2019), this study delves into the experiences of local governments by examining local-level challenges and successes, filling a crucial gap in the literature, so this research contributes to understanding the factors driving digital governance in this complex federal system. This study examines the factors driving digital transformation in local governments in Brazil, considering the technical, administrative and financial inequalities between municipalities.

This paper is divided into four sections in addition to the introduction. The second section provides a background and defines the hypotheses, introducing key concepts related to digital transformation in Brazil. The third details the methodology, focusing on data selection and analysis techniques. The fourth presents the results and discussion, aiming to answer the research question and objective by clarifying the drivers of digital transformation in Brazilian municipalities. Finally, the conclusion restates the main findings, acknowledges some limitations, and offers recommendations for future research.

2. Background and Hypothesis' Definition

Brazil began with e-government initiatives in the 1960s by creating SERPRO (public data processing company) in 1964 (Filgueiras et al., 2019), and in the 1970s, another public data processing company was instituted named Dataprev, initially dedicated to the social security sector. Throughout the 1990s and 2000s, incremental progress focused on digitizing administrative processes and routines. From 2016 onwards, there was a significant

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

institutional change driven by two main factors: (1) the need to respond to the fiscal crisis with greater efficiency and cost reduction, and (2) the influence of the OECD, which advised Brazil with guidelines, case studies and standards to adopt digital transformation policies (Filgueiras et al., 2019). This process culminated in the transition to more comprehensive digital governance based on new norms and paradigms focused on providing services in a federal government platform (GOV.BR) created in 2019.

Despite Brazilian e-government initiatives, research conducted by Przeybilovicz et al. (2018) using 2014 data revealed that most municipalities had limited online services. For instance, over 90% of municipalities lacked online options for obtaining permits, enrolling children in school, or scheduling medical appointments. Furthermore, municipal websites primarily served as information portals. This scenario indicates that, a decade ago, local Brazilian governments' widespread adoption of e-government services was still a significant challenge. The Southeast/South region appeared to be the most advanced in e-government initiatives; conversely, the North and Northeast regions represented the most challenging areas for e-government implementation, revealing a significant disparity in ICT infrastructure and use, poverty, and limited access to technology. These factors hinder the development and adoption of online government services, leaving many of the population underserved (Przeybilovicz et al., 2018).

Internationally, the discussion about government as a platform began at the end of the 2000 decade (O'Reilly, 2011). Since then, a new conception of government and its role in society has emerged and changed over the last few decades. While influential in recent decades, the New Public Management (NPM) paradigm has been criticized for its limitations. Osborne et al. (2013) argued that NPM's focus on internal processes and the application of manufacturing-based theories inadequately addresses the unique characteristics of public services. Instead, they advocated for a "public service-dominant" approach. This approach emphasizes the service-oriented nature of public services, prioritizing citizen co-production, strategic orientation, marketing, and operational management. By recognizing citizens as active participants in service delivery, this approach seeks to provide a more relevant framework for contemporary public management challenges.

A crucial aspect of this revised approach is recognizing the inter-organizational nature of public service delivery. Osborne et al. (2013) highlighted the critical role of coordination and collaboration among organizations involved in service provision. This insight becomes particularly relevant in the context of digital transformation. The successful integration of ICT in the public sector hinges on overcoming significant challenges, including the technical capacity to implement ICT, the perceptions of public managers regarding transparency, efficacy, and accountability, and the persistence of data silos within public administration. These silos, exacerbated by a lack of coordination and limited political-institutional capacity for change (Wilson & Mergel, 2022), hinder the effective digital transformation of public services. As Filgueiras et al. (2019) emphasized, digital transformation necessitates robust policy coordination among various organizations to ensure coherent service delivery aligned with the priorities and objectives of each entity. This requires effective negotiation and agreement among agencies that often operate autonomously, thereby emphasizing the importance of inter-organizational collaboration for successful digital transformation in the public sector.

Given the extensive territorial inequality in Brazil, in other words, uneven distribution of resources, infrastructure, public services, and development opportunities across the country's different geographic regions and municipalities, some municipalities (mainly state capitals and large regional centers) have a greater administrative capacity linked to local government, more significant funding, and more pressure from society to digitize services. Meanwhile, most Brazilian municipalities are small (less than 20,000 inhabitants), and incorporating ICT tools has historically lagged behind (Przeybilovicz et al., 2018). Therefore, the provision of services offered by local governments via the platform is challenged, given the existing heterogeneities. In this sense, given the recent induction of the Brazilian federal government through Decree nº 12.069/2024 to the process of digital transformation of subnational entities (Brazil, 2024), one wonders what can explain the fact that some municipalities have adopted tools to offer services via the platform while others have not?

Thus, this study analyzes the relationship between the economic (H_1, H_2 and H_3) and technical-administrative (H_4 and H_5) dimensions of digital transformation in local governments in Brazil. The hypotheses underlying this research and its rationale are outlined as follows.

2.1 Fiscal autonomy and digital transformation

B. Fan and Pan (2023) argued that the interaction between IT infrastructure and organizational resources, mainly financial and human resources, significantly impacts e-government performance, specifically that financial resources positively enhance the effect of IT infrastructure. In the Brazilian case, local governments' tax revenue collection depends on the current economic structure. By law, the central and state governments transfer a fixed portion of resources to local governments (Alves & Araujo, 2024). Most of these allocations are restricted to designated purposes such as health services, education, etc., limiting their availability for digital transformation initiatives. Therefore, municipalities with thriving economic activity can collect more resources and become less dependent on state and Union

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

transfers but, for the most part, have fewer opportunities to expand the tax base. Based on it and B. Fan and Pan's (2023) proposition, it can be argued that the municipality's fiscal autonomy can affect its digital transformation capacity, taking to the first hypothesis:

H_1. Municipalities with greater fiscal autonomy from federal and state transfers exhibit higher levels of digital transformation.

2.2 Budget expenditures and digital transformation

Budget expenditures provide a key indicator of the financial resources dedicated to e-government initiatives, covering areas such as IT infrastructure, personnel training, and cybersecurity (Z. Fan et al., 2020; Reddick, 2006). The development and upkeep of such infrastructure demand significant financial resources (B. Fan & Pan, 2023; Z. Fan et al., 2020; Salim et al., 2022), inadequate funding can hinder the ability to address technical challenges, upgrade systems, and respond to evolving digital needs (Z. Fan et al., 2020; Osah & Pade-Khene, 2020; Stier, 2015). Governments may struggle to deliver efficient and effective public services without sufficient investment (Welch & Feeney, 2014). In Brazil, municipalities are responsible for financing a wide range of public policies, such as basic health care, education, and social assistance, among others. Investment in technology and digital transformation is one of the priorities that municipalities already need to address. Furthermore, more resources can be required to constrain the capacity to attract and retain skilled IT professionals, which is essential for ensuring the smooth operation of e-government systems.

In other words, governments can allocate substantial funds towards IT investments by generating adequate revenue. This enables them to embrace innovative technologies, expand the scope of e-government services, and improve overall service delivery (Z. Fan et al., 2020; Osah & Pade-Khene, 2020; Reddick, 2006; Stier, 2015). Increased financial resources empower governments to explore new opportunities, such as developing sophisticated data analytics capabilities and implementing advanced cybersecurity measures (Mukhopadhyay et al., 2019). Moreover, sufficient funding can facilitate the training and development of public servants, enhancing their digital literacy and capacity to leverage technology effectively (B. Fan & Pan, 2023). Ultimately, revenue generation empowers governments to create a more responsive, efficient, and citizen-centric e-government ecosystem. In this context, we present the second hypothesis:

H_2. Municipalities with higher revenue generation demonstrate greater levels of digital transformation.

2.3 IT expenditures and digital transformation

The successful implementation and maintenance of e-government initiatives rely on robust IT infrastructure (B. Fan & Pan, 2023); it provides the essential technological backbone that enables governments to deliver efficient and accessible public services. Regarding the technological dimension, IT infrastructure or technological capacity is a significant predictor of e-government service provision (Savoldelli et al., 2014; Welch & Feeney, 2014).

By investing in IT infrastructure, municipalities can streamline processes, reduce administrative costs, and enhance transparency and accountability (Hilhorst et al., 2022; Scholta et al., 2019). A well-developed IT infrastructure facilitates the integration of various government systems, enabling seamless data sharing and collaboration (Janssen et al., 2009). This, in turn, improves decision-making and allows for more informed policy development.

Investing in IT infrastructure empowers municipalities to embrace technological advancements and innovate in service delivery (Z. Fan et al., 2023). By adopting emerging technologies like artificial intelligence, machine learning, and blockchain, governments can automate tasks, improve service quality, and enhance citizen experiences. A strong IT infrastructure also enables municipalities to adapt to changing circumstances, such as natural disasters or economic crises. By leveraging digital tools, governments can respond quickly and effectively to challenges, ensuring business continuity and maintaining essential services (Z. Fan et al., 2023). It takes us to the following hypothesis:

H_3. Municipalities with higher IT expenditures exhibit greater levels of digital transformation.

2.4 Local government bureaucracies and digital transformation

From a Weberian perspective, we can argue that municipalities with higher bureaucratic quality – measured by the level of formal schooling of municipal bureaucrats (Grin & Abrucio, 2021; Marenco & Cate, 2021; Segatto et al., 2022) – are more likely to implement digital transformation initiatives successfully. A well-structured and efficient bureaucracy provides a solid foundation for technological advancements. By streamlining processes, improving communication, and fostering innovation, bureaucratic quality enables organizations to effectively leverage technology to enhance service delivery, citizen engagement, and overall operational efficiency.

Well-educated and well-trained public servants are essential for effective digital transformation; beyond technical skills,

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

they bring analytical and problem-solving abilities needed to integrate new technologies into public services (Mergel et al., 2019; Zhu & Zhang, 2019). Continuous training keeps staff updated on evolving tools, data protection laws, and cybersecurity (Hilhorst et al., 2022). Additionally, trained bureaucrats increasingly take on roles like digital service designers, driving innovation (Melin et al., 2024). These "digital champions" help overcome internal resistance and improve project implementation (Wilson & Mergel, 2022) while their expertise reduces errors and builds citizen trust (B. Fan & Pan, 2023).The quality of the bureaucracy in the subnational context and its role in conducting public policies (including digital transformation) has been explored in Brazil and internationally (Grin & Abrucio, 2021; Melin et al., 2024). Despite the challenges in its measurement due to multiple factors, in Brazil, the Brazilian Institute of Geography and Statistics (IBGE) periodically collects information on the professional qualifications of bureaucrats in local governments. Following IBGE's proposition, years of formal study will be the proxy to measure the quality of bureaucracy.

We hypothesize that a strong workforce with expertise and training is essential for designing, implementing, and maintaining digital solutions. Municipalities can accelerate their digital transformation journey and reap the associated benefits by optimizing the interplay between bureaucratic quality, financial resources, and human capital. Based on these assertations, we present the hypothesis:

H_4. Municipalities with higher bureaucratic quality demonstrate greater levels of digital transformation.

2.5 Mayors' profiles and digital transformation

There is a consensus that older individuals are less likely to engage with digital technologies, exhibit lower trust in e-government services than younger generations, and, consequently, are less inclined to adopt e-government practices (Faber et al., 2020; Ruano De La Fuente, 2014). In this sense, it is possible to assume that younger mayors are more digitally savvy and open to innovation, making them more likely to embrace technology-driven solutions. Additionally, their higher education levels equip them with the knowledge and skills necessary to understand and navigate the complexities of digital governance (B. Fan & Pan, 2023).

Also, younger mayors are more likely to cater to the working population's needs, who often prefer digital interactions for convenience and efficiency (Budding et al., 2018). By prioritizing e-government initiatives, these mayors can enhance citizen engagement, streamline services, and improve overall governance. It is also worth noting that the influence of top-down pressures from higher levels of government can incentivize local leaders to prioritize digital transformation (Z. Fan et al., 2020; Yun & Opheim, 2010). By controlling factors such as the mayor's age, tenure, and previous experience, it is possible to isolate better the impact of youth and education on digital transformation efforts (Zhu & Zhang, 2019). In this scenario, we present the last hypothesis:

H_5. Municipalities led by younger mayors with higher levels of education exhibit greater levels of digital transformation.

3. Methods

3.1 Data Selection

The Regional Center for Studies on the Development of the Information Society (Cetic.br) is a department of the Brazilian Internet Information and Coordination Center (NIC.br), created in 2003 and linked to the Brazilian Internet Steering Committee (CGI.br) (CGI.BR, 2023). For decades, the organization, in partnership with the Brazilian Institute of Geography and Statistics, has developed research and produced data and analyses that support public policies and strategies for creating the information society, ICT use, digital transformation and internet accessibility in the country.

Since 2017, CETIC has consistently engaged all subnational governments in Brazil to generate data on technology adoption and digital transformation processes in municipal administrations. We utilized the Cetic.br database containing data from Brazilian municipalities collected in the 2023 survey. Although Brazil comprises 5,570 municipalities, the survey received responses from only 4,265 of them, constituting our sample.

The dependent variable in this study is Digital Transformation, constructed based on indicators encompassing the dimensions of Technological Infrastructure and Digital Service Provision in local governments (APPENDIX A), with data extracted from the CGI.BR – Comitê Gestor da Internet no Brasil (2023). As independent variables, we utilized indicators that measure economic and technical-administrative dimensions, as presented in Table 1. In this research, variables associated with information technology governance in city halls were measured, such as the presence of specific IT sectors, the development of strategic planning, the adoption of information security measures, the application of data protection policies and the training of civil servants on the General Personal Data Protection Act (LGPD). These elements form part of the dimension known as Technological Structure.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

On the other hand, in the Digital Public Services dimension, actions aimed at digital transformation in municipal administrations were considered, including the provision of digital services through applications for citizens, integration with the Gov.br single login, and the provision of digital solutions for issuing documents, invoices, slips, registrations and online appointments.

Tab. 1 – Overview of Regression Model Variables

Variable	Type	Description	Source	Dimension
Digital Transformation	Dependent	An index measuring the degree of technological infrastructure and digital service provision	CETIC	Technological and digital public services
IT Expenditures	Independent	Measures of how much the municipality spends on IT	Brazilian Government Accounting and Fiscal Information System (Siconf)	Economic
Intergovernmental Transfers	Independent	Measures of how dependent or autonomous the municipality is on revenues from the Union and State	System of Information on Public Budgets in Health (SIOPS)	
Municipal Revenues	Independent	Measures of how much financial resources come from own revenues	System of Information on Public Budgets in Health (SIOPS)	
Bureaucratic Qualification	Independent	Measures the percentage of the municipal bureaucracy with higher education	Gov. Munic – Laboratory of Applied Research	Technical-Administrative
Local Management	Independent	Measures the local management of the municipality	Superior Electoral Court (TSE)	

Source: From the authors.

In the economic domain, we considered Information Technology (IT) expenditures, which reflect municipal spending in this area, using data from the Brazilian Government Accounting and Fiscal Information System (Siconf), which compiles financial information from all areas of municipal public administration. We also included intergovernmental transfers, which measure the proportion of resources received by municipalities from state and federal governments and municipal revenues, with data collected from the Health Public Budgets Information System (SIOPS).

In the technical-administrative dimension, we utilized the variable of bureaucratic qualification, which measures the percentage of municipal civil servants with higher education, using information from Gov.Munic – UFRGS Applied Research Laboratory. Finally, we analyzed aspects related to the administrative management of municipal governments, including data on the gender and age of mayors collected from the Superior Electoral Court (TSE). These variables provide a comprehensive basis for understanding the factors influencing Digital Transformation in municipalities.

3.2 Analysis Technique

We constructed the dependent variable (Digital Transformation) using indicators from two main dimensions: Technological Infrastructure and Digital Service Provision in local governments. The data was extracted from the CGI.BR (2023), conducted by Cetic.br. For its construction, we employed binary factor analysis due to the binary nature of the analyzed indicators.

After correlation analysis, the selected indicators were grouped into three factors per dimension to estimate the specific weights for each variable (Medeiros et al., 2023). The process of constructing the Digital Transformation variable followed the steps: analysis of the correlation matrix; selection of the factorial method; extraction and determination of the number of factors; factor rotation; interpretation of factors; and computation of factor scores (Siqueira et al., 2015).

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Binary factor analysis was chosen based on *a priori* criterion, which predefines the number of factors retained. For factor rotation, we decided on the VARIMAX method due to its ability to maximize the variance of factor loadings, making it suitable for interpreting the underlying structure of the variables. After extracting the factor loadings, we applied the obtained weights to the data of the 4,265 municipalities, assigning a score to each observation. This score resulted in a scale from 0 to 11, where lower values indicate lower Digital Transformation and higher values indicate higher Digital Transformation at the local level.

Based on the Digital Transformation variable, we used multiple linear regression to test our hypotheses. In Equation 1, $DigTransf_i$ is the index that reflects the degree of adoption of technologies and digital services in subnational governments based on Technological Infrastructure and Digital Service Provision indicators. Then, we use the determinants that drive the digital transformation process in Brazil.

Equation 1: Digital transformation index

$$DigTransf_i = \alpha + \beta\, TI_Exp_i + \gamma\, Inter_Transf_i + \delta\, Mun_Rev_i + \eta\, BurQuali_i + \theta\, Gender_i + \lambda\, Age_i + \mu\, Education_i + Region * Pop_Size$$

Our study proposes the following independent variables: TI_Exp_i, $Inter_Transf_i$, Mun_Rev_i, $BurQuali_i$, $Gender_i$, Age_i, $Education_i$, and the interaction between Region and Population size as control variables. The first three variables correspond to the economic dimension. TI_Exp_i measures the municipalities' capacity to invest in technological infrastructure. High expenditures indicate a higher priority, and resources allocated to technological modernization may be directly related to the level of Digital Transformation. The variable $Inter_Transf_i$ analyzes the proportion of resources originating from state and federal transfers, measuring the municipality's dependence on other levels of government. Finally, the variable Mun_Rev_i measures the local tax collection capacity, a crucial indicator of financial autonomy.

Regarding the technical-administrative dimension, $BurQuali_i$ measures the percentage of municipal civil servants with higher education and indicates the quality of human capital available in public administration. A more qualified bureaucracy tends to adopt and implement technologies more efficiently, favoring Digital Transformation. Finally, the variables $Gender_i$, Age_i and $Education_i$ measure the profile of the mayors and offer insights into political leadership and its openness to innovation.

To better isolate the relationship between the independent variable of interest and the dependent variable and get a more accurate and precise understanding of the proper relationship between them, we added two variables to the model to control the characteristics of the municipalities: the region in which the city/town is located (North, Northeast, Midwest, South and Southeast) and population size, the number of inhabitants in the city/town.

4. Findings and Discussion

When analyzing the level of Digital Transformation in 4,265 Brazilian municipalities in 2023, we observed that the economic dimension became a driver for the innovation process in public administration (Table 2). Alternatively, the three selected variables were statistically significant, with one exhibiting an inverse relationship and two displaying direct relationships.

There is a negative relationship between intergovernmental transfers and digital transformation; for every unit increase in intergovernmental transfers, the digital transformation (dependent variable) decreases by 0.012334 units. That is, as government transfers rise, digital transformation tends to decline, which confirms the H1, higher levels of intergovernmental transfers are associated with lower levels of digital transformation among municipalities.

We identified a positive relationship between municipal revenue generation and digital transformation; for every unit increase in municipal revenue, the digital transformation increases by 0.030738 units. Based on this, we accept H2, which states that municipalities with higher revenue generation tend to invest more in digital transformation. In other words, financial resources are essential to enable investments in technologies and digital infrastructure.

This relationship is directly associated with the level of IT expenditure at the municipality level. Also, a positive relationship was found between IT expenditures and digital transformation; for every unit increase in municipal IT expenditures, the digital transformation increases by 1.318e-08 units. In this regard, we accept H3, affirming that municipalities that allocate a portion of their expenditure to IT have a more advanced digital transformation process locally.

When considering all variables in a full model while accounting for municipal characteristics, we observed a loss of statistical significance for all the economic variables (intergovernmental transfers, municipal revenue generation and IT

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

spending). However, a positive relationship was found between region and population size; municipalities located in the Midwest region, with a population between 50,000 and 100,000 inhabitants, are positively associated with digital transformation. Similar results were found for Northeast, Southeast, and South Brazilian municipalities.

Tab. 2 – Economic dimension (descriptive statistics)

		Economic Dimension				
		Estimate	**Std. Error**	**t value**	**Pr(>|t|)**	**Full Model** (Pr(>|t|)

Source: From the authors.

Our analysis indicated a significant relationship between the economic variables when assessed individually. However, in the full model, this relationship loses statistical significance, suggesting a weak relationship between variables such as investment in ICT, municipal revenue collection capacity, and capacity to generate revenue (which can be understood as less financial dependence on other subnational entities). The weakening in the full model's statistical significance may be attributed to the shared variance among the predictors and the broader scope of the dependent variable, encompassing both ICT infrastructure and the provision of digital services. In this sense, although parsimoniously, we can argue that in Brazil, similarly to China, fiscal capacities are essential for the digital transformation in local governments (Z. Fan et al., 2020, 2023). However, our results do not allow for strong corroboration of the hypotheses put forward in this study.

Brazil's municipalities have undergone countless transformations over the last thirty years since the 1988 Federal Constitution gave them more significant responsibilities and administrative, political and financial autonomy. Municipalities have become the central federal unit to which the implementation and provision of public policies, especially social welfare policies, is directed. The new attributions increased both the demands for professionalization of municipal management and the need to establish democratic or popular control of public action (Segatto et al., 2022).

Nevertheless, the level of financial autonomy of Brazilian local governments is highly varied. Some municipalities, generally those with larger populations, have a greater capacity to collect taxes and make investments, while others are almost exclusively dependent on constitutional transfers from the state and federal governments (Marenco & Cate, 2021). In this sense, we identified that the Brazilian federation's inequality also affects municipalities' ability to carry out digital transformation.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

The research by Przeybilovicz et al. (2018) showed that 10 years ago, ICT use and digital transformation in Brazil were very precarious. Despite South and Southeast regions presenting more ICT adoption and digital transformation initiatives due to their economic development processes, Brazilian states exhibited a high level of homogeneity, demonstrating that besides existent inequalities, there has been a growing increase in the use of technology by local governments and a greater supply of services via the platform. Therefore, the federal government's recent push, implemented by the National Digital Transformation Strategy, published in 2024, towards digital transformation is expected to stimulate increased adoption of these tools by Brazilian municipalities, ultimately narrowing regional gaps.

The state and regional inequalities demonstrated the result of a policy that, until this year, had not been coordinated nationally by the federal government. Thus, the different degrees of technological development and technology incorporation depend on each municipality's financial and technical capacities, which vary significantly among the more than 5,000 existing municipalities in Brazil. Only in 2024, with the National Digital Government Strategy, did the Brazilian Federal Government propose efforts to induce digital transformation in municipalities (Brazil, 2024), with the potential to reduce existing regional inequalities.

Focusing on the technical-administrative dimension (Table 3), only two variables regarding education (i.e., bureaucracy and mayors' qualifications) were statistically significant. This indicates that the qualifications of civil servants and mayors are positively correlated with digital transformation. Specifically, a higher proportion of civil servants with higher education levels is statistically associated with more advanced digital transformation processes; for every unit increase in education level, the dependent variable increases by 0.3548 units. In this regard, we accept H_4, which states that higher education levels are directly associated with digital transformation.

Also, municipalities led by mayors with completed university degrees tend to exhibit a significantly higher level of digital transformation than those led by mayors with only a completed elementary education. In other words, for every unit increase in education level, the dependent variable increases by 0.22957 units. However, the age and gender of the mayor are not associated with the digital transformation process. According to the findings, H_5 is partially accepted.

Tab. 3 – Technical-administrative dimension (descriptive statistics)

		Technical-administrative Dimension				
		Estimate	**Std. Error**	**t value**	**Pr(>|t|)**	**Full Model (Pr(>|t|)**
BurQuali[1]		0.3548	0.1415	2.507	0.0122 *	0.184316
GenderMale[2]		-0.01314	0.07553	-0.174	0.862	0.759449

Source: From the authors.

When controlling municipal-level characteristics, we observed a negative association between the digital transformation process and cities in the Midwest region, with populations ranging from 20,000 to 50,000. More specifically, these municipalities demonstrate a decline of -0.6832 units in the digital transformation index. Furthermore, the reduction in the digital transformation index is more substantial for municipalities located in the Northeast region, amounting to -1.195137 units.

Our analysis indicated a significant relationship (even if faintly) between the bureaucracy quality and the mayor's university degree in digital transformation when assessed individually. However, the mayor's age, gender and age group did not show statistical significance. Yet, in the full model, this relationship loses statistical significance, suggesting that

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

there is a relationship — albeit weak — between variables. As pointed out, this weakening in the full model can also be attributed to the shared variance between the predictors and the broader scope of the dependent variable, encompassing both ICT infrastructure and the provision of digital services.

Investigations conducted in other countries have shown that age and gender can significantly influence technology adoption. For instance, studies in Korea found that younger policymakers are more likely to be active innovators (Hong et al., 2022). Similarly, research in Australia revealed that the manager's gender plays a crucial role in technology adoption (Alam et al., 2022). Alam et al. (2022) identified that female managers are more likely to leverage social networking platforms than their male counterparts. Furthermore, Onozaka and Nemoto (2023) highlighted that countries with higher female representation in the middle to senior management positions exhibit greater integration of digital technologies and more sophisticated ICT tasks performed by women.

However, our findings in Brazil did not reveal a significant impact of the mayor's age and gender on the adoption of technologies by local governments to offer platform services. This suggests that while these factors may be crucial in other contexts, their influence may vary significantly across different cultural, social, and political environments. These data reinforce the idea that in Brazil, factors associated with the bureaucracy and the mayor's formal education are more relevant to adopting digital technologies, and sociodemographic characteristics matter less – although the strength of this correlation is lost in the full model. The fact that the model adopted showed no statistical difference between men and women may be because most mayors in Brazil are men, reinforcing gender inequality in access to local political careers.

5. Conclusions and Recommendations

This study contributes to academic literature and public managers by identifying the drivers of digital transformation in local governments in Brazil. The research results converged with part of the scholarly literature, mainly on cultural aspects of digital transformation (Mergel et al., 2019). We also found that economic dimensions such as tax revenue capacity, investment in ICT, and less dependence on central and state government funding are important factors in leveraging digital transformation in the Brazilian local contexts, such as the bureaucracy and mayors' education levels. Nonetheless, the statistical significance became weakened in the full model (adopting the control variables).

There has been a change of focus in public administration theories in the last decade, where the focus has moved away from the idea of the internal efficiency of public administration and endogenous discussions in organizations to a primary focus on offering services and creating value for citizens (Osborne et al., 2013; Panagiotopoulos et al., 2019). The creation of public value through the provision of services has become one of the main mantras of digital transformation. However, we must still understand how digital transformation creates public value (Mergel et al., 2019). Our research highlighted significant advancements in many Brazilian local governments while exposing persistent inequalities. Disparities in ICT investment capacity, tax collection, and bureaucratic quality directly impact the provision of digital services. These factors, in turn, influence public value creation through service delivery. For digital transformation policy to develop effectively, policymakers need to pay attention to the characteristics of local governments.

The digital transformation in Brazil has been a dynamic and challenging process, driven by the growing need to adapt to new technologies and the pursuit of greater efficiency and competitiveness. In this context, the Brazilian regulatory framework has evolved to accompany this transformation, creating various laws to foster innovation, protect personal data, and ensure cybersecurity (Filgueiras et al., 2019). The Brazilian federal government recently redesigned its general data use and protection law, instituting new guidelines for all Brazilian public administration agencies, including local governments. Alongside this, Brazil's central government is also driving digital transformation by gradually creating and coordinating efforts so local governments, based on federal incentives, can develop strategies to offer services via platforms (Brazil, 2024).

Finally, the study's relevance relies on its being the first to analyze local governments and examine the determinants of digital innovation in the public sector in Brazil. This research significantly contributes to the existing literature by providing valuable insights into the Brazilian context (Filgueiras et al., 2019). By investigating the factors that influence the adoption of digital technologies in Brazilian municipalities, this study helps to understand the unique challenges and opportunities local governments face to modernize public services and improve service delivery to citizens. The results of this research can inform policy decisions, guide the development of targeted interventions, and contribute to the broader discourse on digital governance and public sector innovation in Brazil. Furthermore, analyzing the context of a country in the Global South adds knowledge to the international scientific community, joining forces with other researchers.

One of the main research limitations is secondary data. Despite CETIC, which is responsible for collecting data on the use of ICT and digital transformation in Brazilian municipalities, there is always a percentage of non-response to the survey. Moreover, the research yielded varying responses for each variable, as anticipated, given the use of multiple

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

databases. Secondly, we employed a quantitative approach, relying heavily on numerical data and statistical analysis and risking overemphasizing measurable variables while neglecting crucial aspects such as subjective experiences, emotions, citizen-state relationships, and cultural contexts. Consequently, this research could not qualitatively capture the primary drivers of ICT adoption and online service provision in Brazilian municipalities. Our findings indicated that economic (fiscal autonomy, tax revenue collection, ICT investments) and technical-administrative dimensions (bureaucracy and mayor's education) influenced digital transformation in Brazilian municipalities. However, further research is warranted to investigate the motivations and perceptions of local managers.

Appendix A

Tab. 3 – Description of the indicators that constitute the Digital Transformation variable

Indicator	Description	Dimension
C1	Does this municipality have a dedicated IT department or division?	Technological
C1G_A	Has this municipality formally adopted an IT master plan or strategy?	
C1G_B	Does this city hall have a formally established information security plan?	
F5A	Is there a designated individual or team responsible for data privacy and compliance with the General Data Protection Law (LGPD) within this municipality?	
F5C	Have any of the employees in the city hall's IT department or area received any training, course, or workshop offered by the city hall regarding the General Data Protection Law (LGPD)?	
I1B_1_C	Has this city government made any mobile applications developed in-house for citizen use available within the past 12 months?	
D10	Does the city government offer any online services that citizens can access using the federal government's single sign-on system, Gov.br?	
H1P_A	Does the city government's website offer a service that allows users to generate tax bills or other payment slips?	Digital Public Services
H1P_C	Does the city government's website offer a service that allows users to issue electronic invoices?	
H1P_F	Does the city government's website offer a service that allows users to issue documents such as licenses, certificates, permits, and others?	
H1P_G	Does the city government's website offer a service allowing users to register or enroll for contests, courses, and schools?	
H1P_H	Does the city government's website offer a service that allows users to schedule appointments for consultations, services, and other matters?

Abstract. Digital transformation (DT) is a critical challenge for public administration, requiring municipalities to modernize services while overcoming bureaucratic inertia and workforce resistance. Hence, many German states have recently invested in municipal digital change agent (MDCA) initiatives (kommunale Digitallotseninitiativen) to facilitate and accelerate the DT process within municipalities. However, the effectiveness of such initiatives remains underexplored, as public sector constraints differ from those in private organizations, and due to their novelty. This study adopts a case study design using interviews and document analyses to examine the effectiveness and potential of MDCA initiatives. The findings indicate that the success of digital change agents is contingent on clearly defined roles, effective communication strategies, and adequate resource support. The findings highlight key drivers of success, including digital capabilities, appointing dedicated digitalization staff, fostering proactive employee initiatives, participatory leadership, proactive communication, (re)building trust, and personal benefits. However, several challenges impede MDCA's effectiveness, such as unclear role definitions, insufficient training, lack of assigned responsibilities and communication, resource scarcity, and inadequate leadership support. Structural obstacles, such as low prioritization of digitalization, absence of incentives, and resistance from tenured employees, further restrict progress. The study derives four propositions regarding the effectiveness of MDCA initiatives and DT enhancement in public administration: Clearly defining the MDCA role and responsibilities, assigning DT responsibilities to managers, increasing visibility and prioritization of DT, and introducing incentive mechanisms to foster engagement. These insights contribute to the literature on DT and change management in public administration, highlighting the need for structured frameworks and accountability measures. While MDCAs can act as catalysts for digital change, their effectiveness depends on strategic alignment, leadership commitment, and adequate resource allocation.

Keywords. Digital Transformation, Internal Change Agents, Public Administration, Municipalities, E-government

1. Introduction

Governments worldwide are changing in the light of DT, aiming to enhance process efficiency and improve public service delivery (Twizeyimana & Andersson, 2019). Municipalities play a particularly critical role in this process, as they are the first point of contact for many citizens, providing the majority of the national, state, and municipal public services. Effective digitalization can help enhance service delivery and accessibility, optimize resource allocation, and mitigate workforce shortages. Furthermore, governments face growing pressure to digitize services, increase transparency, and foster citizen engagement in response to evolving societal and technological demands (Jahn et al., 2024).

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

However, public sector organizations in Germany encounter unique challenges in adopting DT (Ritchie, 2014). Legal constraints, bureaucratic inertia, and risk aversion slow progress, as a workforce accustomed to traditional processes often resist new technologies (Kussel et al., 2024; H. Markus & Meuche, 2022). Public authorities operate strictly within the boundaries of legal provisions, meaning that any change to processes has emerged from the law. If regulations do not explicitly require digital workflows, there is little motivation or incentive to implement them, as they lack the legal basis to justify financial resources from tax funds (Ritchie, 2014). Beyond legal constraints, institutional inertia and resistance to change present additional challenges. Employees accustomed to well-established administrative procedures for decades may view digitalization as a disruption rather than an improvement. Unlike private-sector organizations, where competition and efficiency pressures drive innovation, public administration operates under long-term stability principles, making change slow and complex. In addition, DT extends beyond mere technology adoption; it requires a fundamental cultural shift, which is often underestimated (Bannister & Connolly, 2014; Kuhlmann & Heuberger, 2023). Thus, implementation requires people familiar with the process to make the necessary local adjustments. To address these challenges, several German states have introduced MDCA initiatives (Kommunale Digitallotseninitiativen) to support and accelerate DT in municipalities (Fischer & Breaugh, 2024). MDCAs are internal employees who receive external training to assist their colleagues and facilitate DT (Fischer & Breaugh, 2024). However, the municipalities struggle to measure the effectiveness of such initiatives because private sector change management metrics are not easily transferable due to differing objectives (shareholder value vs. public value (Moore, 1995; Segura-Tinoco et al., 2020)) and workforce demographics and culture. For instance, in German public administration, 26% of employees and 31% of political leaders are over 55, often lacking digital education (H. Markus & Meuche, 2022).

The existing literature on DT in public administration covers various aspects of change management, strategy, and transformation progress (Kuipers et al., 2014; Tangi et al., 2021; van de Voet, 2014). However, much of this research focuses on high-level strategies and transformation outcomes (e.g., Gong et al., 2020), while the evaluation of specific measures and influencing factors remains underexplored (Buick et al., 2018; Heuberger, 2020; Kuipers et al., 2014). In contrast, change agents literature in the private sector is more developed, with numerous studies identifying success factors, impact areas, and facilitation methods (Bünnagel, 2021; Parry et al., 2014).

However, there is limited research on internal change agents in public administration, with existing studies primarily focusing on the role of managers and their influence on organizational change (Pittaway & Montazemi, 2020; Tangi et al., 2021; van de Voet, 2014). As a result, lower-hierarchy change agents, such as regular MDCAs, remain understudied despite their potential impact on DT. Kuipers et al. (2014) highlight that research often lacks detailed analyses of change processes and their outcomes in public organizations, leaving a gap in understanding how change unfolds and is sustained in governmental settings. This gap underscores the need for further empirical research into the role, effectiveness, and evaluation of internal change agents in public administration. Additionally, most public sector studies prioritize the content and context of change over the actual transformation process and its outcomes (Kuipers et al., 2014). While public sector DT is often technology-driven, cultural and social aspects – such as leadership, regulations, and workforce adaptation – are equally important but frequently overlooked (Kuhlmann & Heuberger, 2023; Mergel et al., 2019; Tangi et al., 2021). Successful DT requires organizational readiness and leadership-driven change, not just technical system upgrades. Moreover, the role of MDCAs is a relatively new and underexplored phenomenon. Most research on change agents focuses on private-sector contexts, leaving limited empirical work on their role and effectiveness in public administration, particularly in facilitating cultural and technological change (Fischer & Breaugh, 2024; Kuhlmann & Heuberger, 2023). Without such evaluations, whether these programs are effective and should be scaled further remains unclear. This gap leads to the following research question: *What factors influence the effectiveness of the municipal digital change agent initiative?*

To address the question, we conducted an exploratory case study (Yin, 2014) to investigate the effectiveness of an MDCA initiative in southern Germany. Our data collection includes 34 semi-structured interviews, analyzed through an abductive coding approach comparing success factors from the literature to the case. Additionally, we incorporated document analysis, informal discussions with the project team, and participation in initiative events for triangulation. To assess the impact of MDCAs, we compared practices and digitalization levels between departments with and without MDCAs. Furthermore, a case comparison with another municipality in southern Germany supports the robustness of the findings.

The study identified key drivers and challenges of MDCA initiatives in public administration. Effective MDCA initiatives and DT are driven by building digital capabilities, appointing dedicated digitalization staff, fostering proactive employee initiatives, encouraging participatory leadership, promoting proactive communication, building trust, and offering personal benefits. However, challenges such as unclear MDCA role definitions, unassigned responsibilities, lack of communication, resource scarcity, limited training, and insufficient leadership support hinder MDCA's effectiveness. Additionally, structural barriers like weak change incentives and low prioritization of digitalization efforts further impede progress. The study concludes with propositions and recommendations for effective MDCA initiatives.

Our study contributes to DT and change agents literature in public administration by examining the effectiveness of MDCA initiatives in a quasi-voluntary setup (Fischer & Breaugh, 2024). By identifying key drivers and challenges, we offer empirical insights into MDCA initiatives and the role of non-management level MDCAs in accelerating DT. Additionally, our findings broaden the discourse on change agents by shifting the focus from leadership roles to regular employees (Pittaway & Montazemi, 2020). The derived propositions serve as a foundation for future research to empirically validate, and the proposed recommendations can be used to set up more effective MDCA initiatives.

2. Theoretical Background

2.1 Change and Digital Transformation in Public Administration

The concept of change and change management encompasses numerous definitions, with "organizational change" being the most commonly used term. van de Ven and Poole (2014) define change in an organizational context as a transformation in form, quality, or condition that can be empirically observed over time. Organizational change involves not only adjustments to structures, systems, and processes but also psychological effects on employees (Choi, 2011). At the same time, employees can significantly influence the change process (Choi, 2011).

DT describes changes in core practices, competencies, processes, as well as (organizational) culture and mindset (Gong et al., 2020). The literature increasingly refers to a continuous change driven by digital technologies, aiming to improve or transform processes through information, computing, communication, and netwosrking technologies (Haug et al., 2024; Vial, 2019). Although governments, states, and municipalities conduct a variety of planned change initiatives, many scholars describe DT in public administration primarily as an emergent process, where incremental changes accumulate into a broader transformation (Kickert, 2010; Mergel et al., 2019). This is because DT is often viewed as a continuous process, in contrast to earlier e-government initiatives, which were characterized by a defined start and end date, a measurable outcome, and a fixed budget (Kickert, 2010; Mergel et al., 2019).

Research also associates DT in public administration with more efficient internal processes, expanded information provision, and a transformed relationship with citizens and businesses (Ndou, 2004). Additionally, bureaucratic structures pose a challenge as they can hinder the adoption of new technological innovations (Lekkas & Souitaris, 2023). Furthermore, the shortage of IT professionals and difficulties in recruiting qualified personnel complicate the implementation of such initiatives (Czernich et al., 2021). Research and practice have shown that successful DT relies on individuals familiar with the processes to implement local adjustments. At the same time, a fundamental cultural shift is necessary to better integrate digital elements into workflows and enable sustainable change (Heuberger, 2020). However, the subsequent organizational culture transformation is often overlooked in the context of DT in public administration and usually follows the technical digitization process (Tangi et al., 2021). In addition to technological aspects, social factors play a crucial role but are frequently underestimated (Bannister & Connolly, 2014; Kuhlmann & Heuberger, 2023). Thus, an increasing number of public administrations use the concept of internal change agents.

2.2 Internal Digital Change Agents

In the context of change initiatives, individuals or teams, known as change agents, can take on the initiation, promotion, or implementation of change initiatives (Caldwell, 2003). A distinction can be made between internal (employed staff) and external (external staff, e.g., consultants) change agents (Caldwell, 2003). Internal change agents address individual reactions to change (Wylie & Sturdy, 2018) or promote change (M. L. Markus & Benjamin, 1996). Studies have examined a variety of aspects of this concept, such as the influence on resistance (Battilana & Casciaro, 2013; Ford, Jeffrey D., Ford, Laurie W. & d'Amelio, 2008), acceptance and readiness benefits (Armenakis et al., 1993; Hemme et al., 2018), as well as individual workplace behavior (Parke et al., 2021). For instance, in Lewin's 3-phase model, change agents support readiness in the first phase, promote acceptance and exploration of the change in the second phase, and consolidate the progress made in the third phase (Armenakis & Bedeian, 1999; Burnes, 2004; Wylie & Sturdy, 2018). In this study, we focus on internal change agents based on Wylie and Sturdy (2018). The authors define them as individuals in permanent employment who dedicate part of their role to managing change, actively contributing to defined change projects or programs, and being part of a team or unit with a clearly assigned responsibility for implementing change. Thus, we define MDCA as trained internal employees facilitating DT within a municipal organization like a city administration. Another dimension for change agents is their role within the organization, whether in a leadership position or as regular employees (Parke et al., 2021; Specht et al., 2018). Regardless of their role, a strong network within the organization and effective change communication are key success factors (Battilana & Casciaro, 2013).

For a successful DT, processes, regulations, employees, and especially leadership must be adapted (Mergel et al., 2019). The literature emphasizes the crucial role of managers, as they exert the most significant influence within hierarchical structures (Kuipers et al., 2014; Pittaway & Montazemi, 2020). DT significantly impacts the

relationship between public managers and employees, requiring managers to emphasize relationship management, participatory leadership, and clear frameworks to effectively engage their employees (Gilli et al., 2024). Research focuses on the role and influence of leadership, identifying managerial support as a critical factor (Kuipers et al., 2014; Pittaway & Montazemi, 2020). Studies address topics such as the perception of DT (Mergel et al., 2019), challenges (Moser-Plautz, 2024), the impact of communication on employee readiness (Hameed et al., 2019), DT expertise of leaders (Pittaway & Montazemi, 2020), and the role of middle management as change agents in managing resistance (Buick et al., 2018). Buick et al. (2018) found that middle management change agents can effectively facilitate transformation and reduce resistance if adequately supported. However, the role and effectiveness of MDCAs, who are not exclusively in management positions, have been neglected in existing research.

MDCA initiatives aim to accelerate DT in cities, municipalities, and districts. They act as an interface between administration, citizens, and businesses to efficiently facilitate the DT in public administration (Fischer & Breaugh, 2024). The first approaches to such programs emerged in Germany in 2018 when the first federal states in southern Germany began deploying administrative staff as MDCAs following specialized training to support administrations in digitalizing processes and services. These programs were further developed in subsequent years and adopted by other federal states. During the COVID-19 pandemic (2020–2021), digitalization gained significant traction, further increasing the relevance of MDCAs. Many German cities implemented such programs to systematically address the challenges of DT.

2.3 Impact Areas of Internal Change Agents

The effectiveness of internal change agents in enhancing DT depends on their skills and the organizational areas they can impact. This chapter summarizes three core impact areas: employee support, resistance management and acceptance, and networking. All impact areas contribute to the workforce's acceptance of and willingness to change and are thus relevant for internal change agents such as MDCAs. While internal change agents can facilitate communication, foster readiness for change, and mitigate resistance (Buick et al., 2018), their effectiveness depends on leadership backing and sufficient resources (Fischer & Breaugh, 2024).

Impact areas are the key domains where change agents influence organizational transformation, defining where and how their actions drive change. Employee support comprises two key areas: social support and the promotion of self-efficacy. *Social support*, a central focus of change agents, includes emotional, instrumental, informational, and appreciative support (Bünnagel, 2021; Fischer & Breaugh, 2024). *Emotional support* aims to reduce fears and foster readiness for change through empathy, trust, and active listening (Endrejat et al., 2021). *Instrumental support* provides practical help, such as assistance with information systems, while *informational* support focuses on the structured sharing of explicit and tacit knowledge (Bünnagel, 2021; Fischer & Breaugh, 2024). *Appreciative support* enhances self-efficacy through constructive feedback and the recognition of achievements (Bünnagel, 2021). Promoting *self-efficacy* focuses on strengthening employees' personal traits that enhance openness to change. Self-efficacy is a key factor in successfully navigating change processes (Armenakis et al., 1993; Kuntz & Gomes, 2012). Overall, support from change agents contributes to fostering readiness for change and overcoming challenges in the transformation process.

Managing resistance is one of the core responsibilities of change agents (Angehrn & Atherton, 1999; Endrejat et al., 2021). They can create an understanding of change by highlighting its necessity and urgency (Armenakis & Fredenberger, 1997). In addition, change agents are expected to convince employees of the change and increase their willingness to embrace it by demonstrating organizational and personal benefits (Armenakis et al., 1993; Hemme et al., 2018). It is crucial for employees to recognize that the change is achievable and that they possess the skills required to implement it successfully, also known as resilience (Armenakis & Fredenberger, 1997). Clearly defined and achievable goals can further build trust in the change process (Kuntz & Gomes, 2012). Another goal of change agents is to foster a sense of accountability for the change among employees (Angehrn & Atherton, 1999). They should also confidently handle critical reactions and effectively manage conflicts (Pádár et al., 2017). Furthermore, they should address problems directly and confront underperforming employees or leaders when necessary (Furnham, 2002).

Managers play a unique role in change processes as they can impact areas beyond the influence of regular change agents, increasing the impact. Managers can influence DT at various hierarchical levels and in different ways. Lekkas and Souitaris (2023) distinguish between higher-level and lower-level managers: while senior managers initiate or approve changes, their lower-ranking counterparts are primarily responsible for operational implementation. Higher-level managers are tasked with developing visions and strategies for transformation (Fernandez & Rainey, 2006). This includes formulating a clear vision, defining goals, outlining expected outcomes, and assessing their impact on respective departments (Caldwell, 2003; Westover, 2010). Additionally, they are responsible for initiating the change process (Caldwell, 2003), ensuring the provision of adequate resources (Caldwell, 2003; Fernandez & Rainey, 2006), and overseeing progress to evaluate the success of the transformation (Angehrn & Atherton, 1999; Bünnagel, 2021). Lower-level managers play a crucial role in engaging employees at

the operational level. In addition to managing resistance (Westover, 2010), they can encourage employees to adopt new technologies (Caldwell, 2003). Gathering feedback, such as on new software, and organizing training programs are also central responsibilities (Fernandez & Rainey, 2006; Westover, 2010).

To enhance employee involvement, bottom-up initiatives are often promoted (Hansen & Nørup, 2017), and employees are integrated into decision-making processes (Angehrn & Atherton, 1999; Hansen & Nørup, 2017; Westover, 2010). Participation in implementation can further increase employees' acceptance of change initiatives (Fernandez & Rainey, 2006). While a participative leadership style improves change acceptance, a more directive leadership approach is recommended for performance-oriented implementation (Hansen & Nørup, 2017; Westover, 2010). Managers can also employ various motivational strategies. Besides traditional incentives, persuasion, rewards, and guarantees against potential disadvantages, they may also use critical feedback, pressure, or coercion (Fernandez & Rainey, 2006). Supportive measures such as psychological assistance or symbolic ceremonies can also facilitate transformation processes (Fernandez & Rainey, 2006). Managers at all levels can also influence change passively by demonstrating acceptance and commitment to transformation through their own attitudes and behaviors, thereby signaling their support for the process (Armenakis et al., 1993).

3. Method

MDCA initiatives are still a quite new approach that an increasing number of cities implement to accelerate their stagnating DT activities. The review of the literature revealed a lack of empirical evidence on the effectiveness and success of such initiatives (Kuhlmann & Heuberger, 2023; Tangi et al., 2021). When conducting the study, the literature provided little empirical evidence on the effectiveness and success of such initiatives. Therefore, we deem an exploratory case study approach suitable for the study (Yin, 2014).

3.1 Case City

For this study, we collaborated with a major city (with a population of at least 100,000 – in our case, less than 200,000) in southern Germany. The city implemented MDCAs in its municipal administration in 2019. According to their current concept, MDCAs serve as multiplicators for DT, aiming to reduce fears and concerns while motivating employees to actively contribute to its implementation. The MDCAs are part of their digital strategy, which targets DT across nearly all administrative areas, resulting in the deployment of MDCAs in almost all departments. The case city emphasized that every employee – regardless of the role or hierarchy level – is welcome to participate in the training and to qualify as MDCA.

The initiative is coordinated by the Department for Digitalization and IT Planning (Digitalization Department). The MDCAs are municipal employees who undergo three-day seminars to be trained as ambassadors for digitalization. During the training, they receive basic knowledge of DT and Change Management. The program aims to actively involve employees in the DT. The main tasks of MDCAs in the case city include informing colleagues about the city's digital activities, enhancing the understanding of DT, serving as advisors and supporters to mitigate concerns and fears, the proactive proposal of ideas to advance DT, driving cultural change by exemplifying a digital mindset, supporting organizational units in communicating their digital needs as well as implementing the digitalization strategy and actively shaping the DT. For these tasks, five working days per year are allocated for MDCAs. Additional initiatives can be pursued beyond regular working hours. Consequently, the role is quasi-voluntary.

3.2 Data Collection and Analysis

We used several information sources to collect data and enable data triangulation (Yin, 2014). Therefore, we conducted 34 semi-structured interviews, participated in an MDCA networking event day, protocoled the observations from the event and from informal meetings with the project leaders, and analyzed internal documents. The case city comprises 38 departments, ranging from the citizens' office to the city treasury and facility management. At the time of data collection in early 2024, 17 of these departments hosted 27 MDCAs, leaving 21 departments without an MDCA. To comprehensively analyze the effects of the MDCA initiative, we interviewed MDCAs, their managers, and employees from departments with MDCAs. In departments without MDCAs, we interviewed managers and employees to gather comparative insights. As summarized in Table 1, a total of 34 interviews were conducted – 28 in departments with MDCAs and 6 in departments without MDCAs, the latter reporting a high degree of digitalization. Specifically, in departments with MDCAs, we conducted 10 interviews with MDCAs, 8 with MDCAs in management positions, 4 with regular employees, and 6 with managers. In departments without MDCAs, interviews included three employees and three public managers across three departments. The sampling was balanced to account for the MDCAs' years of experience, as we anticipated that greater experience would correlate with higher impact (Myers & Newman, 2007). Interviews ranged from 24 to 77 minutes, averaging 43 minutes. The sampling process was influenced by employee availability, resulting in last-minute cancellations and adjustments, including the replacement of interviewees.

Tab. 1 – Interview Sampling (MDCA-M = Municipal Digital Change Agent-Manager, E = Employee, M = Manager).

Department	MDCA	MDCA-M	E	M
6 with MDCAs	10	8	4	6
4 without MDCAs	N/A	N/A	3	3

Based on the literature review, the informal discussions with project management, and the document analysis findings, an interview guide was developed to gain a deeper understanding of the experiences, perspectives, and attitudes of the MDCAs. It covers key topics such as resistance management, digital competencies, readiness and willingness to change, acceptance, change agent training, challenges and success factors, and the perception of the MDCA initiative and the MDCAs themselves. The interviews aimed to gather insights into the extent to which actual experiences and practices align with the concepts described in the literature and the goals pursued by the city. Semi-structured interviews were conducted to achieve comparable results while still capturing the diversity of MDCA mechanisms (Myers & Newman, 2007). During a full-day MDCA networking event, we talked to the MDCAs, participated in the discussion rounds, and summarized all impressions and observations in a joint protocol (Yin, 2014). The observations covered the agenda, self-perception, wishes, complaints, and tasks mentioned by the MDCAs, presented facts about the initiative in the case city and relevant quotes per topic. As for the document analysis, we included training documents, the digital strategy of the case city, their MDCA concept, annual reports, an internal MDCA toolbox, protocols of the meetings with the MDCA project leaders, and presentations (if available) from the networking events.

The data analysis followed an abductive coding approach based on concepts from the literature while drawing on grounded theory to identify emerging themes and patterns (Eisenhardt, 1989; Gioia et al., 2013). The analysis focused on identifying the drivers and challenges of the current MDCA initiative regarding DT for a comprehensive understanding of its implementation. We employed triangulation across all data sources to enhance reliability and validity (Yin, 2014). To enhance the robustness of our study, we incorporated insights gained through a public meeting from another city (>150,000 inhabitants) in southern Germany. The city (City-2) implemented the same MDCA initiative following the same state-led training initiative and conducted an internal evaluation.

4. Results

4.1 Drivers of Municipal Digital Change Agents and Digital Transformation in Public Administration

This section presents the drivers for MDCA initiatives and DT in public administration identified from the case study. Table 2 summarizes all drivers at the end of chapter 4. In the following interviewee citations are indicated according to Table 1 (e.g., M1 = Manager1).

Building digital capabilities. Departments without MDCAs but with a high degree of digitalization emphasized their ability to build and capture digital capabilities by strategically hiring tech-savvy employees. Thus, focusing on digital expertise in recruitment is a key driver for their digitalization success. While most employees acquired the necessary digital skills during their professional education, several managers reported identifying tech-savvy employees within their teams and intentionally assigning them digital tasks to leverage their expertise or point them out as digitally responsible (M2; M4; M5). In addition, employees in digitalized departments are reported to be well-trained in the respective systems.

Dedicated full-time digitalization equivalent. Each digitalized department had at least one team member responsible for digital topics. These employees were typically tech-savvy individuals with a strong curiosity and intrinsic interest in digitalization, demonstrating dedication and a fundamental understanding of the relevant processes. The need for such a role stems from the increasing complexity of digitalization efforts, making a decentralized approach less viable. As one interviewee explained, *"[Digitalization] has now reached such a scale and requires consolidated expertise that we decided to create the position of a 'digitalization specialist' position within our organization to centralize the competencies previously distributed across various individuals. (...) In my opinion, decentralization no longer works. It can only function centrally, with someone who holds all the threads while involving others (...)."* (M3) While most MDCAs themselves have limited capacity for DT topics directly, they view themselves as role models*: "I see it as my responsibility to make sure that I use the city's digital services, that people can see I use them, that I can handle them, and that I also look into what else can be digitalized that hasn't been digitalized yet."* (MDCA5) By demonstrating digital competence in practice, they aim to encourage broader acceptance and integration of digital processes across their departments. Although awareness of the MDCA initiative varies, several employees who know about it appreciate having a clear point of contact for digitalization-related concerns, recognizing the necessity of guidance and structured support. *"I do think it's good to have a point of contact to turn to. Because if everything gets digitalized and there's no one you can approach with questions, it would become a bit difficult. One person might be more technically skilled, (…) and understand things more easily, while another might not. I also have to consider the older colleagues."* (M5).

Proactive employee initiatives. While various facets of proactive initiative were observed, they originate from the same underlying reasons: a strong sense of responsibility and the belief that individual actions can lead to meaningful improvements in processes and workflows. Therefore, employees demonstrated attentiveness towards their colleagues and proactively offered help where needed: *"Afterward, I did realize that there was still a need for discussion – and that not everyone understood what was happening. I then scheduled another meeting once I noticed this to provide a more fundamental explanation."* (M1, MDCA-M1). Beyond assisting, employees take ownership of digital advancements, identifying opportunities for tool development or software improvements. When they recognize inefficiencies or discover better solutions from external sources, they take the initiative to assess potential benefits and address the topic with their manager. As one manager told us: "*Now we're switching to a new software. These are initiatives that come from employees who have learned that something like this works elsewhere with certain software. It fits better. Then you look at things and consider whether you can generate added value or simplify work processes."* (M2). This mindset reflects a new culture where employees actively shape their digital environment rather than passively adapting to imposed changes, ensuring that new technologies are integrated to enhance efficiency and usability.

Participatory leadership style. This describes managers who include their employees through active communication, feedback collection, and participation. There is a strong consensus that managers should actively support DT by involving employees and providing clear strategic direction. *"Ultimately, it all stands and falls with the managers – no question about it. They must ensure persistence, advocate effectively, and act as the driving force."* (M3). Managers from these departments stated that they regularly collect feedback from team members on tools and requirements for new software, invite them to beta tests, and talk about current updates and concerns at team meetings (M2; M4). In addition, some managers mentioned celebrating digitalization successes with their teams, reinforcing motivation and a positive attitude toward change. Training programs in these departments play a key role in preparing leaders for this approach, as managers and aspiring managers are systematically trained in change management and transformation methods as part of their career development. One MDCA-M also adopted a similar approach to encourage collaborative innovation: *"[I] actually try to involve people in a dialogue and encourage them to think for themselves about what could be done. (…) It's not about me sitting in an office and deciding how things should be done, but about sitting down together and figuring out how to approach it and what solutions we have."* (MDCA-M5). A participatory leadership style creates a more sustainable and employee-driven DT process by positioning leadership as an enabler rather than a directive force.

Active communication. Active communication is also part of the participatory leadership style and can be enacted by both managers and employees. Still, regular MDCAs can use proactive communication to spread information about DT and to give feedback to their colleagues and managers on how to enhance a digital mindset*: "Well, I spoke very openly. I often said, yes, you also have to deal with it, so, of course, it was department manager and his deputy. There's no other option, you have to deal with it."* (MDCA2) Departments with strong communication structures (M3; M1) report that employees feel well-informed about digitalization and system handling (M5; M2; E2). In addition, the Digitalization Department shares information on DT, e.g., by offering practical guidance on activities like setting up mobile devices, which employees and MDCAs who use the intranet find very valuable. Furthermore, MDCAs can serve as a direct communication link between employees and the Digitalization Department. In some cases, they helped identify needs, problems, and progress within their department.

(Re-)Building trust. MDCAs build trust by engaging with colleagues, pointing out the advantages of digitalization and small efficiency gains (e.g., using email instead of internal mail), and attempting to reduce fears by building trust. In this process, having the patience to identify the root causes of those fears helped to overcome them and ultimately generate acceptance. Those who were a bit anxious can be persuaded through training and support programs. However, individuals with deeply ingrained fears often develop them due to previous negative experiences with change initiatives. Hence, they first need time to rebuild trust, as illustrated by one MDCA: *"They are really extremely afraid, and in some cases, they're 30, 40, 50 years old, working for the city (…) they've had bad experiences, they lack trust, and that was crucial. I first had to build trust. It took about a year, but then it was really, really great because they knew they could rely on me. They simply lacked a foundation."* (MDCA7). Thus, MDCAs could effectively take on the role of a trusted intermediary, facilitating smoother transitions and greater acceptance of DT efforts (MDCA7; MDCA-M5). In addition, many MDCAs reported open, trusting relationships with colleagues (MDCA5; MDCA1).

Personal benefit. Employees seemed more likely to accept change in terms of DT or take over digital responsibilities when this change comes with other benefits for them, such as remote work. One interviewee from the municipal health department explained that the introduction of remote work significantly increased willingness to adopt digital tools during the COVID-19 pandemic*: "There was resistance from employees, yes, and skepticism, no question about it. The workforce (...) has a rather advanced age, let's put it that way, and perhaps a mindset that is somewhat inflexible. (...) Many employees have been here for decades (...), and they naturally struggled a lot with the transition. (...) Ultimately, there was a significant shift when the option of working from home was introduced. Then, employees showed more willingness to embrace something new."* (E2). In addition, offering individual benefits also lowers resistance and increases readiness for digital change. *"I resisted taking on the role*

of digitalization officer for a year. (...) then I finally agreed to do it voluntarily and got a day of home office in return. That's how they got me." (E1), explained an employee from the specialist administration for the building material rights department.

4.2 Challenges of Municipal Digital Change Agents Initiatives

This chapter describes the challenges we encountered while investigating the MDCA initiative. We clustered them into organizational, cultural, and structural challenges. Each group has a different level of access or leverage for the municipalities to implement resolutions. Table 2 summarizes all challenges at the end of chapter 4.

The organizational challenges are obstacles that lie within the organizational setup of the MDCA initiative. Hence, the city has the power to overcome the challenges of this group. While the power to change is high, this does not necessarily mean that the case city has sufficient resources to implement resolution changes.

MDCA Role Ambiguity. There is significant uncertainty among the MDCAs and employees about the change agents' specific tasks and responsibilities, which has been identified as the biggest challenge. The majority of the interviewees (employees, managers, and MDCAs) stated that they were not sure about the responsibilities or duties of an MDCA. One MDCA told us directly: *"[I] am an MDCA, but I don't really know exactly what the goal is at the end of the day. I was never really informed about what was expected. There isn't much information provided (...). I'm not really sure what rights or freedoms are granted in this role, even in day-to-day work."* (MDCA4) The majority perceive themselves as a person of contact. The MDCA concept of the case city includes the following responsibilities that MDCA should take on: active information dissemination, assessment of digital needs, acting as intermediaries between relevant stakeholders, proactively contributing suggestions on how organizational units can advance, serving as a local point of contact, reporting on DT progresses, regular participation in network meetings and knowledge exchange, and contribute to the implementation of the digital strategy by engaging in workshops, real-world labs, and projects. However, further than this level, the description is quite vague in terms of SMART goals or even monitoring mechanisms. We found that two factors contribute to this discrepancy: First, minimal offers (workshops, meetings, a standardized channel for suggestions, etc.) and no reporting claimed by the Digitalization Department (which we address later), and second, a lack of communication about the role. The latter was also documented in a Q&A session following up an early MDCA networking event. Thus, we suspect that this ambiguity harmfully affects the effectiveness of the MDCA. Consequently, the MDCA role is not the primary driver of action. One MDCA explained: *"I don't know if it's due to the role of being an MDCA or if the same result would have been achieved without it."* (MDCA5). The void created by the unclear definition of the MDCA's responsibilities is filled with other topics. For instance, some MDCAs reported during a network meeting that their managers had assigned their role to select a new administrative system, and they were pleased that this selection process allowed them to shape the decision according to their personal preferences. Others complained that their colleagues perceived them as low-level IT support (MDCA4). Similarly, city-2, after an internal evaluation of their program, faced very similar challenges to the case city. The ambiguous role description results in their colleagues' perception of low-level IT support. Furthermore, the factors of gender or years of experience had no notable impact on MDCA effectiveness, highlighting that intrinsic motivation rather than structured responsibilities drove the engagement in DT activities.

Insufficient training. This refers to a lack of practical knowledge among MDCAs, as they struggle to recall content, find it too abstract, and feel unprepared for DT challenges. Most MDCAs could not name any specific content from their basic training that they have applied in their role as an MDCA or demonstrated little recollection of the training content in general. Some MDCAs expressed a desire for more in-depth training and additional information to better address the questions and concerns of their colleagues. *"If you [a colleague] have this or that problem, we take a look at your processes and see if we can simplify something (...). And then [I get] very little understanding: Why? I don't have time for that, and so on. If I knew how to approach this (...), it would have stood out to me here in particular. I honestly don't know how to make it work.,"* explained MDCA7. The analysis of the training documents revealed that change management methods were covered in addition to project management topics. However, most MDCAs seem to have struggled to translate this theoretical knowledge into practice: *"The things we did (...) I found them kind of too abstract. They didn't really help me."* (MDCA6).

Lack of clear communication. This concerns *primarily* the communication on the digital strategy, stakeholder responsibilities, and the role of MDCAs within the city *administration*. Many employees are unaware of the initiative and its impact (E6). The lack of visibility limits engagement and prevents employees from recognizing the value and potential of the initiative. In addition, there are diverging perspectives on the obligation to seek and the obligation to provide information by the employees. Some believe that while digital resources and platforms already provide relevant details, MDCAs should be more active in consistently sharing and promoting it within their departments. Others argue that accessing information is a shared responsibility, emphasizing that employees should also take the initiative in seeking information on the internal platform and exploring available resources, such as internal media channels and newsletters provided by the city. MDCAs generally value their role as it often allows them to receive internal information from management earlier than others or get invited to meetings where

they are introduced to new technologies or beta testing. However, not all see it as their duty to process and share this information or meeting recaps with their colleagues. This is less about deliberately withholding information and more about the lack of responsibility and duties associated with the role. The investigation in City-2 highlights similar observations like the awareness, visibility, and recognition of the initiative.

Unclear responsibilities. We observed a significant conflict regarding the stakeholders' responsibilities in the DT's operationalization. While many employees and managers assume the Digitalization Department will initiate and lead digitalization efforts, the city's digital strategy places authority and accountability within individual divisions and departments. This was supposed to address concerns about top-down imposition, yet it creates ambiguity among all parties involved. Accordingly, several interviewees view stronger guidance from top management as essential to driving DT. Many managers, however, had a different perspective: *"(...) we are not the drivers of digitalization in the city. We are the users. We can provide suggestions, but we don't operationally drive it for ourselves."* (MDCA-M3) and later stated that the digitalization officer is in charge of operationalizing DT. On the other hand, the digitalization officer and the Digitalization Department see the higher-level and lower-level managers responsible for operationalizing the digital strategy. Regarding the MDCA initiative, according to managers, it is not the MDCA's responsibility to push forward digitization initiatives, as no resources for project management were allocated to the MDCA role. Although the execution of larger digitization projects falls under the purview of the digitization department and, thus, the digitalization officer, they cannot properly execute this task due to limited resources, as discussed later. The issue becomes even more severe when responsibilities for digitalization projects are passed back and forth until they ultimately reside in one department where the already fully occupied employees cannot manage them. For instance, MDCA has initiated the digitization of room booking processes. Shortly after, a new Building Management Office was established, but it did not want to take responsibility for the room booking digitalization project. As a result, the continuation of the initiative has fallen back to the digitization department, where progress is on hold due to limited resources. Several interviewees mentioned the mayor as head of the institution and even higher political forces such as national policymakers and the state as responsible because they were the ones allocating resources and prioritizing strategic topics such as DT (MDCA-M8; MDCA-M1; MDCA7; MDCA6; MDCA3). Most interviewees saw higher-level management in charge of initiating, driving, and prioritizing DT, while lower-level managers were expected to implement and operationalize DT efforts. Across managers and employees, there is a consensus that while DT responsibility covers multiple levels (political level, state level, mayor, etc.), each employee should actively contribute to DT within their means (MDCA-M8; MDCA-M5; MDCA-M3; MDCA1; MDCA2). However, some noted a lack of learning culture and proactive engagement to achieve this goal: *"There is too little learning culture (...) It's easier to say, 'Let someone else handle it.'"* (MDCA2). Although city-2 implemented the same quasi-voluntary approach of the initiative, their managers expected MDCA to take over responsibility for implementing digitalization projects and, like in the case city, did not perceive this responsibility as their own.

Resource scarcity. MDCAs, managers, and employees face limitations regarding time and workforce, including the Digitalization Department and the IT department. The time allocated for the MDCA activities is perceived as insufficient to effectively enhance digitalization. Since the MDCA role encompasses five working days per year, it is primarily voluntary. Hence, since employees are already fully occupied with their daily tasks, their MDCA activities are often deprioritized. *"I don't have the time for this [creating guidelines or reports]. For example, there was a request to create guidelines for meeting media, but I haven't had the time for that. Nor has anyone else. We have a high workload here.,"* explained MDCA5. City-2 reported similar observations: MDCAs face significant time constraints, with their responsibilities perceived as "on top," resulting in declining engagement. In such cases, networking meetings or training sessions are typically the first to be canceled. A higher time budget or the integration of MDCA activities into the job description would help the MDCAs to be more effective: *"And it would, of course, be helpful if specific time allocations were designated for this. In other words, being partially relieved from regular duties to have dedicated time to take on and actively carry out this task. That would help all of us tremendously"* (MDCA-M5). Similar capacity constraints forced the digitalization officer to scale back MDCA support, including temporarily suspending the Meet & Learn series, a virtual space for knowledge exchange (MDCA-M1). Furthermore, several interviewed MDCAs (MDCA10; MDCA3) did not possess their own device for participating in the online interview and had to use the only device with a camera in the department, which belongs to her supervisor. According to her manager, the shortage of technical resources and progress stems from the understaffing of the IT department: *"If the [IT department] is not well staffed, you just have to be glad if you can manage regular operations."* (MDCA-M6).

Missing structured framework. This refers to the absence of overarching offers for the MDCA initiative to be effective, such as regular networking and exchange meetings, training opportunities, or support. Although the MDCAs seem to be well-connected with their work colleagues and within their departments, they lack opportunities to exchange best practices and experiences with other MDCAs. The desire to learn from their counterparts and share experiences was raised multiple times: *"(...) I would have liked it to go a bit deeper, more like, how do you do it? I have these experiences, what are yours? So, being more in exchange."* (MDCA7). This issue originates from capacity constraints within the Digitalization Department, which oversees the initiative. Correspondingly, the MDCAs from city-2 miss offers for experience exchange and networking within the initiative.

Cultural challenges are obstacles that lie within the working culture and work demographics. Hence, the city has some power to overcome the challenges in this group. The process, however, takes much more time and effort, and the results only display in the long run.

Limited proactive engagement of MDCAs. This results from the ambiguous role of understanding the conflicting communication from the Digitalization Department (compared with the MDCA concept) and the limited accountability expected from MDCAs. According to the Digitalization Department, MDCAs are meant to play a somewhat educational role. They are intended to foster enthusiasm, influence organizational culture, and be knowledgeable about digital topics. However, the following or similar statements cast doubt on the initiative's effectiveness: In response to the question of what tasks the interviewees pursued as MDCA, they answered that they were available as a point of contact. When asked how often they are approached, they responded that they have not been contacted within the last year. Several MDCAs mentioned that they currently do not actively engage in their MDCA role within their departments (MDCA-M8; MDCA-M6; MDCA) – primarily due to time restrictions, the role ambiguity, limited intrinsic motivation, and the lack of accountability (E4). While MDCAs are generally perceived as keen to help and assist their colleagues with digital topics when approached, they seem discouraged about the limited openness of their colleagues to learn new things. *"To be honest, I don't even try to explain it to a colleague because it just goes in one ear and out the other; there's simply not much interest there."* (MDCA4). This behavior is predominantly reported for elderly personnel. Thus, younger employees might grasp the necessity of change in the light of DT faster, which we will discuss later (MDCA3).

Limited active leadership support. This refers to the passive managerial approach toward DT and MDCAs, characterized by tolerance rather than active facilitation, sometimes accompanied by managerial control concerns, organizational inertia, and a lack of a trusting feedback culture. Management support for MDCAs varies substantially across departments. Only a few interviewees, mostly MDCA managers, claimed that managers were actively involved in DT activities, often referring to their own engagement. For instance, one interviewee noted that their division management maintained an open attitude towards digitalization and covered training costs but did not mention any other active engagement (MDCA4). While the majority of MDCAs state that they do not receive support from their manager (MDCA3; MDCA3), others report that their activities as an MDCA are being tolerated or that their ideas are only checked for practicability and effort by their manager or that they have full leadership support (MDCA2; MDCA-M4). Two other managers expressed a certain reluctance towards DT by showing a lack of willingness to actively provide support (M4; M5). Managers' passivity and resistance have been frequently reported. One MDCA expressed frustration with a lack of initiative among management: *"(…) the problem is [my manager's] colleagues, the managers who work under him. I see them as the issue – they do not actively contribute, and they are not the ones shaping things. Instead, they expect to be presented with something ready-made, and then they can complain about it."* (MDCA6). This discrepancy in management engagement impacts the effectiveness of MDCAs. While some managers encourage participation and remove challenges, others exhibit skepticism, reluctance, or a fear of losing control. This notably slowed digitalization efforts and shifted the convincing responsibility onto employees (E2). This aligns with the insights from city-2, where MDCAs noted limited management support and unequal approaches from managers in releasing MDCAs from regular tasks to pursue MDCA activities.

Structural challenges are obstacles that lie within the particularities of the public sector, like their monopolistic position, incentive mechanisms, and tenure protection (Ritchie, 2014). Hence, the city has the power to overcome these challenges. The process, however, takes much more time and effort, and the results only display in the long run.

Lack of change and digitalization incentives. This refers to positive incentives like promotions or rewards and negative incentives like sanctions or disciplinary actions. In the city administration and the initiative's current set-up, there are no consequences for departments or employees who avoid digitalizing their work processes or blocking joined digitalization efforts with other departments. As a result, MDCAs and departments are left to handle the situation on their own if they encounter avoiders or strong resistance, as one MDCA remembers: *"[There are people] who simply don't want to. And if there isn't much pressure from the city, they don't feel obligated to do it either. Or if their manager doesn't explicitly tell them to, they just don't do it. There's really nothing you can do about it."* (MDCA7). According to several interviewees, a key challenge is that elderly colleagues, particularly tenured employees, lack incentives to engage in DT efforts since they face no professional consequences for refusal (MDCA3). However, this challenge is not limited to elderly colleagues. The lack of incentive is widespread across all age groups. Younger employees in the administration perceive their formal education as sufficient, displaying little interest in further developing their digital skills. (MDCA-M1). The lack of directive authority of the regular MDCAs can generate frustration because the MDCA solely relies on consistent persuasion until resignation (MDCA-M2; MDCA3; MDCA7)

Insufficient visible prioritization. This refers to the quasi-voluntary and resource-constrained set-up of MDCA initiatives, which results in structural marginalization of the MDCA role and reduces their overall effectiveness in the DT. Hence, the overall impact of the MDCAs in their current role within the case city is considered rather limited

by the majority of interviewed people (MDCA5). City-2 reported this challenge, too. Many MDCAs are not acting upon their role since it is "not a priority."

Tab. 2 – Drivers and Challenges for MDCA initiatives and DT in public administration.

Drivers	**Challenges**	
- Building digital capabilities - Dedicated full-time equivalent for digitalization - Proactive employee initiatives - Participatory leadership style - Active communication - (Re-)Building trust - Personal benefit	<u>Organizational</u> - MDCA role ambiguity - Insufficient training - Lack of clear communication - Unclear responsibilities - Resource scarcity	<u>Cultural</u> - Limited proactive engagement of MDCAs - Limited active leadership support <u>Structural</u> - Lack of change and digitalization incentives - Insufficient visible prioritization

5. Discussion

MDCA initiatives are a recent attempt to accelerate DT in public administration. While the literature on DT and change agents in public administration predominantly focuses on managerial change agents in leadership positions and managerial influence, the role and effectiveness of lower-hierarchy internal change agents, such as MDCAs, remain largely underexplored. This gap results in a lack of empirical insights into the effectiveness of such initiatives to enhance DT. This study presents insights into the effectiveness of MDCA initiatives on DT in public administration. To this end, we conducted an exploratory case study with a case city in southern Germany using interviews, informal discussions, document analysis, and insights from another south German city that implemented the same initiative. In the following, we first contextualize the observations with the literature to derive propositions, then present theoretical and practical implications and address the limitations of this study.

5.1 Propositions for Digital Transformation Initiatives in Public Administration

The effectiveness of internal change agents, particularly in the public sector, is underexplored in the literature, with existing research mainly focusing on industrial settings (Bünnagel, 2021; Parry et al., 2014). While clarity for the primary role is recognized as a factor for organizational effectiveness, its impact on employees assuming an additional role – such as MDCAs – has not been systematically examined. Our findings indicate that MDCA role ambiguity contributes to internal and external adoption issues. MDCAs from two initiatives struggled to internalize their responsibilities due to vague expectations. At the same time, colleagues and managers found it difficult to engage with them effectively, as their function within the organization remained unclear. This ambiguity results in uncertainty regarding how MDCAs should contribute to DT efforts, leading to passivity, deferred tasks, and inefficiencies in DT acceleration. In contrast to our results, Fischer and Breaugh (2024) found that MDCAs had a significant effect in their investigated city, deriving by six success factors: 1) The selection of motivated and empathetic MDCAs, 2) the provision of sufficient time resources, 3) the utilization of local expertise, 4) a focus on specific tasks to prevent overload, 5) the integration into broader digitalization strategies, and 6) the recognition and appreciation of their work. As laid out, our case city could only leverage factor 3) using local expertise and touched upon factor 1) selection of motivated MDCAs, and factor 6) appreciation of MDCAs; the remaining factors are neglected with the current set-up of the initiative and thus limit the effect of MDCAs in the case city. In our case study, the case city did not manage to implement an effective MDCA concept, leaving most MDCAs without the necessary structural support to succeed. The main reasons we identified are the MDCA role ambiguity, insufficient training, and the missing structured framework. Insights from City-2 further confirm the above findings, as they also reported unclear role descriptions and misperceptions of MDCAs as low-level IT support due to role unclarities. This leads to:

Proposition 1: Insufficient role definitions and organizational anchoring of MDCA initiatives reduce their effectiveness in accelerating DT because it leads to unclear responsibilities and limited active participation in DT efforts. (MDCA Role Clarity & Anchoring Proposition)

The case study demonstrated how the decentralization of DT responsibilities without accountability or monitoring concepts leads to decreased ownership and limited incentives for managers in DT initiatives. Responsibilities are passed back and forth until they reside on either side without consequences. We observed that public managers struggle to operationalize strategies. This is unsurprising because strategies and their operationalization were not a common and relevant task in public administrations before DT. Traditional public administration training does not emphasize the development of these competencies. This creates ambiguity regarding who is responsible for

DT at various levels, leading to a diffusion of responsibility between departments and hierarchical layers. The lack of communication within the DT exacerbates this effect. With vague responsibility structures, DT risks stagnation, as departments either defer ownership or fail to coordinate efforts effectively. This leads to:

Proposition 2: Unclear operational responsibility and respective monitoring for digital strategy in public administrations diminishes engagement and ownership of DT initiatives, leading to fragmented efforts and reduced long-term impact. (Responsibility Proposition)

Insufficient prioritization of DT efforts in public administration is often reflected not only in financial constraints but also in a significant shortage and allocation of specialized personnel, limiting the resources necessary to drive meaningful change (Fischer & Breaugh, 2024). Eggers and Bellman (2015) found that public administration is often faced with many competing priorities like political agendas, limited funding, or the lack of digital workforce skills, all of which make it harder to prioritize DT. The quasi-voluntary nature and limited visibility of the MDCA initiative contribute to the perception that DT is not a strategic priority in both cities. Additionally, time allocation for internal change agents has been a less examined factor in DT literature. Our results indicate that a quasi-voluntary set-up, without positive or negative incentives, has minimal impact on accelerating DT. Therefore, the formal allocation of resources for MDCAs is essential to ensure their effectiveness. Similar challenges have been reported in City-2, where MDCA responsibilities are frequently deprioritized due to time constraints. This leads to:

Proposition 3: A lack of strategic prioritization of DT in public administrations leads to reduced employee engagement due to perceived misalignment between organizational goals and individual motivation for change. (Prioritization Proposition)

The public sector's unique characteristics, such as monopolistic structures, distinct organizational cultures and demographics, and tenure protections, create structural barriers to DT often overlooked in change agent literature. Unlike private-sector organizations, where market competition and performance incentives drive DT, government institutions lack direct external pressures, and employees face minimal consequences for resisting change. Ritchie (2014) identifies risk aversion, bureaucratic inertia, and a lack of incentives as key factors inhibiting change in government, which enhances a culture where maintaining the status quo is preferable to engaging in innovation. Moreover, accountability for DT initiatives is often unclear, leading to diffusion of responsibility and slow adoption. Findings from our case study align with these observations, particularly in the absence of DT incentives. Employees receive no rewards for engaging in DT nor repercussions for resistance. Consequently, elderly tenured employees show little urgency to join DT activities, which may lead to stagnation. While MDCAs advocate for DT, their lack of directive authority limits their impact. To address these challenges, targeted incentive mechanisms tailored to the public sector are necessary. Options include integrating DT competencies into promotion criteria, creating structured recognition programs, or establishing clearer accountability frameworks. Based on these observations, we propose the following:

Proposition 4: The monopolistic structure and tenure protection of employees in public administration reduce the urgency for DT unless targeted incentives and accountability mechanisms are introduced. (Monopoly & Incentive Proposition)

5.2 Recommendations for MDCA Initiatives in Public Administration

This chapter summarizes actionable recommendations for municipalities that plan to implement or enhance their MDCA initiative based on the lessons from the above investigation.

Solid MDCA concept: To strengthen the effectiveness of MDCAs, a detailed concept with a clear definition of their role and responsibilities is essential. Establishing a catalog of examples or minimum tasks can provide guidance and set clear expectations. Transparent and frequent communication is also critical for successful DT and MDCA initiatives, ensuring adequate information sharing and a unified strategy (Parry et al., 2014). This should include regular internal updates on the MDCA role, tasks, and achievements, such as through newsletters or internal reports. To improve the capabilities of MDCAs, a comprehensive training program tailored for non-specialized change agents should be introduced, focusing on change and resistance management, with a particular focus on the public sector. Training materials should incorporate practical methods like role-playing exercises to enhance applicability and retention. We further recommend regular refresher sessions on emerging technologies and change practices, as many MDCAs struggled to recall or apply the learned concepts. A centrally managed initiative should oversee scheduling, networking, and training opportunities (Winners, 2020). Offering a structured framework could increase engagement and motivation among MDCAs. Furthermore, introducing a low-effort reporting mechanism (e.g., a past activities list) for the Digitalization Department would foster a sense of responsibility. Last, a continuous evaluation through annual surveys could ensure ongoing improvement of the initiative and adaptation to emerging challenges.

Clear assignment of responsibilities: This includes explicit role descriptions for managers and MDCAs, ensuring

that expectations and duties are well-defined. Managers should be held accountable for driving DT within their departments, particularly regarding the operationalization of the digital strategy. To support this, additional training for managers on how to effectively translate strategic goals into concrete actions could enhance their capacity to lead DT efforts successfully.

Visible prioritization of DT in theory and practice: Adequate resource allocation, particularly for the digitalization officer and their department, could enhance DT activities. MDCAs require dedicated time for their responsibilities rather than being expected to fulfill their role alongside their regular duties (Winners, 2020). While limited budgets restrict sufficient public administration, increased funding for the MDCAs should demonstrate a higher priority for the initiative and DT. With more funding, accountability concepts and reporting duties could be justified. In addition to this, regular communication on DT topics and emerging technologies should be aligned with the overall strategy to enhance awareness and engagement. Additionally, incentive structures should be developed within the framework of public administration to encourage participation and commitment.

Leverage organizational and cultural drivers: Leveraging organizational and cultural drivers can significantly enhance DT efforts. Organizational drivers should be prioritized, as they fall within the organization's direct control, allowing for structured implementation. At the same time, cultural drivers should be actively fostered through initiatives such as mentoring programs with successful managers or departments and competitions that encourage engagement. In particular, personal benefit has proven to be a powerful driver, offering a positive incentive for employees to adopt digital processes while mitigating resistance to change.

5.3 Implications and Future Research

This study contributes to the underexplored literature on DT and change management in public administration by examining the effectiveness of MDCA initiatives in a quasi-voluntary setup. While most research on internal change agents focuses on the private context, public administration faces distinct organizational, cultural, and structural challenges that require further theoretical exploration. By identifying key drivers and challenges of MDCA initiatives, we provide empirical insights into their role in accelerating DT and adapting change management strategies to the public administration context. Additionally, while existing research emphasizes change agents in leadership roles, our findings offer a nuanced perspective on regular employees assuming this role, broadening the theoretical discourse on hierarchical and non-hierarchical change-facilitation. The derivation of propositions provides a foundation for future research to empirically validate, refine theoretical frameworks, and develop practical strategies to enhance the effectiveness of DT initiatives in public administration. From a practical perspective, the results offer valuable guidance to cities or other public administrators who have already implemented MDCAs or are planning to do so. They can draw upon actionable drivers and recommendations that facilitate the implementation and help reduce potential inefficiencies in DT. This study comes with limitations. Following a qualitative case study approach limits the generalizability of the findings. Furthermore, the unique legal framework of German public institutions might yield additional bureaucratic hurdles to DT in public administration. Future research could focus on the quantitative evaluation of the MDCA initiatives outside of Germany and innovative accountability concepts suitable for the German public sector context.

6. Conclusion

The DT in public administration remains a complex challenge, requiring municipalities to adapt to evolving technological demands and citizen expectations while maintaining efficient service delivery. This study highlights the effectiveness of MDCA initiatives in facilitating DT efforts, particularly within a quasi-voluntary setup. Our findings reveal that the efficacy of MDCAs is highly dependent on clearly defined roles, sufficient and adequate training, and sufficient resource allocation. While MDCAs can serve as important facilitators of change, unclear responsibilities, insufficient managerial support, and a lack of strategic prioritization significantly limit their impact. Furthermore, our analysis underscores the importance of effective incentive structures and stronger organizational anchoring of MDCA initiatives to enhance their effect on DT. By identifying drivers and challenges, this study contributes to the broader discourse on change management and DT in public administration. Future research should focus on the empirical validation of our proposed theoretical insights to expand the understanding of how internal change agents can be leveraged to accelerate digitalization in government settings.

Track 10: Generative Artificial Intelligence in Government

Track Description

Given the rapidly emerging transformations of Generative AI (GAI), the track aimed to (i) bridge research on potential theoretical underpinnings of generative AI's implications for government, as well as research on practitioners' growing experiences with generative AI in public governance; (ii) critically examine the adoption and impact of GAI in government functions, policies, and public engagement; (iii) in-depth examine associated challenges, ethical considerations, and regulatory and policy frameworks for the expanding applications of GAI in government. Collectively, the papers in this track seek to examine the implications of GAI for transparency, inclusion, accountability, and trust in government. Moreover, the track sought comparative research papers that explored emerging global governance and policy interventions as well as legal and regulatory frameworks for governing generative AI, and research papers contextually examining generative AI applications within diverse geographies, cultural settings, and societal structures.

Abstract. *Context*: The speed of technological advancement has raised concerns about the impact of automation on work. Previous studies have analyzed this impact on the private sector, but there is little research focused on the Brazilian public sector, which faces additional challenges in dealing with this issue. *Objective*: To estimate the impact of automation on intermediate-level federal public positions and indicate professional retraining paths for civil servants, in the face of technological changes. *Methodology*: A 4-step approach was used, involving (1) mapping of automation technologies, (2) extraction and review of the job duties of 142 intermediate-level public positions from a government document with the support of AI models, (3) assessment of the importance level and horizon of automation of each job duty by GPT-4 Turbo and (4) suggestion of professional retraining courses for each position. *Results*: A considerable potential for automation of the analysed positions was identified, with 72% of the job duties with different automation levels in an immediate or short-term impact horizon. However, also considering the frequency and importance of each job duty, a considerable part of the positions had an impact between 0.10-0.28 points on a scale of 0 to 1. The technologies with the most occurrences in the analysis of automation impact were Machine Learning, Smart Sensors and Process Digitization Systems. In the end, 236 professional retraining courses were suggested to better prepare employees for possible technological impacts.

1. Introduction

The speed at which new technologies are created and disseminated has increased over time (Comin & Hobijn, 2010). In the current 4th Industrial Revolution, we have ChatGPT as a recent example of technological diffusion that occurred at an unprecedented speed. In just 5 days, ChatGPT already had more than 1 million users and, in just two months, more than 100 million monthly active users (Reuters, 2023).

Such a fast pace of advancement brings a series of concerns to any organization from a work perspective. The rapid implementation of new technologies requires preparation on the part of employers, government and workers, which, if not done, can lead to problems such as technological unemployment (Lima, Barbosa, et al., 2021). It is important to emphasize that the impacts of these new technologies may affect different population groups in distinct ways, with women and black individuals potentially being the most disadvantaged due to their weaker labor market inclusion.

Over the past decade, a significant amount of research has been devoted to exploring the impact of automation on labor. Despite the volume of articles discussing the risk of unemployment caused by automation, there was no research that considered the distinction between the public and private sectors until 2021 (Adamczyk et al., 2021). As far as the search that was carried out for this research, there are only two articles have focused on the impact of automation on the Brazilian public sector (Adamczyk et al., 2021; De Oliveira Teixeira et al., 2022). Notably, the public sector does not have the flexibility that the private sector has to deal with the impacts of automation in terms of hiring, firing, and reallocating workers (Adamczyk et al., 2021; Banco Interamericano de Desenvolvimento, 2020).

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

This research aims to provide a new and updated estimate of the impact of automation on public sector occupations—an effort made necessary by the current pace of technological innovation and diffusion. It also seeks to go beyond previous studies by identifying professional retraining pathways that can help federal public servants modernize their work activities. The study was conducted over the course of a four-month postdoctoral project in partnership with the Secretariat for People Management of the Ministry of Management and Innovation in Public Services. The analysis presented here is part of a broader set of initiatives led by the Ministry to deliver data-driven insights for decision-making related to the creation, merging, elimination, or enhancement of hundreds of public service careers, as well as the planning and scale of future civil service entrance examinations.

The methodology developed to achieve this goal begins by identifying the main categories of automation technologies expected to impact work in the Brazilian public sector in the coming years. It then involves the use of Claude (a generative AI model similar to ChatGPT) to extract and review the job duties of selected positions. Based on these duties, GPT-4 Turbo—the latest model from OpenAI, the developer of ChatGPT—is employed to assess the potential impact of automation on each position and to recommend professional retraining courses aligned with the required technological updates. While the use of large language models (LLMs) for research purposes is still relatively new and presents several challenges, every step of this study was carefully designed and reviewed by both the research team and the public servants supervising the project. Moreover, the results are presented with appropriate caution, and their application will be subject to human validation and complemented by other methodologies and data sources.

The remainder of this paper is organized as follows. Section 2 presents other research related to the topic of automation, particularly those related to the object of this research, automation in the public sector, and the methodology for assessing the impact of automation. Section 3 presents the methodology of the work in its four stages and highlights important differences between the present study and previous ones. Section 4 has four parts, one for each stage of the methodology, and presents the categories of technologies found during the technological mapping, the result of the extraction and review of the job duties of the selected public positions, the results of the assessment of the impact of automation on the positions and the results of the process of proposing professional retraining courses in view of the identified impact. Section 5 concludes the paper by bringing some final remarks, limitations of the work and perspectives for future work

2. Literature review

The analysis of the impact of automation gained traction in 2013, when the seminal article by Frey and Osborne was published, still as a preprint, assessing how susceptible jobs in the US were to computerization[1] (Frey & Osborne, 2017b). Since then, the article has received more than 13,000 citations and has been applied in the context of several countries around the world (Brookfield Institute, 2016; Deloitte, 2015a, 2015b; Santos et al., 2015; World Bank Group, 2016), including Brazil itself. In the Brazilian case, 60% of the workforce would have a high probability of being automated, and the same correlation between level of education and the impact of automation was observed, with the correlation between wages and the impact of automation existing, but weak (Lima, Strauch, et al., 2021).

Specifically on the impact of automation on Brazilian public sector employees and their occupations, there are two recent studies that should be mentioned (Adamczyk et al., 2021; De Oliveira Teixeira et al., 2022). The first of these studies was carried out in 2021 by researchers from PUC-RS, ENAP, IDP-DF and CNPq and had as its object of analysis federal government employees (Adamczyk et al., 2021). In this study, the Bartik Occupational Tasks (BOT) method was applied, which involves separating the differential effects of automation from the national and structural effects that lead to local employment growth, and then analyzing the frequency of words in the activities of the occupations associated with the differential effects of automation. Natural Language Processing and Machine Learning algorithms were used to extract quantitative information from the descriptions of work activities in the Brazilian Classification of Occupations (CBO). In total, 521,701 public servants distributed across 389 positions were analyzed. As a result, this first study showed that 20% of federal public servants are in occupations that are highly susceptible to automation in the next decade. Here again, it was observed that occupations related to lower levels of education and lower wage levels are more representative among those with a greater chance of being automated.

The second study was conducted in 2022 by researchers from BIOTIC and IDP, and analyzed the public sector of the Federal District (De Oliveira Teixeira et al., 2022). The methodology adopted in this study was based on another study by researchers from IPEA that considered the importance and relevance of the activities performed by each occupation (according to the O*NET occupation database in the USA) by analyzing the frequency of words related or not to automation (Kubota & Maciente, 2019). Based on the results of this study, a correlation was made between

[1]Computerization, according to the authors, would be the automation caused by Computing technologies, in particular, Machine Learning and Mobile Robotics.

the positions and duties of the executive branch of the Federal District Government and the occupations analyzed by IPEA researchers to arrive at an estimate of the impact of automation on the public servants analyzed. As a result, of the almost 100,000 civil servants who occupied the 368 positions analyzed, 5.5% were at high risk of automation, 24.1% at medium risk, and 70.4% at low risk (Kubota & Maciente, 2019). In this study, the positions that required a lower level of education were also those with the highest risk of automation.

The launch of ChatGPT by OpenAI in November 2022 and its use by more than 100 million active users as of January 2023, a record (Reuters, 2023), has made AI a versatile and user-friendly tool for workers in a wide range of sectors. The potential of this technology to impact work has led to a new wave of research on the impact of Generative AI (Chui et al., 2023; Eisfeldt et al., 2023; Eloundou et al., 2023; Gmyrek et al., 2023; Noy & Zhang, 2023), the technology category to which ChatGPT belongs. Some of this new research has brought with it an important innovation to automation studies, which is the use of Generative AI itself in the impact assessment process (Eloundou et al., 2023; Gmyrek et al., 2023).

In the first study published using this methodology, researchers from OpenAI itself analyzed the impact that technologies such as Generative Pre-trained Transformers (GPTs), that is behind ChatGPT, would have on the US workforce. The authors prompted GPT-4 to evaluate a set of occupations based on the descriptions of their activities according to the degree of exposure to GPTs at three levels: E0, in case of no exposure or worsening of the result in case of adoption of the technology; E1, direct exposure, when ChatGPT would reduce the execution time of the activity by 50%; and E3, when access to ChatGPT was not enough, but software developed based on GPTs were able to reduce the execution time of the activity by 50%. As a result, the authors paper that 80% of the US workforce would have at least 10% of their activities impacted by GPTs, while 19% of the workforce would have at least 50% of their activities impacted by this technology. An important result that contrasts with the aforementioned research, carried out before the emergence of ChatGPT, is that the effects of GPTs span all salary levels, with higher-paying jobs potentially facing greater exposure (Eloundou et al., 2023).

It is worth noting that the impacts analyzed by the studies cited do not cancel out those found in studies from the last 10 years, but rather add to the previous ones. Thus, it is becoming increasingly difficult to identify any occupation or economic sector that is immune to the impact of automation technologies of the current 4th Industrial Revolution.

Another important recent study that used ChatGPT was the one carried out by the International Labour Organization (ILO), which also sought to understand the impact of GPTs on employment, in this case, at a global level. The authors used the International Uniform Classification of Occupations (ISCO-08) as a basis to analyze the 436 occupations described therein. Before assessing the impact of GPTs themselves, the authors asked GPT-4 to generate a definition and list of 10 activities for each of the occupations and ISCO-08 codes provided. Based on this list of activities and occupations, the authors proceeded to ask GPT-4 to evaluate each one on a range from 0 to 1 according to the degree of automation of the tasks if GPT were adopted (Gmyrek et al., 2023).

In the study presented, it is identified that five categories of tasks are significantly impacted, with an impact greater than 0.75: administration and communication, customer service, data and records management and maintenance, information processing, and language and information provision services. It was found that, among the occupational groups, the "Administrative and Office Support" sector is the most affected, with 24% of tasks highly susceptible to automation and 58% with medium susceptibility. In comparison, in other occupational groups, the proportion of highly vulnerable tasks varies from 1% to 4%, and those with medium exposure do not exceed 25%. Finally, the influence of automation on employment differs significantly between countries of different income levels, due to their distinct occupational structures. In low-income nations, only 0.4% of total employment is at risk of automation, while in high-income countries, this number increases to 5.5% (Gmyrek et al., 2023).

In addition to these international studies, research conducted in Brazil provides further insight into the potential impact of automation on the country's labor market. Kubota and Maciente (2019) analyzed the susceptibility of occupations in the formal sector to automation, utilizing a methodology that classified jobs based on the degree of automatability of their tasks. Their findings indicate that 56.6% of formal employment in Brazil consists of occupations with a high or medium-high percentage of automatable tasks. This study also highlights that while some occupations traditionally considered at risk, such as bank tellers and telephone operators, have seen employment decline, others with high automation potential—such as administrative roles—continue to grow. This suggests that the diffusion of new technologies may impact not only declining occupations but also those that have played a significant role in recent job creation.

Furthermore, the study underscores the regional and sectoral differences in automation susceptibility. Urban centers, particularly metropolitan regions, tend to have a lower share of highly automatable occupations (around 36% of formal employment), whereas smaller and more economically isolated municipalities exhibit a higher concentration of automatable jobs, particularly in transportation and logistics. From a sectoral perspective, the highest risks are observed in industries such as textiles, food production, wood processing, and metallurgy, as well

as in certain service sectors like accounting, cleaning services, and logistics. This reinforces the need for policy interventions aimed at workforce reskilling and adaptation, especially in sectors and regions most vulnerable to automation-driven labor displacement.

In order to contribute to this field of research and provide data to support public policies, this research aims to analyze the impact of automation on a set of positions in the Brazilian public sector, as has been done before (Adamczyk et al., 2021; De Oliveira Teixeira et al., 2022), but using technologies such as ChatGPT, like more recent research on the subject (Eloundou et al., 2023; Gmyrek et al., 2023). In addition to defining automation levels for each position, the research presented here also seeks to indicate professional retraining paths for the positions analyzed. Further details on the methodological differences between this work and previous ones will be provided in the next Section on methodology.

3. Methodology

In order to estimate the impact of automation on public positions and indicate professional retraining courses, the methodology presented in Figure 1 was developed and used in this research. Each of these steps generated a product that can be considered a contribution of this research to the academic community and to Brazilian public management[2]. The methodology made extensive use of the most advanced and capable LLM models available at the time of execution of each step..

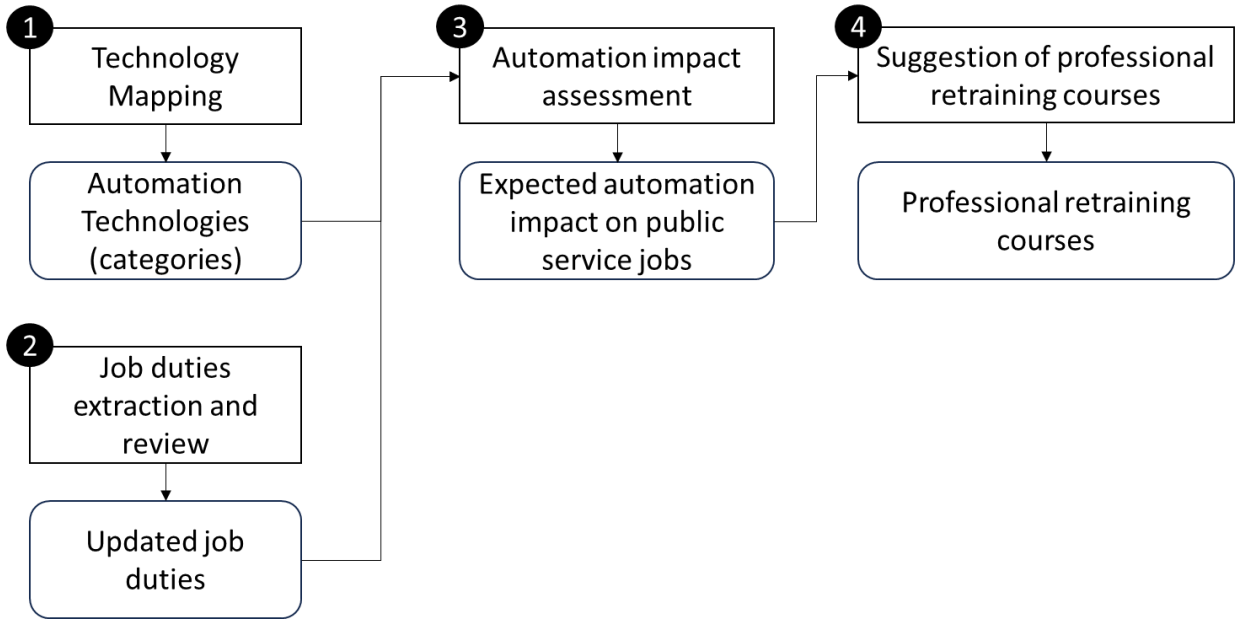

Figure 1: Summary of research methodology. Source: Created by the authors.

The assessment of the impact of automation on public jobs depends on two inputs: a list of automation technologies that are expected to impact the sector in the coming years and some type of job description that allows for a detailed analysis of the job. The first of these inputs is produced through a technology mapping based on the literature published in the last 2 years. The list of technology categories resulting from this process is then analyzed using ChatGPT 4 and Claude 2 to decide which are in fact categories of automation technologies and would have some impact on the job. Finally, ChatGPT 4 is used to provide a brief definition for each technology category and indicate 5 technologies that would be related to each one. The results of this first stage of the methodology are presented in Section 4.1.

To produce the second input required to assess the impact of automation, the job duties of the public positions to be analyzed were extracted and reviewed. As highlighted by previous research, there are a number of challenges in analyzing the positions and job duties of the Brazilian public sector given the lack of standardization in terms of code, name, and description, as indicated by previous studies (Adamczyk et al., 2021; De Oliveira Teixeira et al., 2022). In the case of the present research, an alignment of priorities was made with the Secretariat of Human Resources and the Secretariat of Labor Relations of the Ministry of Management and Innovation in Public Services (MGI) to decide which positions would be most relevant to be analyzed and which had some documentation that

[2] The prompts, codes and data produced during this research can be found at: https://drive.google.com/drive/folders/1kYqUzCRbaFB3YpfJij8KSOeiy-5thLr-?usp=sharing

gathered the job descriptions. With this, it was decided that the focus would be the analysis of intermediate-level (IL) positions and their job duties that are included in the Career Plan for Technical-Administrative Positions in Education (PCCTAE, in portuguese). The PCCTAE is a document published by the Federal Government, as part of Law No. 7.596 of 1987, that contains a list of 340 positions, of which 142 are intermediate level, and their responsibilities. It is important to note that some of these 142 positions exist in other agencies that are not in the education sector, which broadens the scope of the research.

The extraction and review of the job duties of the selected positions was done following the steps presented in Figure 2. The extraction was done using a Python code that processed the PCCTAE (pdf) file and generated a spreadsheet with the positions and their respective job duties. Then, another Python code sent the positions and job duties from the spreadsheet along with a prompt that asked the GPT-4 API to perform four activities. First, for each of the positions, GPT-4 should analyze the list of job duties provided and remove those that were considered obsolete, given that the list was written in 1987. Next, GPT-4 should expand or reduce the list of job duties for each position so that there would be a standardized number of 8 activities per position [3]. To record what GPT-4 did with the job duties for each position, it was asked to record whether each activity was: original, if the proposed job duty was the same as an activity in the original list; updated, if the proposed job duty was already on the original list, but something has been changed in the activity text; new, if the proposed job duty was created and was not on the original list. In the third activity, GPT-4 evaluated each job duty in terms of the frequency with which an average worker would perform each one, according to the scale below: rarely, once a year or less; occasionally, a few times a year, less than once a month; monthly, at least once a month, less than once a week; weekly, at least once a week, less than once a day; and daily, once or more times a day.

Finally, the last activity performed by GPT-4 was to define the degree of importance of each duty for the related position according to the scale: very low, low, medium, high and very high. The definition of frequency and degree of importance for each activity aimed to qualify the impact of automation, given that a high impact may be of little relevance for an activity that is rarely performed and of little importance for a given position. This type of classification is done by workers in catalogs of occupations and activities such as the one that exists in the USA (O*NET) and has not been used in previous studies, given the cost of producing something of this type for Brazil. However, GPT-4's ability to analyze data on occupations, proven in other previous studies, can be applied to enrich the analysis of the impact of automation by providing estimates for the frequency and degree of importance of the duties of the positions. The results of this step are presented in Section 4.2.

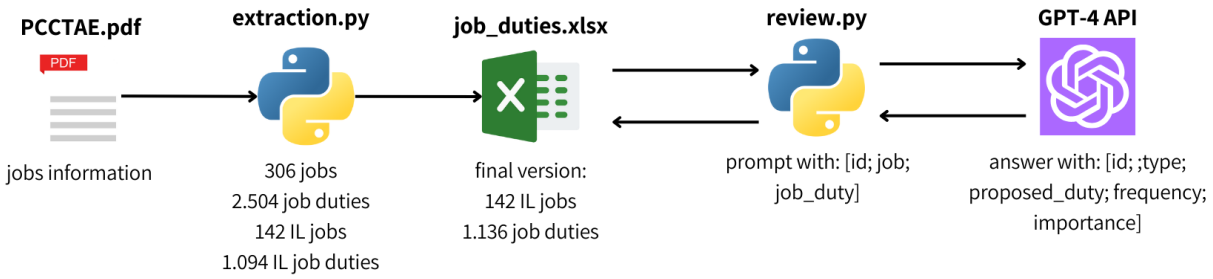

Figure 2: Details of the stage of extraction and review of public office duties. Source: Created by the authors.

Continuing with the research methodology, step 3 was the assessment of the impact of automation on the selected job roles (Figure 3). Here, a prompt (Appendix 2) for the GPT-4 Turbo API was developed with the categories of automation technologies, their descriptions, and related technologies resulting from step 1 of the methodology, and the job roles and duties resulting from step 2. In this prompt, GPT-4 Turbo was asked to respond with:

- A level of automation, according to the scale: Full (90-100%), High (70-80%), Medium (40-60%), Low (20-30%) and None (0-10%);
- Up to 3 categories of technologies and their respective technologies that would be used to automate attribution;
- An automation horizon, according to scale: immediate, available technologies could be adopted to perform the job duty; short term, in up to 2 years we would have technologies ready to replace the job duty;

[3]There is no ideal number of duties that a position should have, but the original PCCTAE list has a large variation in the number of duties, ranging from 2 to 29 duties. On average, there are 8 duties per position, and this number was adopted as being reasonable for standardizing the list.

medium term, it should take between 2 and 5 years for us to have technologies ready to replace the job duty; long term, it should take more than 5 years for us to have the technologies needed to replace the job duty.

To make it easier to understand the assessment made by GPT-4 Turbo, the prompt also asked for a justification for each of the above responses. In addition to helping to understand the logic behind GPT-4 Turbo's response, asking for a justification forces the model to "think" more carefully about its response. The results of this step are presented in Section 4.3.

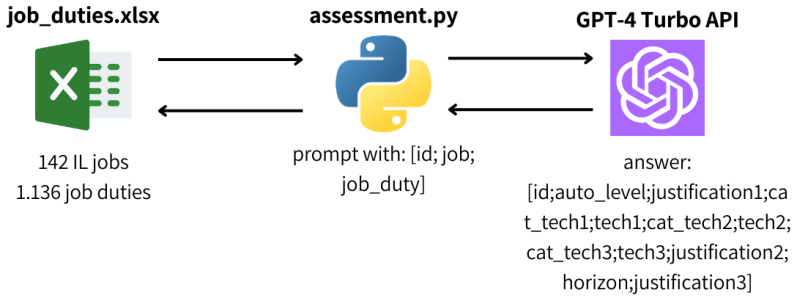

Figure 3: Details of the automation impact assessment stage. Source: Created by the authors.

The fourth and final stage of the research methodology involves suggesting courses for each position according to the duties and technologies related to each one. To do this, the GPT-4 Turbo API was once again called (Figure 4). This time, the prompt received as a response a list of courses, workload and syllabus for each position according to the duties and technologies related to each one. The results of this stage are presented in Section 4.4.

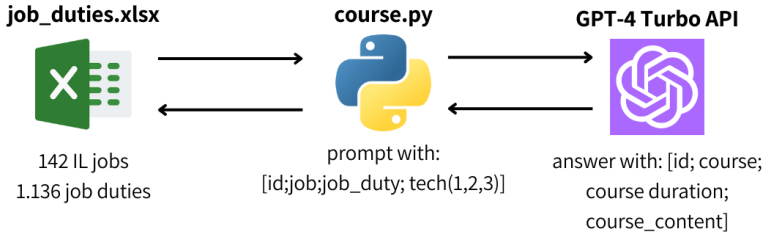

Figure 4: Details of the stage of suggesting professional retraining coursesThe use of footnotes should be avoided. Source: Created by the authors.

4. Results

This Section is structured to present the results of each of the stages of the methodology. Each of the stages generated products that are fully available in the research repository and are presented here to exemplify the results or analyze them quantitatively. Section 4.1 presents the results of the technological mapping, Section 4.2 presents the results of the extraction and review of the job duties of the positions analyzed, Section 4.3 presents the results of the technological assessment, and Section 4.4 presents the results of the suggestion of professional retraining courses.

4.1 Technological mapping

The literature review for the technology mapping was conducted based on technical papers published by organizations such as the World Economic Forum (WEF) and major consulting firms such as McKinsey, Deloitte and Gartner, which produce annual or biannual papers on technology trends. Given the differences in the names of technologies that exist from one paper to another, the list of technologies created from the mapping seeks to bring together, whenever possible, very similar technologies that have been named differently.

After listing all the technologies found in the papers, ChatGPT 4 and Claude 2 were asked to indicate which of them are automation technologies, given that some, such as Web 3, do not directly replace human labor, despite serving as a basis for the development of other technologies. Table 1 presents the result of this process.

The results were then reviewed by a human to ensure that no technology was left out and that the final list did not include technologies that did not belong to the automation technology category. As a result, encryption and cybersecurity technologies, synthetic data, and compression models that had been included by ChatGPT 4 were removed, but after stressing this with the model, the model itself recognized that it did not make sense to include

them. In addition, digital applications and platforms and data analysis were included in the list due to their potential to replace duties and streamline processes. With the final list of automation technologies, some technologies were consolidated into technology categories so that they all had the same level of granularity.

In the last step of this process, ChatGPT was asked to write a brief description and list 5 automation technologies (avoiding overlap and repetition) related to each technology category that should be considered in a study on the impact of automation on work. This led to the final list of automation technology categories which included: Data Analytics, Digital Applications and Platforms, Applied AI, 3D Printing, Internet of Things, Robots, and Extended Reality.

4.2 Extraction and review of job duties

The process of extracting PCCTAE job duties resulted in a list with 142 intermediate-level positions and their 1,093 related job duties that were reviewed by GPT-4 to analyze obsolescence, given that the original document is from 1987, and to include information regarding the frequency of execution of the job duties and their importance. Table 2 shows the response given by GPT-4 for the driver position. In this case, GPT-4 kept 3 of the original job duties, updated one of them, only changing the text to simplify it, and included four new job duties to reach a total of 8, as requested in the prompt. The frequencies and degree of importance of each of the job duties were included so that it is possible to differentiate those that would have the greatest impact on the position in the event of automation.

Table 2: Example of a review of duties for the position of driver. Source: Created by the authors.

Job duty	**Type**	**Frequency**	**Degree of importance**
Use navigation system and route planning	New	Daily	Very important
Test the brakes and electrical system	Original	Monthly	Extremely important
Drive the vehicle	Original	Daily	Extremely important
Arrange for vehicle maintenance	Updated	Occasionally	Very important
Perform emergency repairs to the vehicle	Original	Rarely	Moderately important
Record mileage and fuel consumption	New	Weekly	Moderately important
Check and maintain safety equipment	New	Monthly	Extremely important
Perform daily inspections and safety checks on the vehicle	New	Daily	Very important

Figure 5 shows the distributions of type, frequency and degree of importance resulting from the review process, which resulted in 1,136 job duties. It is possible to see that GPT-4 kept just over 33% of the original job duties, either as they were already written (22%) or updated (11%), with the rest being new. Regarding the frequency distribution, 96% were considered to be performed weekly (45%) or monthly (41%), with only 0.1% of the job duties being rarely performed. Finally, the degree of importance most associated with the job duties was very important, with 52%, followed by moderate, with 30%, and extremely, with 17%. As GPT-4 reviewed the list of job duties and asked to prioritize those that were truly important, none of them received a degree of no importance and only 0.3% were considered somewhat important (low).

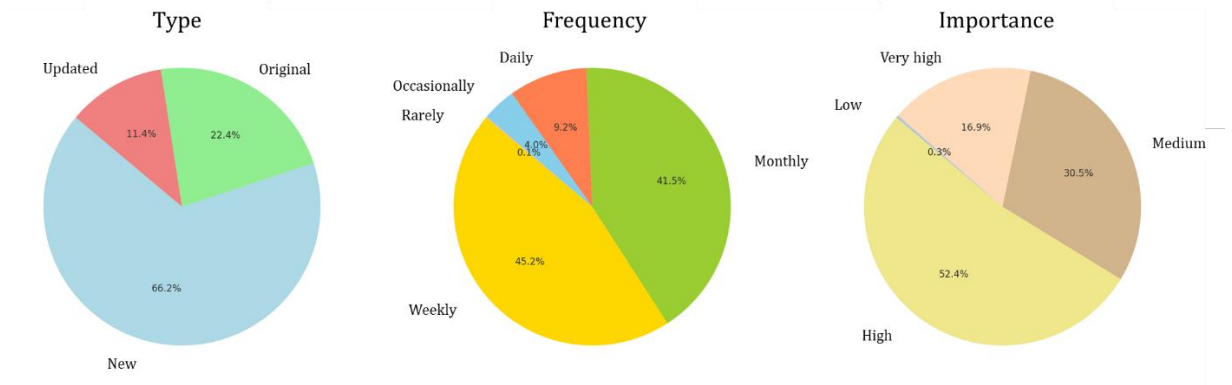

Figure 5: Type, frequency and importance distributions of revised job duties. Source: Created by the authors.

4.3 Assessment of the impact of automation

The automation impact assessment process, carried out with GPT-4 Turbo, resulted in a large amount of information regarding the level of automation, the technology and technology categories and the automation horizon for each of the 1,136 job duties, in addition to the justification for the responses given.

The example below show how the automation impact assessment was done for one job duty.

Position: Props

Job duty: Assemble, transform or duplicate scenographic or costume objects

- Automation level: Medium (40-60%)
    - Rationale: Automation can help with the assembly and duplication of objects
- Technology categories: 3D Printing and Extended Reality
- Technologies: Metal 3D Printer and Augmented Reality (AR)
    - Rationale: 3D printing for three-dimensional objects. AR for visualization and precise adjustments during creation
- Horizon: Short term (< 2 years)
    - Rationale: Advanced 3D printing and AR technologies are still under development for use in stage design

The evaluation exemplified above was made for the 1,136 job duties, with the most frequent level of automation being medium with 507 (44%) job duties, followed by high (295 or 26%) and low (291 or 25%) who had practically the same number of job duties (Figure 6). Less than 4% of the job duties were in the “none” (37) and “total” (6) levels.

Regarding the automation horizon, 817 (72%) job duties were between immediate (411) and short-term (406), 250 had a medium-term horizon and 69 had a long-term horizon (Figure 7).

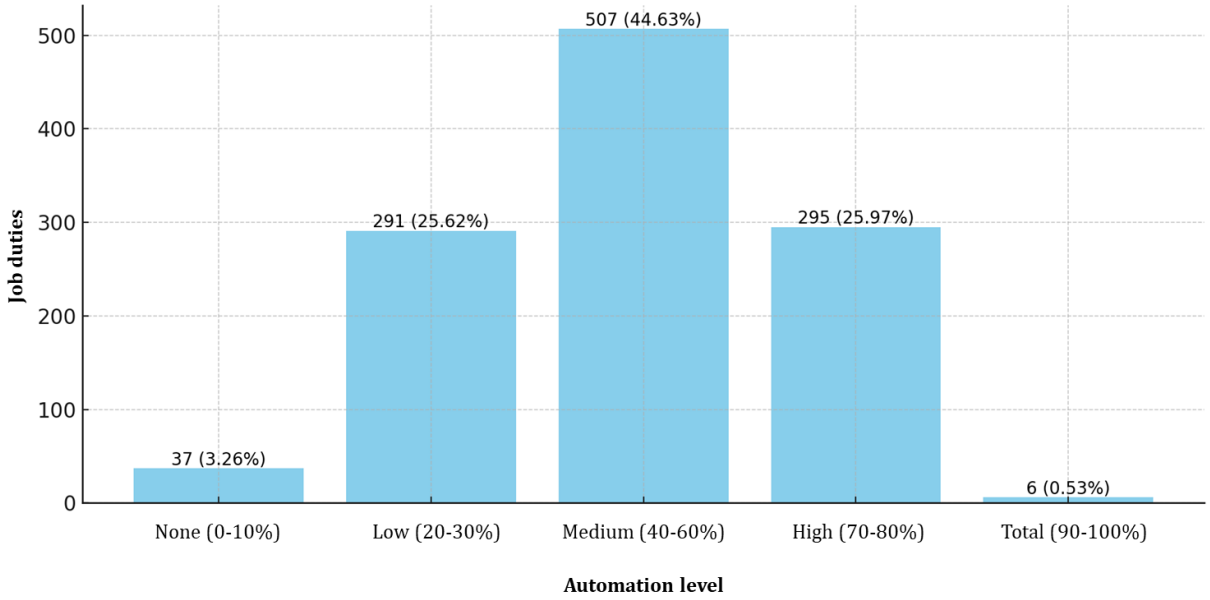

Figure 6: Job duties' automation level. Source: Created by the authors.

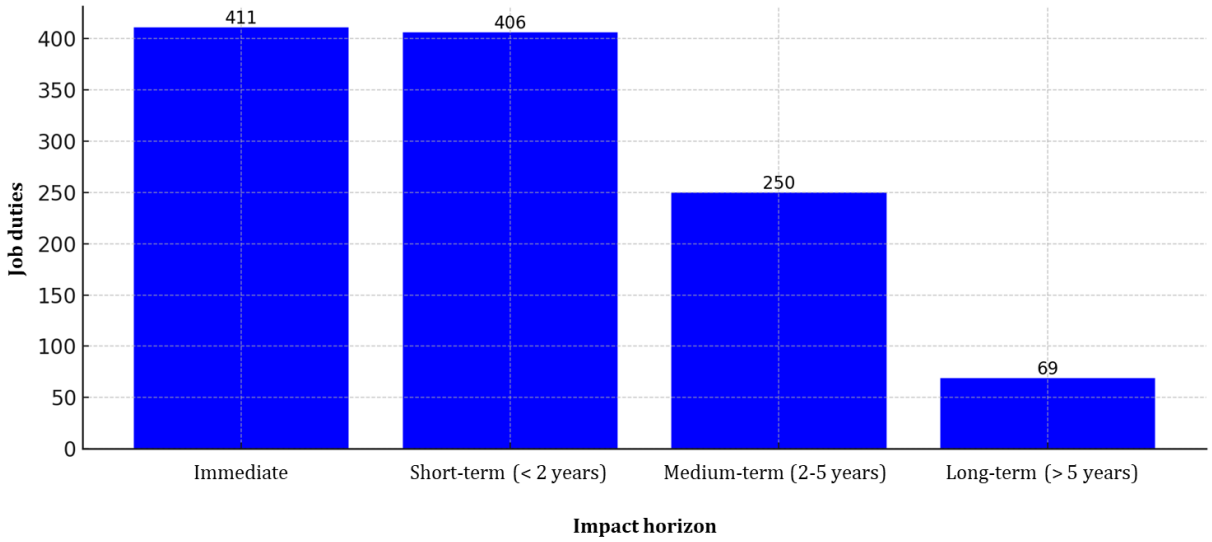

Figure 7: Technologies' impact horizon. Source: Created by the authors.

The calculation of normalized impact (In) for each position was made using the following formula:

$$In = \frac{\sum f \; x \; imp \; x \; lev_{auto} \; x \; hor}{\frac{400}{8}}$$

Being:

f the frequency of job duty

imp the degree of importance of the job duty

lev_{auto} the level of automation of the job duty

hor the horizon of attribution automation

It is important to highlight that the variable frequency of the job duty can assume the following categories and associated values: rarely (1), occasionally (2), monthly (3), weekly (4), and daily (5). Meanwhile, the variable importance of the job duty can assume these values: very low (1), low (2), medium (3), high (4) and very high (5). Automation level, in its turn, ranges from none (0) to total (4). Finally, horizon is scored from immediate (4) to long-term (1). As such, the product of these variables can reach a maximum value of 400, which justifies the division by 400 to normalize the result. Finally, the normalized sum is divided by 8, corresponding to the number of job duties evaluated per position, resulting in the average impact score for that position.

From this calculation, we have the percentage distribution presented in Figure 8, which divides the values *In* found in the assessment into 10 groups. We can see that the maximum impact we have is in the range of 0.47 to 0.52, with less than 1% of the positions, on a scale that can reach up to 1, if frequency, importance, level of automation and horizon are all at the maximum levels. The largest number of positions is in the range of 0.24-0.28, followed by the previous ranges, 0.19-0.24 and 0.15-0.19. Figure 9 and Figure 10 show the 10 positions with the highest and lowest values *In* found in the assessment.

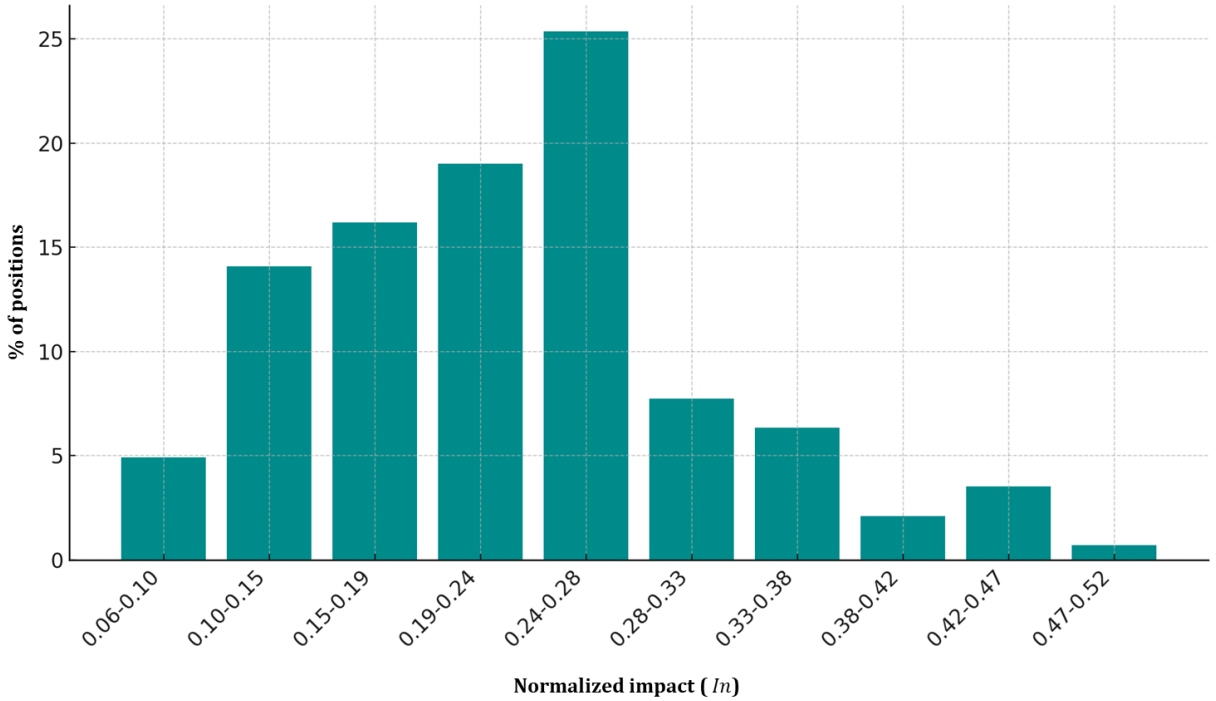

Figure 8: Percentage distribution of positions by impact range of the normalized impact. Source: Created by the authors.

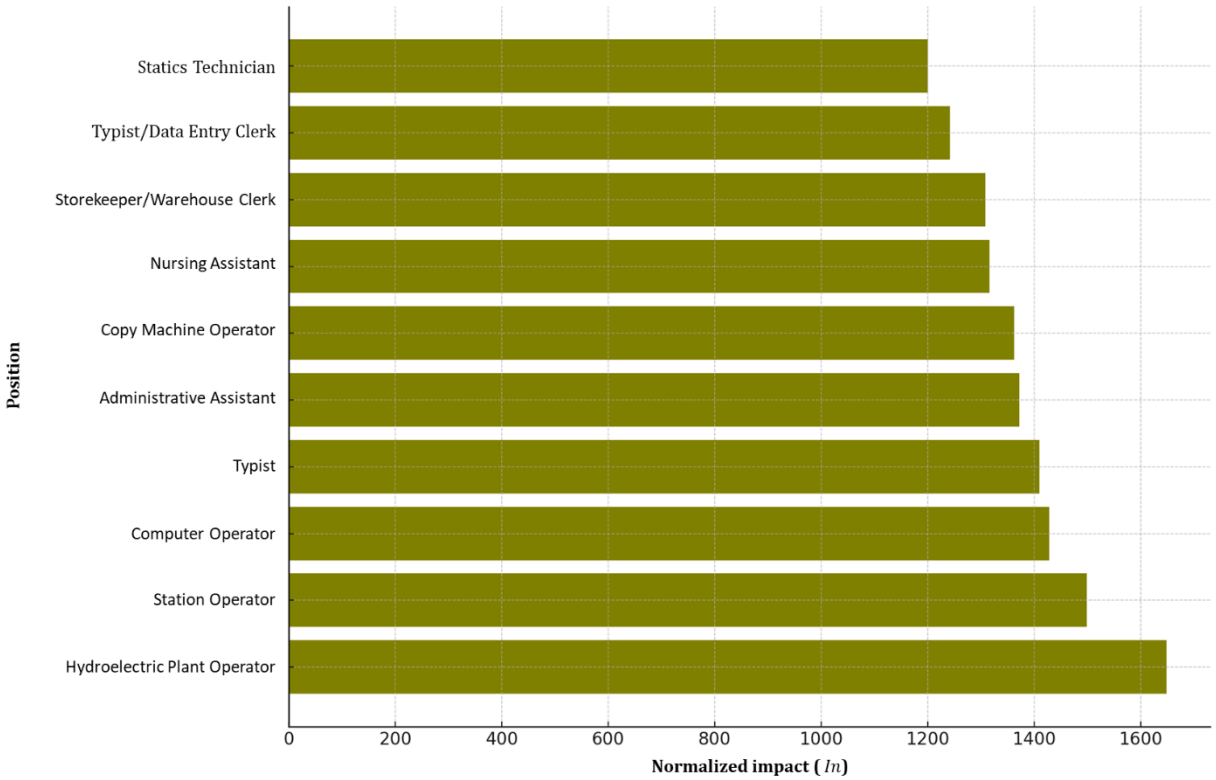

Figure 9: Top 10 positions with the highest normalized impact. Source: Created by the authors.

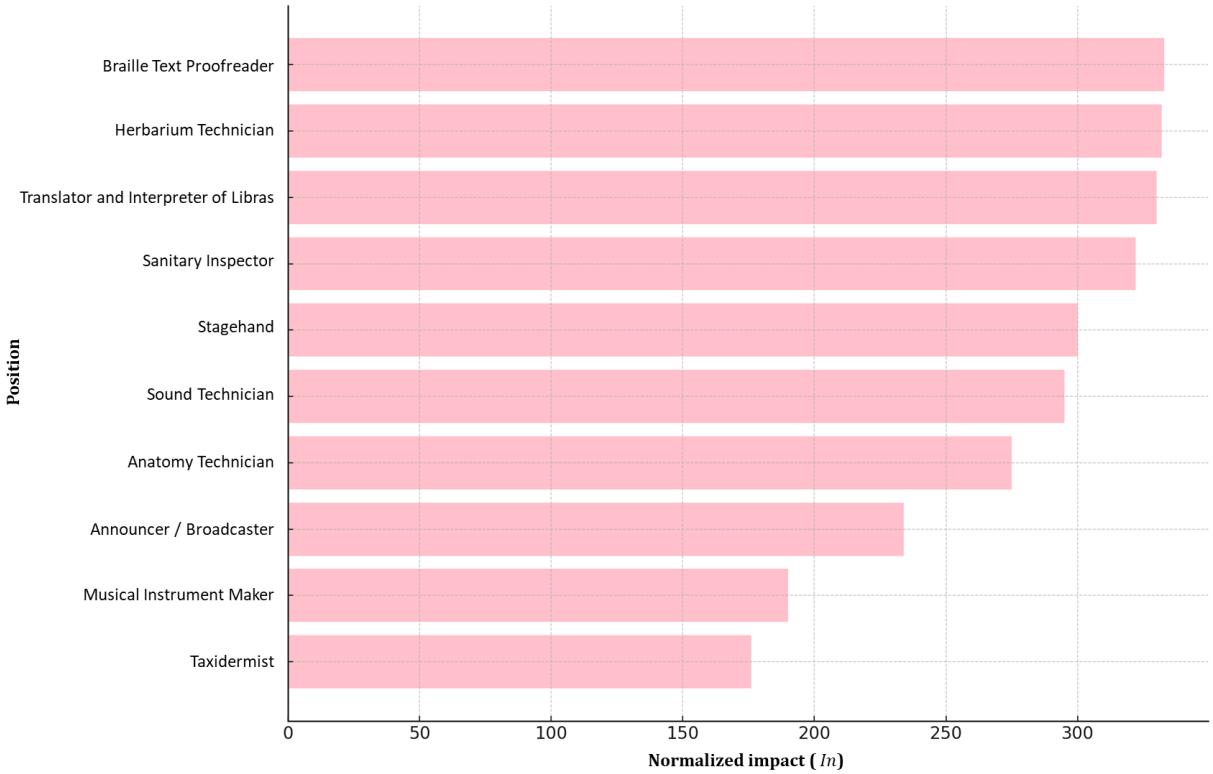

Figure 10: Top 10 positions with the lowest normalized impact. Source: Created by the authors.

Finally, the technology categories that appeared most frequently in the assessment of the impact of automation were Applied Artificial Intelligence (AAI) with 600 occurrences, Digital Applications and Platforms (APP) with 452 occurrences, and Data Analytics (DA) with 382 occurrences (Figure 11). The least cited category was 3D Printing (PRT), with only 25 occurrences. In total, GPT-4 Turbo associated 59 technologies with the 1,136 job duties evaluated (Table 3). Considering that 35 technology examples were given, 5 per category, GPT-4 Turbo needed to suggest 24 more technologies to evaluate all job duties. The list below shows the 10 most cited technologies:

1. Machine Learning: 323 occurrences
2. Smart Sensors: 169 occurrences
3. Process Digitization Systems: 163 occurrences
4. Online Communication and Collaboration Platforms: 104 occurrences
5. Business Intelligence (BI): 100 occurrences
6. Natural Language Processing (NLP): 100 occurrences
7. Data Mining: 93 occurrences
8. Big Data Analytics: 82 occurrences
9. Task and Project Management Systems: 77 occurrences
10. Robotic Process Automation (RPA): 64 occurrences

4.4 Suggestion of retraining courses

The last step of the methodology was the suggestion of retraining courses, which resulted in 236 courses for the 141 positions analyzed. Each course is accompanied by a list of topics and a suggested workload. The example presented in Table 4 for the Props position illustrates the results of this course suggestion process that was carried out with GPT-4 Turbo.

Table 4: Example of suggested courses for the position of Props Specialist. Source: Created by the authors.

Course	**Topics**	**Duration (in hours)**
3D Metal Printing Props Design and Manufacturing Course	Prop Design Fundamentals, Metal 3D Printing Materials and Techniques, Metal Post-Processing Processes for Props.	120

5. Conclusion

Assessing the impact of automation is not new in academia, including scenarios outlined for Brazil. However, few studies have addressed the specific case of automation in the public sector. The challenges in dealing with this issue in public management are even greater than those faced by the private sector and include barriers to creating or eliminating positions. In this sense, it is essential not only to frequently assess the impact of automation on public positions, given the rapid technological advances and the benefits this brings to the services provided to the population, but also to observe possibilities for professional retraining for public servants.

In this sense, the present study seeks to meet these two demands through the use of a modern methodology for assessing the impact of automation that uses Generative AI technologies such as Claude 2 and GPT-4 Turbo to evaluate a large and diverse number of positions quickly and that allows easy reproduction for other cases.

In addition to the methodology itself, the study provides some intermediate results that are contributions in themselves. The technological mapping of recent literature on emerging technologies allowed us to map, define and exemplify 7 categories of automation technologies that are important for the public sector to monitor, given their potential for implementation in a wide range of areas. The extraction and review of the job duties allowed us to create a new list of job duties for public positions that were defined in 1987. In addition, the frequency and degree of importance of the 1,136 job duties resulting from this process gave a degree of detail to the study and

enriched the definitions of the positions analyzed.

The main results of the study involved assessing the impact of automation and suggesting professional retraining courses. The assessment produced a wide range of information that allows us to understand both the level of automation of each job duty and position and a breakdown of this impact with each related technology, an automation horizon and justifications for each of these elements. The level of automation of the job duties was concentrated in the low, medium and high impact range, while the horizon is much more immediate and short term, demonstrating great potential for automation of the intermediate level positions that were analyzed. Despite this potential, when compared with the frequency, the degree of importance and the automation horizon itself, it was possible to see that the positions are concentrated in a range of 0.10-0.28 points out of a maximum of 1 and that no position exceeds 0.52 points. In terms of technologies, the ones that stood out the most were Machine Learning, Intelligent Sensors and Process Digitization Systems, with the most cited technology category being Applied Artificial Intelligence.

The suggestion of professional retraining courses was a new process for the literature in the area, but essential for dealing with automation in the public sector given the limitations of personnel management that exist in this area. 236 courses were generated with their respective syllabuses and workload.

The limitations of this study include those inherent to the technologies used, such as the hallucinations that Claude 2 and ChatGPT/GPT-4 sometimes demonstrate, and the data limitations of the training databases. The GPT-4 Turbo model represents an evolution in the face of these limitations and produced satisfactory results throughout the study, which were manually reviewed to ensure the quality of the final products. The tendency is for these models to evolve in the future and continue to surprise us with their potential for application in studies related to the impact of automation. Furthermore, the study is based on a list of duties that was developed in 1987 and updated for 2023. This process may mask a possibly greater impact of automation given that it is not known exactly what the real duties of public servants who occupy the positions analyzed are in 2023. Thus, this study, as well as any other that deals with a large number of positions or occupations, requires analyses at the individual level of the occupation or of a set of similar occupations that allow us to understand the organization of work in order to bring the analysis closer to the reality of public positions.

Future studies can expand the analysis presented here to other positions in the public sector, as well as develop methodologies that allow for a more in-depth process of suggesting retraining courses to support the creation of complete courses with a description of empirical and theoretical approaches at the forefront of science and a suggestion for the application of contextualized active methodologies. In addition, the technologies applied in this research can be used to help public servants better explore how to use automation technologies as allies in the process of delivering public services with better quality and efficiency.

Finally, as a future research agenda, the aim is to assess the impact of automation considering the criteria of gender, race, and their intersectionality. In a racist and sexist country like Brazil, where the composition of the public sector is still not representative of the population, it is essential to analyze automation through these social markers and critically examine its differentiated effects.

Abstract. In the context of Brazil's re-democratization and the need for greater transparency in public administration, the 1988 Constitution established the right to access public information. However, the complexity of legal language, particularly in court documents, poses a significant barrier to understanding for the general public, especially given that only about 25% of Brazilians aged 25 or older have completed or are pursuing higher education. This study addresses this issue by leveraging generative AI models to simplify legal texts from the Court of Accounts of Pernambuco into plain language, making them more accessible to individuals with a high school education level. The research evaluates the effectiveness of two Large Language Models (GPT and Gemini) and five prompt techniques (Tree of Thought, COSTAR, Zero Shot, One Shot, and Meta Prompting) in producing simplified versions of 14 preliminary decisions. A total of 140 simplified texts were generated and evaluated using an 18-question questionnaire based on plain language principles, with scores generated by AI models and validated through human review. The results show that Gemini with the Tree of Thought technique achieved the highest average score (67.64), based on responses to the plain language questionnaire, while GPT with the COSTAR technique performed best in preserving essential information and achieving the highest readability scores (Flesch Reading Ease: 55.26). However, omissions of critical information were a common issue across all models, highlighting the need for human oversight. The study also found that GPT outperformed Gemini in evaluation accuracy, with lower Mean Absolute Error (MAE) and Mean Absolute Percentage Error (MAPE) compared to human evaluations. Despite this, AI models tended to overestimate readability and comprehension, underscoring the importance of a hybrid approach that combines AI-generated assessments with human review. The findings demonstrate the potential of generative AI to reduce costs and improve accessibility to legal and governmental documents, while also emphasizing the need for further research to address limitations such as omissions, biases, and ethical considerations. This study contributes to the growing body of literature on AI-assisted text simplification and provides a foundation for future work in this area.

1. Introduction

Simplifying public documents for better citizen understanding is a global objective (Petelin, 2010). In 1988, the text of the Brazilian Constitution was enacted. In the context of the country's re-democratization, it became

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

necessary to add subparagraph XXXIII to Article 5, aiming to allow any person to access public agency information, with the goal of increasing transparency and citizen participation in public administration—activities that bring various benefits to society(Andersen, 2009). However, it was only in 2011 that the country began to intensify actions within this agenda, joining the Open Government Partnership (OGP) and, in the same year, publishing the Access to Information Law (LAI) — Law No. 12,527 — which regulates the constitutional provision and outlines the procedures and deadlines for accessing information.

Thus, various Brazilian institutions have started publishing their information on open data online portals, making it accessible to the entire society. However, as these institutions operate in different fields, they use linguistic variations with varying levels of complexity. Among those with a high degree of linguistic complexity are the courts, making it difficult for people who are not regularly immersed in the technical context of the judiciary to understand this information (Belém, 2013). Similarly, this challenge affects a large part of the population, given that only about 25% of Brazilians aged 25 or older have completed or are pursuing higher education, while the rest have at most a high school education (Bandeira, 2024).

Therefore, recognizing this issue, some courts have started adopting the use of plain language in legal documents. However, one of the key aspects to consider when drafting a text in plain language is the target audience. If the document is intended for a more technical audience, lexical simplification may not be necessary. On the other hand, if the document is to be used both internally and by different audiences, multiple simplified versions must be created, each tailored to its respective group. As a result, the cost of producing various simplified documents becomes high for institutions.

While efforts to simplify legal texts—through manual rewriting, visual law, or controlled language systems (Belém, 2013; Martínez et al., 2024)—have existed for decades, their scalability remains limited by human resource constraints. Generative AI introduces a paradigm shift: by automating simplification, it enables institutions to produce *multiple tailored versions* of the same document (e.g., for laypersons, students, or professionals) at negligible marginal cost. This scalability aligns with the constitutional mandate of accessibility (*Constituição*, n.d.) while addressing the socioeconomic disparity in education levels (Bandeira, 2024). However, the trade-off between automation and accuracy—particularly omissions and hallucinations (Ray, 2023)—demands rigorous evaluation, as undertaken in this study.

With the launch of ChatGPT in 2022 and the rapid public adoption of the tool, both the public and private sectors saw an opportunity to solve problems using these models. However, generative AIs can produce hallucinations, that is, incorrect information in the final response (Ray, 2023). Therefore, it is necessary for the generated content to go through a revision process. So far, the literature recommends that the public sector perform human reviews before making the content available to the general public (K. Alves et al., 2024) However, the review process is expensive in environments where a lot of content is generated by AI.

In this context, the goal of this work is to simplify and evaluate documents issued by the Court of Accounts of Pernambuco. For this, 2 generative AIs were used with 5 different prompt techniques: Tree of Thought, Zero Shot, One Shot, COSTA and Meta prompting; producing a sample set of simplifications. These simplifications were evaluated by 2 different AI models. Then, the simplifications from the model and prompt combination that received the highest average score were manually reviewed by a researcher to compare with the score given by the AIs. And assess the quality of the evaluations. Thus, both the simplifications and the evaluations were assessed.

The remainder of this paper is organized as follows. Section 2 provides the related works. Section 3 outlines the methodology used to develop the experiment. Section 4 details the results obtained. Section 5 discusses the results, followed by Section 6, presenting concluding remarks and recommendations for future work.

2. Background and related works

For a better contextualization of the study, four important topics will be detailed: Plain Language in Governments, Application of Generative AI in Governments, Prompt Techniques, and finally, a review of related works.

2.1 Plain language in Government

The main element of plain language is the reader, who must be able to use the text to achieve the intended purpose (Petelin, 2010).Therefore, it is necessary for the document to be tailored to the reader, rather than expecting the reader to adapt to the document. In this way, readers can access government information and promote greater transparency in the public sector (Petelin, 2010). Recognizing the benefits, many countries have begun adopting plain language in various public information like Australia (APSC (Australian Public Service Comission), 2023), Belgium (*Heerlijk Helder | Vlaanderen.Be*, n.d.), Canada (*Plain Language*, *Accessibility*, *and Inclusive Communications*

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

- *Privy Council Office - Canada.Ca*, n.d.) and Norway (*Klarspråk - Språkrådet*, n.d.).

Considering the U.S. scenario, in 1978, U.S. President Jimmy Carter issued an executive order to make federal regulations clearer [Document design: a, 1980], which led the Internal Revenue Service to spend considerable time reconstructing the tax form. The movement for the use of plain language also reached other government agencies, such as in Washington State Courts (Dyer et al., 2013), which reports the need for the court to use plain language, as approximately 65% of families who go to court in Washington do not have the assistance of a lawyer.

Furthermore, in Brazil, the Fiscal Responsibility Law (LRF), in Article 48, establishes that fiscal oversight agencies must widely disclose both original and simplified versions of the following documents: plans, budgets, and budgetary guidelines laws; financial statements and their respective prior opinions; and the summarized fiscal management report. However, Article 48 does not provide clear guidelines for the construction of simplified versions of these documents. Additionally, the Brazilian Court of Accounts Members Association (ATRICON) recommended, in mid-2023, the use of plain language and visual law in the creation of their documents (*Atricon Recomenda Que Tribunais de Contas Adotem Linguagem Simples e Direito Visual – Atricon*, n.d.).

2.2 Generative AI's applications

Generative Artificial Intelligence (GenAI), particularly large language models (LLMs), has undergone rapid evolution since its inception. The foundation for modern LLMs was laid by early neural language models like Word2Vec (Mikolov et al., 2013) and ELMo (Peters et al., 2018), which introduced contextual word embeddings. A significant leap occurred with the Transformer architecture (Vaswani et al., 2017), enabling models to process sequential data more efficiently through self-attention mechanisms. This breakthrough paved the way for models like GPT (Generative Pre-trained Transformer) (Openai et al., n.d.) and BERT (Devlin et al., 2019), which demonstrated the power of pre-training on large corpora followed by fine-tuning for specific tasks.

The release of ChatGPT in 2022 marked a turning point, showcasing the capabilities of LLMs in generating human-like text and engaging in conversational interactions. Built on the GPT-3.5 and later GPT-4 architectures (OpenAI, n.d.), ChatGPT achieved widespread adoption, reaching 1 million users in just five days. The tool began being used in a virous scenarios, ranging from assisting in literature reviews (Haman & Školník, 2024)to recipe recommendations with faster, more personalized, and diverse meal options (Papastratis et al., 2024). It was also investigated how ChatGPT can contribute to the software requirements engineering process, exploring how it can assist in the activities of elicitation, validation, and documentation of requirements (Marques et al., 2024).

In the public sector, these technologies are being cautiously adopted to bridge the gap between legal systems and citizens. Brazilian courts have pioneered applications ranging from document simplification (Silva et al., 2024) to AI-powered judicial assistants like JuLIA (Araújo, 2024). Brazil's national audit institution (TCU) has implemented AI tools to streamline internal processes, including document analysis and workflow automation (*Uso de Inteligência Artificial Aprimora Processos Internos No Tribunal de Contas Da União – Notícias | Portal TCU*, n.d.), demonstrating institutional commitment to technological innovation. The Brazilian Court of Accounts of Pernambuco' initiative examined in this study represents a critical advancement in this domain, demonstrating how AI can operationalize constitutional transparency mandates at scale. However, the use of these tools must be planned to reduce risks and have mitigation plans in place should these risks occur (K. Alves et al., 2024).

2.3 Prompt Technique

A prompt is the set of instructions sent as input to generative AI models. It is through these prompts that the models generate new data. However, generative AIs are not 100% accurate; they can hallucinate, meaning they may introduce incorrect data in the final responses. However, there are ways to improve the performance of the responses obtained. By constructing the prompt well, it is possible to minimize hallucinations and get responses that are closer to what is expected, without needing to retrain the language model. Thus, in this section, we clarify the prompt techniques used in the experiment conducted in this work. The following techniques were applied: Tree of Thought, Costar, Zero Shot Prompt, One-shot Prompt, and Meta Prompting.

- **Tree of thought**: In this prompt style, the problem is sent to the model without any input examples. However, the prompt explicitly asks the model to divide the problem into subproblems and generate alternative solutions for each of them. The model will then evaluate each possible solution and select the best one (Long, 2023).
- **Costar**: Costar is a framework to support the construction of prompts. In this model, the prompt must be constructed with the following aspects: context, objective, style, tone, audience, and response. In other words, all these aspects are mapped in the prompt to contextualize the LLM and also to determine the expected response format.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

- **Zero Shot Prompt**: In this prompt style, the task to be performed is described in detail, without labeled training data (Sahoo et al., 2024).Thus, the model is led to use its pre-existing knowledge through a deeply described activity.
- **One-shot Prompt**: The One-shot is the prompt style that refers to using an input example for model learning (Chen et al., 2024) In other words, the model will receive an input with its respective expected result, and the input will be used for the LLM to work and achieve an output based on the example input for learning.
- **Meta prompting**: This prompt technique focuses on the structure and format of the interaction with the LLM, allowing greater control over how the model processes and presents information (Zhang et al., 2024).Therefore, there is a greater concern in describing which topics should be addressed in the response, for example.

2.3 Related Works

Although generative AI has only recently become widely known, there are already several related works on text simplification using this technology. In Ospina-Henao et al. (Ospina-Henao et al., 2024), generative AI was used to assist in simplifying technical texts for people with cognitive impairments, the elderly, and non-natives. Martinez et al. (Martínez et al., 2024) highlight the existence of guides for creating simple and easy-to-read content in plain language. However, there is no standardization between these guides, and standardization usually needs to be done manually, which is more costly.

A prominent study in the area of automatic text simplification is presented at (A. Alves et al., 2023). A total of 100 documents from the Regional Federal Court of the 5th Region (TRF5) and 100 documents from the Supreme Federal Court (STF), two major Brazilian courts, were used. The simplifications were performed using MUSS(EN), MUSS(PT), Transformers, and NMT + Attention. After simplification, the texts were evaluated using the Flesch Reading Ease (FRE) method. Only the NMT + Attention technique did not improve text readability, while the Transformers model achieved a score of 64.71, the highest readability average compared to the original text in TRF5 documents. MUSS(EN) achieved a readability score of 60, making it the best-performing model for STF documents. The study also used a human evaluation form to assess the simplified texts; however, Plain Language guidelines were not applied to determine whether the texts were effectively simplified.

Another study is being presented by Silva et al. (Silva et al., 2024). In this work, the target audience for simplification was individuals with a high school education, and prior opinions issued by the Court of Accounts of Pernambuco were used. The ChatGPT-4 was used, and the prompt technique applied was the zero-shot prompt. The simplified texts in this work contained little or no technical language while maintaining the main points of the decision. However, the work used only one Large Language Model, one prompt technique, and no simplification process was performed using plain language guides.

3. Methodology

The main objective of this work is to transform government documents, often perceived as complex by the general public, into plain language. To achieve this, we formulated the following research questions:

RQ01 – Which prompt techniques and Large Language Models most effectively translate the State Court of Accounts of Pernambuco's preliminary decisions into plain language for the audience of at least high school graduates?

RQ02 – Which Large Language Model demonstrates superior performance in evaluating the quality of AI-generated plain language texts, as measured by consistency with human judgments?

To address these questions, we structured our methodology into six complementary steps, aiming to create simplified versions of the preliminary decisions that are both satisfactory and generated automatically. The six steps are: (i) collecting the preliminary decisions; (ii) creating ten simplified versions of the decisions; (iii) automatic evaluation of simplified documents; (iv) selecting the best model; (v) human evaluation; (vi) grade alignment analysis. Figure 1 illustrates the methodology steps.

3.1 Collecting the preliminary decisions

The preliminary decisions were obtained using a system called "Decisões Simplificadas" (Translates to "Simplified Decisions") (Silva et al., 2024) which already contained the decisions. This system performed preprocessing by dividing the original preliminary decisions into logical sections, which were then stored in a database for easy retrieval and use in generating simplified versions. The scope of the preliminary decisions was limited to a specific

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

state and its capital, as it is a state-level court of accounts. The analysis focused on the most significant decisions for the state and its capital, starting from year 2016, totaling 14 documents.

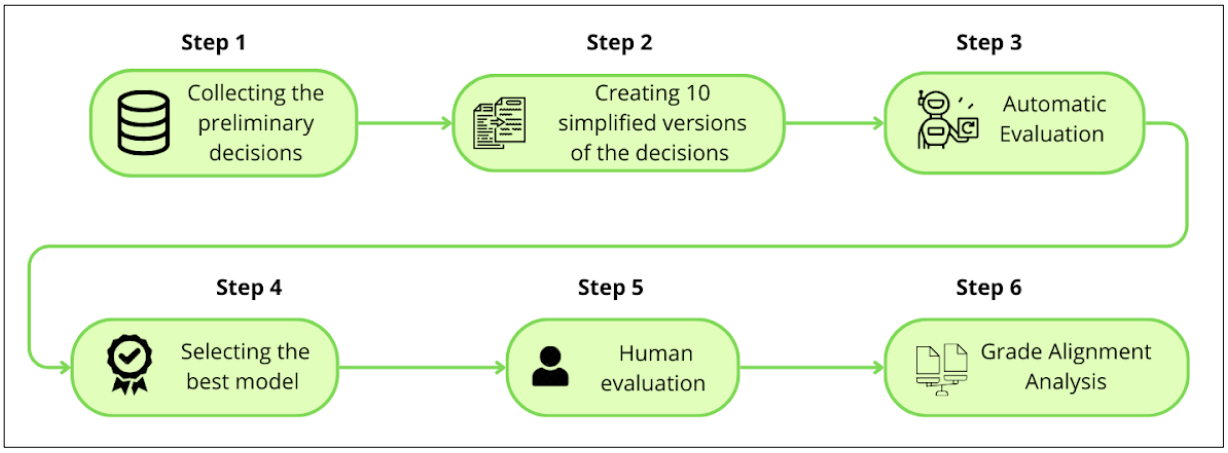

Fig. 1 – Methodology Diagram

3.2 Create ten simplified versions of the decision

Then, we chose five prompt techniques—zero-shot, one-shot, COSTAR, meta-prompting, and tree of thoughts—were selected for their varying approaches to contextual understanding and generative capabilities. The respective prompts are available in figures 2, 3, 4, 5 and 6. The prompts and all original texts were in Portuguese, the working language of the Court of Accounts.

```
Role:
You are a language expert specializing in plain and clear language.
Task:
Your task is to translate documents into plain language. To do this, you must follow the guidelines below, maintaining the most
important information and the structure of the text, while considering the target audience for whom the simplification is intended. You
should not summarize or condense texts; only translate them into plain language. Do not use markdown.
Target Audience:
General public, with a high school education, who want to know the results of municipal account judgments.
Guidelines:
Follow this algorithm:
1. Identify what needs to be said.
2. Identify what can be excluded.
3. Define the information architecture.
4. Structure the sentences.
5. Review the choice of words.
Use the order of importance in the content of the text:
• Essential content
• Important content
• Complementary content
• Accessory content
Information Architecture:
• Start the text with the most important point for the reader.
• Use lists or tables to organize information when necessary.
• Present only one idea per paragraph.
Sentence Construction:
• Be objective.
• Prefer active voice.
• Use sentences in direct order (subject + verb + complement).
• Avoid sentences interrupted by commas.
• Use affirmative sentences.
Word Choice:
• Explain technical terms and jargon.
• Use words common to the target audience.
• Avoid uncommon foreign words.
• Explain acronyms.

Fig. 2 – Zero Shot Prompt

Regarding the Large Language Models, Google's Gemini 1.5 flash and OpenAI's GPT 4o mini were selected. The decision to use these tools was based on their popularity and endorsement, which facilitate the process of simplification. To automate the process of generating each text, Python scripts were used to connect with the database containing the original preliminary decision texts. The GPT and Gemini APIs were then used to send the prompts, applying the chosen prompt technique along with the original text. The response from the API, containing the plain language version, was stored in a table within the same database.

```
Role:
You are a language expert specializing in plain and clear language.

Task:
Your task is to translate preliminary opinions into plain language. To do this, you must follow the guidelines below, maintaining the
most important information and the structure of the text, while considering the target audience for whom the simplification is
intended. You should not summarize or condense texts; only translate them into plain language. Maintain the general structure of the
text. Do not use markdown.

Target Audience:
General public, with a high school education, who want to know the results of municipal account judgments.

Guidelines:
Follow this algorithm:

1.      Identify what needs to be said.

2.      Identify what can be excluded.

3.      Define the information architecture.

4.      Structure the sentences.

5.      Review the choice of words.

Use the order of importance in the content of the text:

·        Essential content

·        Important content

·        Complementary content

·        Accessory content

Information Architecture:

·        Start the text with the most important point for the reader.

·        Use lists or tables to organize information when necessary.

·        Present only one idea per paragraph.

Sentence Construction:

·        Be objective.

·        Prefer active voice.

·        Use sentences in direct order (subject + verb + complement).

·        Avoid sentences interrupted by commas.

·        Use affirmative sentences.

Word Choice:

·        Explain technical terms and jargon.

·        Use words common to the target audience.

·        Avoid uncommon foreign words.

·        Explain acronyms.

Examples:
To illustrate the change in technical terms, see the following examples:
Original:
"The present Technical Opinion aims to analyze the request for Suspension of Bidding Process (doc. 1), requested by the company WT –
TECHNOLOGY, MANAGEMENT AND ENERGY S.A, a legal entity under private law, registered with the CNPJ/MF under no. 08.624.525/0001-00,
headquartered at Rua Carneiro Leão, no. 203, Brás, CEP. 03040-000, São Paulo/SP, duly represented by its partner Mr. THIAGO HENRIQUE
PESSOA, Brazilian, holder of Identity Card RG no. 25.927.596-7 and CPF/MF no. 220.858.618-22."

Simplified:
"This opinion analyzes the request for suspension of Bidding Process No. 004/2021 (doc. 1), requested by the company WT – Technology,
Management, and Energy S.A.
The bidding process is being conducted by the Public Intermunicipal Consortium of Agreste Pernambucano and Borders (CONIAPE), with the
following objective:
Price registration for engineering services related to the management of the public lighting system (doc. 7).

CONIAPE initiated the bidding process (doc. 7) in 2021. In November of the same year, the company WT was disqualified for not meeting
the technical qualification requirement specified in item 5.2 of the bidding notice.
On January 2, 2022, the company WT requested (doc. 1) the Court of Accounts to immediately suspend the bidding process. They claimed
that the Technical Archive Certificates (CAT) presented for their qualification exceeded the requirements of the notice.
The Municipal Works Audit Office/North (GAON) was asked to issue an opinion on the regularity of the notice and the documentation
presented by the company, as well as to assess the possibility of suspending the precautionary measure."

3.3 Automatic Evaluation:

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

In this step, the quality of the generated simplified versions was evaluated using two complementary approaches. First, an 18-question questionnaire, primarily based on Patricia Roedel's plain language guidebook (Roedel, 2024), was developed to assess adherence to plain language principles. This questionnaire included specific guidelines for simplification as well as broader questions about readability and comprehension. The original text, simplified text, and questionnaire were sent to the same large language models, which generated a score between 0 and 100 for each simplified version based on the plain language criteria. The questionnaire and the questions' weights is available at table 1.

```
Context:
You are a language expert specializing in plain and clear language. To ensure greater understanding by the general public, people with
a high school education, of the preliminary opinions of the Court of Accounts of the State of Pernambuco, the texts must be translated
into plain language.
Objective (O):
Your task is to translate voting documents into plain language so that the text of such documents is clear, easy to understand, but
maintains the meaning of the text. Initially, you should identify sentences and words that are difficult to read and then modify them,
following the style below:
Style (S):
Follow the guidelines below, maintaining the most important information and the structure of the text, while considering the target
audience for whom the simplification is intended. You should not summarize or condense texts; only translate them into plain language.
The text should follow this style:
1. Information Architecture:
- Start the text with the most important point for the reader.
- Use lists or tables to organize information when necessary.
- Present only one idea per paragraph.
2. Sentence Construction:
- Be objective.
- Prefer active voice.
- Use sentences in direct order (subject + verb + complement).
- Avoid sentences interrupted by commas.
- Use affirmative sentences.
3. Word Choice:
- Explain technical terms and jargon.
- Use words common to the target audience.
- Avoid uncommon foreign words.
- Explain acronyms.
Tone (T): The final text must retain all the information and the same structure as the original text but should be in plain language,
with the specified guidelines. Do not remove any information; keep everything and do not summarize.
Audience (A): The target audience for this text is the general public, who want access to a plain language version of a preliminary
opinion document, which indicates whether the accounts of a municipality, judged by the Court of Accounts of the State of Pernambuco,
were approved or not.
Response (R): The format must follow the plain language guidelines. Do not use markdown.
Text:
{&TEXTHERE&}
```

Fig. 4 – CoStar Prompt

In addition to the questionnaire-based evaluation, we assessed the readability of each simplified text using two standardized metrics: the Flesch Reading Ease (FRE) and Flesch-Kincaid Grade Level (FKGL).

The Flesch Reading Ease score, calculated using Portuguese-adapted formulas that account for the language's specific phonetic and syntactic characteristics, measures text accessibility on a scale from 0 to 100. Higher scores indicate greater readability, with scores above 50 generally considered appropriate for audiences with basic literacy skills. This metric considers both average sentence length and average syllables per word.

```
Task: Translate the following text with complex language into a simpler version, using the guidelines provided below.
Original Text: {&TEXTHERE&}
Translation Guidelines:
1. Information Architecture:
- Start the text with the most important point for the reader.
- Use lists or tables to organize information when necessary.
- Present only one idea per paragraph.
2. Sentence Construction:
- Be objective and direct.
- Prefer active voice and use sentences in direct order (subject + verb + complement).
- Avoid sentences interrupted by commas and prioritize affirmative sentences.
3. Word Choice:
- Explain technical terms and jargon.
- Use words common to the target audience.
- Avoid uncommon foreign words and explain acronyms.
Target Audience: The target audience for this simplification is the general public, with a high school education, who want to know the
results of municipal account judgments by the Court of Accounts of the State of Pernambuco.
Expected Response Structure: Return ONLY the text translated into plain language.
```

Fig. 5 – Meta Prompting

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

```
Scenario: Imagine three experts collaborating to translate a text of votes from the Court of Accounts of the State of Pernambuco into
plain and clear language, so it can be widely understood, following specific guidelines.
Guidelines:
Information Architecture:
- Start the text with the most important point for the reader.
- Use lists or tables to organize information when necessary.
- Present only one idea per paragraph.
Sentence Construction:
- Be objective.
- Prefer active voice.
- Use sentences in direct order (subject + verb + complement).
- Avoid sentences interrupted by commas.
- Use affirmative sentences.
Word Choice:
- Explain technical terms and jargon.
- Use words common to the target audience.
- Avoid uncommon foreign words.
- Explain acronyms.
Expert 1: Focuses on the structure of the text, ensuring it starts with the most important point and uses lists or tables when
necessary.
Expert 2: Focuses on sentence construction, ensuring sentences are objective, in direct order, and use active voice.
Expert 3: Focuses on word choice, replacing jargon with clear explanations, avoiding foreign words, and explaining acronyms.
Process: The process will follow these steps:
1. Each expert proposes an initial translation or refinement based on their area of focus.
2. Everyone evaluates the suggestions of the other experts and makes adjustments.
3. After several iterations, they arrive at a final version that is simple and clear.
Text to be translated: {&TEXTHERE&}
Additional Instructions: Start with the first iteration of the translation, following these guidelines. Each expert should write a
proposal in their area, and the group, with their expertise in plain language, will evaluate and refine the text before moving on to
the next step. The target audience for this simplification is the general public, with a high school education, who want to know the
results and process of municipal account judgments.
Required Final Format: This is not a summary or simplification but a full translation of the text into plain language. Send only the
final text, which must contain all the information from the original text. No markdown.
```

Fig. 6 – Tree of Thought

The Flesch-Kincaid Grade Level metric converts the FRE score into the corresponding U.S. educational grade level needed to comprehend the text. Lower scores represent simpler texts that require less formal education to understand. For our target audience of high school graduates (typically corresponding to grade 12), we aimed for FKGL scores at or below this threshold. These Portuguese-adapted versions of the tests maintain the original metrics' validity while accounting for linguistic features specific to Portuguese, such as its typically longer words and more complex verb conjugations compared to English.

The combination of these two approaches—questionnaire scores and readability metrics—allowed for a comprehensive evaluation of the simplified texts. The questionnaire scores were used to determine how well the simplified versions adhered to plain language principles, while the readability metrics provided objective measures of text complexity. Together, these evaluations helped identify the best-performing model.

3.4 Selecting the best model:

Scores were calculated using a weighted average, with each question assigned a specific weight, based on the importance of each question. Particular emphasis was placed on assessing whether the large language model omitted information or generated hallucinations, ensuring the output was a true simplification rather than a summary (questions q1 and q2). Besides, higher weights were also given on questions 17 and 18, Using the LLM-generated scores for each simplified version, the next step was to determine the best-performing model by identifying the combination of prompt technique and Large Language Model that achieved the highest average grade. Alongside this, the Flesch Reading Ease and Flesch-Kincaid Grade Level metrics were calculated to verify whether the simplified versions were indeed easier to read compared to the original texts. While these readability metrics were not used to select the best model, they provided additional validation that the simplified texts were more accessible to a broader audience.

3.5 Human evaluation:

The original version of the document, the simplified version, and the questionnaire were sent to human evaluators, who assessed the 14 text samples from the prompt-model combinations that achieved the best average performance. Although the human evaluators were not language specialists, they received instructions on how to conduct the evaluations, including guidelines on the principles of plain language, its objectives, and its definition. These evaluations were limited to the simplified versions produced by the selected best-performing model. To quantify the differences between human and LLM grades, tests on Mean Absolute Error (MAE) and Mean Absolute Percentage Error (MAPE), metrics widely used in the evaluation of AI models were conducted. These metrics were chosen as they provide clear insights into the consistency and accuracy of the LLM evaluations compared to human assessments.

Tab. 1 – Evaluation Questionnaire

No.	question	weight
q1	Does the simplified text omit any information from the original text?	5
q2	Does the simplified text include any information that is not in the original text?	5
q3	Does the text present the most important information first?	1
q4	Does the text structure the information using lists, tables, graphs, etc.?	1
q5	Does the text convey only one idea per paragraph?	1
q6	Does the text use the minimum number of words?	1
q7	Does the text use the active voice?	1
q8	Does the text use direct word order?	1
q9	Does the text avoid sentences with intercalated clauses separated by commas?	1
q10	Does the text use words that are generally familiar to the target audience?	1
q11	Does the text translate technical terms and jargon?	1
q12	Does the text use precise words?	1
q13	Does the text spell out acronyms in full?	1
q14	Does the text avoid foreign words without common usage?	1
q15	Does the text avoid nominalizing verbs?	1
q16	Does the text use any pejorative terms?	1
q17	Has the simplification compromised the full understanding of the content?	3
q18	Is the simplified text appropriate for the target audience's level of knowledge?	3

4. Results

In the following section, we present the results achieved, discussing the most relevant aspects of the implemented methodology and the findings obtained during its development.

4.1 Research Question 01

For Research Question 01, "Which prompt techniques and Large Language Models most effectively translate the State Court of Accounts of Pernambuco's preliminary decisions into plain language for the audience of at least high school graduates?", it was crucial to identify the best-performing prompt technique and large language model for translating text into a plain language version. To develop this, it was necessary to understand the overall performance of each combination of prompt techniques and large language model. Each preliminary decision was sent to GPT 4o mini and Gemini 1.5 flash, using five different prompts for evaluation. The evaluation process then generated automatic scores, as described in the methodology section.

With the automatic scoring system, we evaluated different combinations of prompt techniques and large language models (LLMs) to determine the most effective approaches, as summarized in Table 2. The results show that Gemini achieved the highest score (67.64) using the "Tree of Thought" technique, followed closely by its performance with "COSTAR" (67.36). GPT's strongest results came from the same "Tree of Thought" approach (67.21), slightly outperforming its "COSTAR" score (66.07). Notably, Gemini consistently scored higher than GPT across most techniques, with the exception of "Tree of Thought," where GPT was nearly on par. The weakest performance came from GPT using "Meta Prompting" (62.79), which scored lower than even GPT's "Zero Shot" baseline (63.71). Overall, structured techniques like "Tree of Thought" and "COSTAR" delivered the best results for both models, suggesting that methodical, multi-step prompting strategies yield superior performance compared to simpler approaches like zero-shot or one-shot prompting.

Table 3 illustrates the omission rate, additional info rate, comprehension compromised rate, and audience suitability rate from each combination of prompt technique and LLM. These rates were based on the questionnaire responses to Questions 1, 2, 17, and 18, where the values are expressed as percentages. As shown, GPT with the

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

COSTAR and Zero Shot (90%) technique had the lowest omission rate, even though this means that from all of the documents, 90% had something missing. This was closely followed by Gemini with the Tree of Thought technique, which also performed well. Most models struggled to follow the instructions to avoid omitting information, with most exhibiting an omission rate of 100%, indicating either missing information or significant data loss. On a positive note, none of the models added information that was not present in the original text, indicating they did not hallucinate.

Tab. 2 – Average Score of each model

Average Score	LLM	Prompt Technique
67,64	gemini	Tree Of Thought
67,36	gemini	COSTAR
67,21	gpt	Tree Of Thought
66,71	gemini	One Shot
66,07	gemini	Meta Prompting
66,07	gpt	COSTAR
65,71	gemini	Zero Shot
63,71	gpt	Zero Shot
62,79	gpt	Meta Prompting
60,71	gpt	One Shot

Regarding the comprehension compromised rate, GPT led with the Tree of Thought at 37%, followed by Gemini with One Shot at 45%, and Gemini with Tree of Thought at 50%, maintaining a good average across the rates. For audience suitability, all models performed well, except for Gemini using the COSTAR prompt.

Tab. 3 – Omission, additional info, comprehension compromised and audience suitability rate by model

LLM	Prompt Technique	Omission Rate	Additional Info Rate	Comprehension Compromised Rate	Audience Suitability Rate
gemini	Tree Of Thought	91%	0%	50%	100%
gpt	Tree Of Thought	100%	0%	37%	100%
gemini	Meta Prompting	100%	0%	54%	100%
gpt	Meta Prompting	100%	0%	59%	100%
gpt	COSTAR	90%	0%	63%	100%
gemini	Zero shot	100%	0%	50%	100%
gpt	Zero shot	90%	0%	59%	100%
gemini	One Shot	100%	0%	45%	100%
gpt	One Shot	100%	0%	59%	100%
gemini	COSTAR	100%	0%	50%	90%

Table 4 presents readability scores for different prompt techniques and the two different models utilized, compared with the original texts. The readability metrics were the Flesch Reading Ease (FRE), which has higher scores for easier to read texts, and Flesch-Kincaid Grade Level (FKGL), that has lower scores for easier to read texts. The original text has very low readability (FRE: 11.13) and a high FKGL score (22.71), indicating that it is highly complex and likely inaccessible to a general audience, which confirmed the need for simplification to enhance accessibility. GPT + COSTAR achieved the best readability score (FRE: 55.26, FKGL: 8.82), which was approximately five times the original FRE metric, going from 'very difficult' score to just below the plain language standard,

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

making it the most effective at simplifying the text. Tree of Thought, by the metrics, underperformed compared to other techniques, especially with Gemini, which was contrary to the other conclusions.

Tab. 4 – Flesch and Flesch-Kincaid for each model

Prompt technique	LLM	FRE average	FKGL Average
Original text		11.13	22.71
COSTAR	gpt	55.26	8.82
Meta Prompting	gpt	54.97	8.40
Zero shot	gpt	53.62	8.75
One Shot	gpt	51.86	9.22
Tree Of Thought	gpt	50.79	9.39
COSTAR	gemini	44.66	11.43
One Shot	gemini	40.51	11.11
Meta Prompting	gemini	40.40	11.43
Tree Of Thought	gemini	39.40	13.10
Zero shot	gemini	36.29	12.68

Overall, based on all metrics from the tables 2, 3, and 4 the best-performing combination for simplified text generation was Gemini with Tree of Thought, which had the highest average score, created the best simplified version for four of the preliminary decisions, kept a good average across the rates, even though it had a non-satisfactory result in the readability metrics. This model was followed by GPT with COSTAR, which created the best scored simplified version, lowest omission rate, and the second highest average score.

4.2 Research Question 02

To address Research Question 02—"Which Large Language Model demonstrates superior performance in evaluating the quality of AI-generated plain language texts, as measured by consistency with human judgments?"—we conducted a comparative analysis between AI-generated evaluations and human assessments. This evaluation aimed to determine the reliability of large language models in assessing the quality of simplified preliminary decisions.

As described in the methodology section, the evaluation process involved human raters grading the simplified versions produced by the best-performing prompt technique and LLM combination (Gemini with Tree of Thought). The human evaluations were then compared with the AI-generated scores from both Gemini and GPT to quantify discrepancies. To measure the degree of deviation between human and AI-generated scores, we employed Mean Absolute Error (MAE) and Mean Absolute Percentage Error (MAPE).

Tab. 5 – MAE and MAPE for each model

LLM	MAE	MAPE
Gemini	22.14	32.34%
GPT	16.79	25.76%
Average	19.03	28.5%

The results indicate that GPT provided scores that were closer to human evaluations than Gemini. GPT's lower MAE and MAPE suggest a more reliable alignment with human judgment, making it a stronger candidate for evaluating plain language texts. In contrast, Gemini's higher MAE and MAPE suggest a greater deviation from human ratings, meaning its evaluation system might not be as precise for this specific task.

A notable finding is that the AI-generated scores consistently overestimated readability and clarity, suggesting that

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

large language models may havea bias toward assuming their outputs are clearer than they actually are for human readers. Additionally, while Gemini outperformed GPT in text simplification, it performed worse in evaluation, raising concerns about its effectiveness as an assessment tool.

Another important observation is the variability of AI evaluations across different texts. While some simplified versions received similar scores from both AI and human evaluators, others showed significant discrepancies. This suggests that AI evaluations may struggle with certain linguistic features, such as legal terminology, sentence complexity, or implicit contextual meaning.

5. Discussion

This study demonstrates that Large Language Models can *operationalize* plain language principles at scale, a task previously hindered by labor-intensive manual processes (Petelin, 2010). Where traditional simplification relies on linguists or legal experts to draft single versions, AI models like Gemini and GPT generate context-aware variants in seconds, as evidenced by our 140 simplified texts. This efficiency could transform public institutions' capacity to comply with transparency laws (e.g., Brazil's LAI) while reducing costs. However, our findings reveal a critical gap: AI's tendency to omit details (Table 3) mirrors the 'summary effect' observed in early machine translation (A. Alves et al., 2023), underscoring that *scalability does not equate to reliability*. Hybrid workflows—combining AI's speed with human oversight for legal precision—emerge as the optimal path forward.

Haman & Školník (2024) demonstrated GPT's potential for complex texts, which we extend to legal simplification. Alves et al. (2023) improved readability using models like Transformers and MUSS, but our study goes further by incorporating plain language principles, human evaluation, and a hybrid approach to ensure both readability and information retention. These comparisons highlight our study's novelty in enhancing public access to legal information while addressing prior limitations.

As for ethical and legal considerations, the deployment of AI for legal text simplification raises critical challenges regarding accountability (e.g., determining liability for errors in AI-generated documents), risks of misinformation from model hallucinations or omissions, and potential erosion of public trust in official records. These concerns are particularly acute in legal contexts where precision is paramount, as highlighted by AI safety literature (Ray, 2023) and emerging regulations like the EU AI Act's high-risk classification for public-sector AI. While Brazil's evolving AI governance framework acknowledges transparency needs (K. Alves et al., 2024), specific safeguards for legal applications—such as mandatory human review of AI outputs, audit trails, and public education about AI-processed documents—must be prioritized to balance accessibility with legal integrity.

However, despite promising results, some challenges can be highlighted. GPT outperformed Gemini in accuracy, suggesting its reliability for preliminary assessments. However, discrepancies between human and AI scores indicate that a hybrid approach—combining AI with human review—is most effective. Despite structured prompts, omissions were common, showing that critical information loss remains a risk. Another limitation noted is the small sample size, which may be sufficient for a preliminary analysis, however may not capture the full complexity of legal languages across diverse contexts.

Moreover, human evaluation was limited to 14 simplified versions due to resource constraints and conducted by non-specialists, potentially introducing bias. While evaluators were trained in plain language principles, their lack of legal expertise could affect judgments about information retention and clarity. Incorporating feedback from both legal professionals and target audience representatives (e.g., high school graduates) would strengthen future evaluations. Additionally, the cost of proprietary models like Gemini and GPT is a limitation, and future studies could explore open-source models for cost-effective solutions. Lastly, models evolve and new models are being created constantly, as in the case of the very recent DeepSeek (DeepSeek-AI et al., 2025), launched on the week of the submission of this paper. Thus, methodologies like the one presented in this study, mostly based on the prompt rather than exactly on the basis model, are important to be pursued.

While this study focused on proprietary models (GPT-4 and Gemini), open-source alternatives like Mistral and LLaMA offer potential cost-effective solutions, though their performance on legal text simplification remains untested. Domain-specific improvements could be achieved through fine-tuning on Brazilian legal corpora or Retrieval-Augmented Generation (RAG) architectures to reduce omissions of critical legal concepts. The superior evaluation accuracy of GPT over Gemini (Table 5) may stem from architectural differences—GPT's reinforcement learning from human feedback (RLHF) appears better optimized for consistency with human judgments, whereas Gemini's strength in creative generation may compromise evaluation precision. Future work should investigate whether these performance gaps persist when models are specifically adapted to legal Portuguese and constrained by RAG systems.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Finally, the study focused on Portuguese-to-plain-Portuguese simplification, which poses unique challenges due to grammatical structures (e.g., complex verb conjugations) and untranslatable legal terms. While readability metrics were adapted for Portuguese, further research is needed to address cultural and linguistic nuances that AI models may overlook. These limitations highlight the need for hybrid human-AI workflows to ensure both accessibility and precision.

Future research should investigate AI consistency over time, incorporate qualitative methods like expert interviews, and develop hybrid evaluation frameworks combining AI and human judgment. Exploring domain-specific AI models, prompt engineering, and ethical implications, such as biases in multilingual contexts, could further refine AI's role in text evaluation. This study lays the groundwork for developing robust, fair, and adaptable AI-assisted evaluation frameworks.

6. Concluding Remarks

Enhancing the clarity of public documents to improve citizen comprehension is a global goa., moreover in the context of Brazil's redemocratization and the need for greater transparency in public administration, the 1988 Constitution established the right to access public information. However, the complexity of legal language, particularly in court documents, poses a significant barrier to understanding for the general public. This study aimed to address this issue by leveraging large language models to simplify legal texts from the Court of Accounts of Pernambuco into plain language, making them more accessible to individuals with a high school education level. The research sought to identify the most effective combination of prompt techniques and AI models for this task, while also evaluating the reliability of AI-based assessments of simplified texts.

The methodology involved generating 140 simplified versions of 14 preliminary decisions using two large language models (GPT and Gemini) and five prompt techniques (Tree of Thought, COSTAR, Zero Shot, One Shot, and Meta Prompting). These simplifications were evaluated using an 18-question questionnaire based on plain language principles, with scores generated by AI models and validated through human review. The study also analyzed readability metrics, omission rates, and audience suitability to assess the quality of the simplified texts.

For RQ01, which focused on identifying the most effective prompt techniques and AI models for simplifying legal texts, the results showed that Gemini with the Tree of Thought technique achieved the highest average score (67.64) based on responses to the plain language questionnaire, and produced the best simplified versions for four of the 14 decisions. However, GPT with the COSTAR technique also performed well, particularly in preserving essential information and achieving the highest readability scores (Flesch Reading Ease: 55.26), which was just below the plain language standard. Despite these successes, omissions of critical information were a common issue across all models, indicating the need for human oversight to ensure the integrity of the simplified texts.

For RQ02, which examined the effectiveness of AI models in evaluating plain language texts, the findings revealed that GPT outperformed Gemini in evaluation accuracy, with lower Mean Absolute Error (MAE) and Mean Absolute Percentage Error (MAPE) compared to human evaluations. However, AI models tended to overestimate readability and comprehension, suggesting that while they can provide rapid preliminary assessments, human review remains essential for ensuring the quality and accuracy of simplified texts.

The study also highlighted the practical implications of using Large Language Models for text simplification in the public sector. By automating parts of the simplification process, governments can reduce costs and improve accessibility to legal and administrative documents. However, the findings emphasize the importance of a hybrid approach, combining AI-generated simplifications with human review to address limitations such as omissions and readability overestimations. This approach can enhance transparency and citizen participation in public administration, aligning with the goals of the Access to Information Law (LAI) and the Open Government Partnership (OGP).

The main contributions of this work include: (i) identifying the most effective prompt techniques and AI models for simplifying legal texts, (ii) demonstrating the potential and limitations of AI-based evaluations for plain language transformations, and (iii) proposing a hybrid evaluation framework that integrates AI-generated assessments with human oversight. These findings provide a foundation for future research on AI-assisted text simplification and evaluation in the public sector.

For future work, we recommend: (i) exploring domain-specific fine-tuning of open-source AI models to improve performance and reduce costs, (ii) conducting longitudinal studies to assess the consistency of AI evaluations over time, (iii) incorporating qualitative research methods to gain deeper insights into the strengths and limitations of AI-driven evaluations, and (iv) investigating the ethical and cultural implications of AI-based text simplification to ensure inclusivity and fairness. By addressing these areas, future research can develop more robust and reliable

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

tools for plain language transformation, ultimately enhancing public access to legal and administrative information.

Submitted: 31 January 2025, Revised: 26 March 2025, Accepted: 21 April 2025, Published: 23 May 2025

Abstract. This study explores the factors influencing civil servants' perceptions of generative AI-assisted work performance, focusing on extrinsic and intrinsic motivations and the moderating role of organizational power, as measured by government level and organizational rank. Artificial Intelligence (AI) has emerged as one of the most influential technologies, driving transformation in both government and society. Generative AI, as a subfield of AI, has gained recognition for its capabilities to automate routine tasks, enhance decision-making, and improve work productivity. However, little is known about who perceives the positive effects of these tools on performance and why. Drawing on the notion that motivations affect work performance and the reinforcement politics model, this study analyzes survey data from 1,608 Korean civil servants collected by the Korean Institute of Public Administration (KIPA) in April 2023, when generative AI was still in its early stages of development. The survey targeted civil servants from central, provincial, and local governments to gauge their perspectives on generative AI-assisted work performance. This study employed partial least squares structural equation modeling (PLS-SEM), an appropriate method for predictive modeling and identifying key driving factors in complex relationships to investigate the connection between two types of motivation and perceived work performance. The findings reveal that extrinsic and intrinsic motivations positively influence perceived work performance, with intrinsic motivation having a more substantial effect. Also, extrinsic motivation significantly enhances intrinsic motivation, highlighting the dynamic interaction between the two constructs. However, the moderating effects of government level and organizational rank on the relationship between motivations and perceived work performance were not statistically significant. These results underscore the critical role of individual motivation in shaping perceptions of generative AI tools while suggesting that organizational power may play a less significant role in this context than previously anticipated. Theoretically, this study provides empirical evidence supporting the idea that motivations affect work performance by demonstrating the effectiveness of generative AI tools in public administration while challenging the reinforcement politics model. It challenges the foundational assumption of the model that organizational power makes a significant impact on the adoption and effectiveness of generative AI tools.

1. Introduction

Artificial Intelligence (AI) refers to "a cluster of technologies that enables machines to learn and autonomously solve cognitive problems without human intervention" (Madan & Ashok, 2022). AI has emerged as one of the most significant technologies, facilitating digital transformation in government and society. We expect it to significantly

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

transform the work environment, driving efficiency and innovation across various sectors (Boyd & Wilson, 2017). Generative AI, a subfield of AI, is "a computational technique capable of producing new and meaningful content, such as text, images, audio, video, and even computer code, from training data" (Feuerriegel et al., 2023). This technology serves as a transformative force that can potentially drive significant change. It replicates complex data distributions to generate outputs that closely resemble or surpass the quality of real-world data (Banh & Strobel, 2023; Lehmann & Buschek, 2020; Tomczak, 2024). Generative AI tools have been widely and rapidly diffused. Since its release in November 2022, ChatGPT has reached over 200 million weekly active users by August 2024, doubling its user base from the previous year. Its subscription-based service, ChatGPT Plus, serves approximately 10 million users (Backlinko, 2024).

Advocates claim that generative AI tools facilitate task performance by efficiently handling routine or resource-intensive activities (e.g., drafting and reviewing documents, analyzing data to identify patterns, and automating repetitive tasks like filing, scheduling, or data entry) (Brynjolfsson et al., 2023). These advantages allow individuals to focus on more highly valued activities—a benefit particularly significant for civil servants, who spend up to 30% of their time on paperwork and administrative duties (Gmyrek et al., 2023; Viechnicki & Eggers, 2017). Conversely, critics raise concerns about ethical and legal challenges, including the risk of producing inaccurate, biased, or irrelevant outputs, which could hinder their reliability and task performance (Bloch-Wehba, 2021; Bender et al., 2021). Despite these controversies and its early stages of development, some public administration scholars and government professionals have paid significant attention to its impact on the government (Wirtz et al., 2018; Salah et al., 2023). However, little is known about who perceives the positive effects of these tools on work performance and why, particularly in the context of the public sector.

Empirical studies on generative AI tools in public administration have been limited in recent years. Most research (Noonpakdee, 2024) primarily focuses on adoption as the technology remains in its early stages of development (Al Naqbi et al., 2024; Bright et al., 2024). These studies provide valuable insights into the government's adoption of technology. However, there is a limited understanding of how individuals, particularly government employees, perceive the benefits of their work performance and the factors that influence these perceptions. To address this gap, this study examines how civil servants' organizational power and extrinsic and intrinsic motivations influence their perceptions of generative AI-assisted work performance. It is important to note that adopting generative AI tools—without exploring their effectiveness—may not ensure meaningful implementation in the public sector. We draw on extrinsic and intrinsic motivations and the reinforcement politics model, as these frameworks provide complementary perspectives on how individual and organizational factors shape perceptions of work performance. By employing the partial least squares structural equation modeling (PLS-SEM), we analyze survey data from civil servants collected by the Korea Institute of Public Administration (KIPA) in April 2023, when generative AI tools were still in their early development stages. This survey targeted civil servants from the central, provincial, and local governments to evaluate their perspectives on generative AI-assisted work performance. By analyzing these relationships, this study provides theoretical insights into the adoption of generative AI and its impact on public administration and practical implications for effective implementation. These findings will assist policymakers and government officials in understanding the conditions under which generative AI tools enhance work performance.

The paper is organized as follows: Section 2 presents a literature review that examines generative AI tools and their impact on public administration. Section 3 outlines the theoretical framework, drawing on the two types of motivations and the reinforcement politics model to establish the foundation for the study's conceptual model and hypotheses. Section 4 represents the theoretical model and nine hypotheses. Section 5 describes the data collected by KIPA and details the dependent, independent, moderator, and control variables. Section 6 draws the results of the PLS-SEM, underscoring the significant effects of two types of motivations on perceived work performance and the non-significant moderating role of organizational power. Section 7 interprets the findings based on the results and discusses their theoretical and practical implications. Section 8 summarizes the core findings and recommends effectively implementing generative AI tools into public administration.

2. LITERATURE REVIEW

2.1 Generative AI Tools

AI encompasses a range of technologies that enable machines to learn and autonomously solve cognitive problems without human intervention (Madan & Ashok, 2022). It drives innovation across various sectors by using machine and deep learning to analyze data, identify patterns, and enhance decision-making independently (Brynjolfsson & Mitchell, 2017; Brynjolfsson et al., 2023). The McKinsey Global Institute predicts that AI will significantly improve productivity, leading to transformative shifts in workplace efficiency (Gaurav et al., 2018). Generative AI, a subfield of AI, refers to computational methods that can create new and meaningful content—like text, images, or audio—by learning patterns from existing training data (Feuerriegel et al., 2023). This technology acts as a transformative force that can drive significant change. The technology replicates complex data distributions to produce outputs that closely resemble or surpass real-world data quality (Lehmann & Buschek, 2020; Tomczak, 2024). By modeling high-dimensional probability distributions, it creates seemingly new samples that reflect the underlying structure

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

of the original data (Ruthotto & Haber, 2021; Tomczak, 2024; Weisz et al., 2023). Unlike traditional AI systems that map input features to output labels, generative AI focuses on understanding data structures to generate new and meaningful content (Jebara, 2004).

Generative AI stands out because of its unique characteristics, setting it apart from many historical technological advancements, like the internet, which have primarily been driven by government-led initiatives (Goldman Sachs Global Institute, 2023). Conversely, its development and growth are dominated by a few tech companies, including OpenAI, Alphabet (Google), and Microsoft, which control digital platforms (Birch & Bronson, 2022). Traditional AI has become ubiquitous in powering advertising algorithms, content recommendations, and social media targeting, typically functioning behind the scenes on platforms like Apple's Siri, yet generative AI has brought its capabilities to the forefront, making its influence more visible and directly impactful. In their intermediary roles, Generative AI tools also resemble social media platforms, such as Facebook and X, connecting users with service providers within a platform economy driven by network effects (Wörsdörfer, 2022). As users and service providers increase, these platforms become increasingly attractive, fostering monopolistic dynamics and consolidating technological power structures (Jullien & Sand-Zantman, 2021; Sharon & Gellert, 2024). By February 2024, 23% of adults in the United States reportedly used OpenAI's ChatGPT, up from 18% in July 2023 (Backlinko, 2024). This indicates the rapid adoption and increasing reliance on generative AI tools, even in the workplace. The reliance has resulted in markets dominated by a handful of firms that wield unparalleled power and resources. These firms further centralize their authority and operate beyond the reach of traditional government-led governance. The changes in power dynamics raise critical questions about accountability (Khanal et al., 2024).

Moreover, many businesses are increasingly implementing generative AI tools in their workplaces, leveraging their ability to enhance productivity by combining human beings with machine computational power. The tools facilitate task automation, streamline workflows, and support decision-making (Nakavachara et al., 2024; Rana et al., 2024). Empirical studies (Budhwar et al., 2023; Goldstein, 2023; Fauzi et al., 2023; Kumar, 2024; Peng et al., 2023) have shown the significant impact of generative AI tools on work performance. For instance, Brynjolfsson et al. (2023) found that generative AI tools enhanced employee productivity by 14%, while Noy and Zhang (2023) reported a 40% decrease in task completion time for writing-intensive work. Similarly, Dell'Acqua et al. (2023) demonstrated that consultants from the Boston Consulting Group, a profession known for demanding workload, completed tasks 25% faster with generative AI tools, showcasing their efficiency in high-intensity environments. Even job seekers have benefited from AI-driven automation in resume writing and portfolio creation, which has increased efficiency and reduced costs (Malhotra et al., 2021). Despite certain drawbacks (De Cremer et al., 2023; Morshidi et al., 2023), most literature has underscored generative AI's performance benefits across sectors. However, there is a limited understanding of who perceives the positive effects of these tools on their work performance and why, particularly in the context of the public sector. To address the gap, this study explores how civil servants' organizational power, and their two types of motivations influence their perceptions of generative AI-assisted work performance.

2.2 Generative AI Tools in Public Administration

AI has advanced unprecedentedly, transforming various industries, reshaping daily life for citizens, and redefining interactions with emerging technologies like generative AI. These tools analyze patterns in existing datasets and generate seemingly new and meaningful content (Dasborough, 2023; Hadi et al., 2023). This rapid evolution drives significant changes in working environments, where generative AI enhances performance by automating routine tasks and facilitating idea generation (Androniceanu, 2024; Castro & New, 2016; Hoffmann et al., 2024; Wirtz et al., 2018). While the private sector has effectively leveraged these tools to streamline operations, reduce staffing needs, and lower costs (Rana et al., 2024), the government faces distinct challenges as it prioritizes the public interest and ensures equitable access to services over efficiency-driven outcomes (Council of the European Union, 2023).

Accountability and equity, foundational principles of public administration, present opportunities and challenges in adopting and implementing generative AI (Erkkilä, 2020). These tools enhance decision-making by efficiently processing large datasets, identifying patterns humans may overlook, and automating routine tasks such as filing, scheduling, or data entry. This enables civil servants to relieve themselves of simple administrative burdens, such as drafting and reviewing documents, and focus more on highly valued activities and strategic priorities, fostering greater accountability and responsiveness to citizens' needs (Salah et al., 2023). However, their "black box" nature and lack of transparency in reasoning raise significant accountability concerns, as even software developers do not fully comprehend how these algorithms function (Bloch-Wehba, 2021; Radford et al., 2019). Equity challenges also emerge due to biases embedded in the training datasets of generative AI tools, often derived from culturally narrow, predominantly English internet sources. Such biases hinder fairness and exacerbate systemic disparities, affecting marginalized groups disproportionately (Bender et al., 2021; Faisal et al., 2021; Schramowski et al., 2023).

Despite challenges such as algorithmic bias, data privacy risks, and environmental concerns related to high energy consumption, generative AI has gained widespread adoption in the public sector, especially among civil servants, due to its ability to enhance efficiency and foster innovation (Bright et al., 2024). Civil servants, who allocate up to 30% of their time to paperwork and administrative duties, can utilize automation to focus more on higher-value

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

activities and strategic priorities (Gmyrek et al., 2023; Viechnicki & Eggers, 2017). Like its transformative effect on other industries, generative AI has the potential to reshape public-sector operations, fundamentally redefining the roles and responsibilities of civil servants (Criado et al., 2020). The Boston Consulting Group (2024) also indicates that this technology could result in annual productivity improvements estimated at $1.75 trillion globally across all levels of government by 2033. Moreover, generative AI assists in policy development, decision-making, public service delivery, and citizen engagement, significantly transforming public administration and redefining the roles of civil servants (Salah et al., 2023). As governments encounter increasing pressure to transition to a digital society, the potential of generative AI is becoming clear in its ability to boost administrative efficiency, promote equitable and impactful public services, and provide vital support to less experienced and entry-level workers (Bright et al., 2024; Brynjolfsson et al., 2023).

Empirical studies on generative AI tools in public administration have been limited in recent years. Most research (Noonpakdee, 2024) focuses on adoption as the technology remains in its early development stages (Al Naqbi et al., 2024; Bright et al., 2024). These studies provide valuable insights into the government's adoption of technology. However, there is a limited understanding of how individuals perceive the benefits of their work performance and the factors that shape these perceptions. To address the gap, this study examines how civil servants' organizational power, and two types of motivations influence their perceptions of generative AI-assisted work performance. It is important to note that simply adopting generative AI tools—without exploring its effectiveness—may not ensure meaningful implementation in the public sector. Therefore, we draw on the extrinsic and intrinsic motivations and the reinforcement politics model as these frameworks provide complementary perspectives on how individual and organizational factors shape perceptions of work performance.

3. THEORETICAL FRAMEWORK

3.1 Motivation in Work Performance

Motivation in the workplace is crucial for clarifying differences in an employee's work performance. Motivation is an internal force that energizes, directs, and sustains behavior over time (Diefendorff & Chandler, 2011). Intrinsic motivation stems from a genuine interest in or enjoyment of an activity. It is linked to high-quality performance and improved employee well-being, even when applied to specific tasks (Ryan & Deci, 2000). Hawthorne studies (Mayo, 1949; Landsberger, 1968) suggested that work conditions can influence productivity, drawing attention to organizational psychological and social dynamics. These findings facilitated the development of core theories like Maslow's Hierarchy of Needs (1943), suggesting that employees are motivated to fulfill a sequence of needs, and Herzberg's Two-Factor Theory (1959), which differentiated between hygiene factors that prevent dissatisfaction and motivators that promote satisfaction. While these theories have faced methodological critiques (Hackman & Oldham, 1976), they laid the groundwork for understanding how external and internal motivations interact in the workplace. While motivation theories often emphasize intrinsic factors, extrinsic rewards are still important—particularly for attracting and retaining talent. Extrinsic motivation, influenced by external reward or pressure, is often effective in achieving short-term goals and meeting organizational expectations. A reward system combining material and psychological incentives has been shown to enhance employee satisfaction and performance, aligning each value and task goal (Gagné & Deci, 2005).

Maslow's Hierarchy of needs suggests that once fundamental needs are satisfied, psychological needs become more powerful motivators in the workplace than basic physiological ones. Employees pursue fulfillment by striving for higher-level needs like esteem and self-actualization. Similarly, Herzberg (1959) suggested that although monetary compensation can initially motivate employees, its effectiveness diminishes over time, redirecting the motivational focus toward psychological and social factors. In this context, McGregor (2002) reinforced this perspective through Theory Y, which emphasizes intrinsic motivations in contrast to the extrinsic motivations highlighted in Theory X. Nevertheless, extrinsic motivation remains a fundamental motivational tool for motivating employees, particularly in attracting and retaining talent, and it is embedded in many performance-based incentive systems (Taylor, 1919; Bishop, 1987). Some scholars often study two types of motivations to understand their impact on employee work performance (Moran et al., 2012).

Recent empirical studies (Baard et al., 2004; Rhoades & Eisenberger, 2002; Moran et al., 2012; Van den Broeck et al., 2016) have emphasized the key role of motivation in improving workplace performance. Motivation is generally divided into extrinsic and intrinsic types, with each playing a unique role in employee engagement and productivity (Deci et al., 2001). Intrinsic motivators, such as knowledge, accomplishment, and stimulation, significantly enhance employee engagement and task performance (Weinberg & Gould, 2023; Amabile et al., 1994). Similarly, Chintalloo and Mahadeo (2013) and Khan et al. (2014) observed that two types of motivations drive higher work performance, while Abdullatif (2016) mentioned that extrinsic factors provide a foundation for motivation and intrinsic factors, intrinsic motivation positively influencing employee performance. Although motivation has been widely studied concerning workplace performance across sectors, limited research has investigated who perceives the benefits of adopting emerging technologies, why, and what factors shape this perception—especially within the public sector. To address this gap, this study explores how civil servants' organizational power and motivational factors influence

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

their perceptions of generative AI-assisted work performance. Furthermore, given the structural characteristics of public organizations—often more bureaucratic and centralized than their private-sector counterparts and focused on public interest (Perry & Rainey, 1988)—this study provides valuable insights into how two types of motivations influence employee performance in the context of advanced technology adoption.

3.2 Reinforcement Politics Model

Reinforcement politics model (Kraemer & Dedrick, 1997; Kraemer & King, 1986; Kraemer & King, 2006) provides a framework for understanding how the impact of computing technologies—such as mainframe computers in the 1980s and early 1990s and later e-government technologies—was significantly shaped by individuals in positions of power within government organization. Organizational power, defined as the authority to make decisions within a hierarchical structure (Pinsonneault & Kraemer, 1993), enables these individuals to influence the adoption and implementation of technologies in ways that reinforce existing power dynamics (Pinsonneault & Kraemer, 1997). Technologies play a key role in shaping how control over information is exercised, with information becoming a critical resource of power in decision-making. While information is not inherently powerful, those with access to and control of it can influence decisions and maintain authority in bureaucratic structures (Kraemer & King, 1986). Emerging technologies have the potential to either centralize or decentralize access to information, yet their actual use often reflects and reinforces pre-existing hierarchies. Furthermore, the allocation of critical resources, such as budgets and technical infrastructure, is typically managed by senior civil servants, further consolidating the power.

According to the reinforcement politics model, civil servants with organizational power are more likely to perceive greater benefits from supporting the adoption of generative AI tools. However, during the early stages of adopting and diffusing emerging technologies within government organizations, these individuals might face uncertainties surrounding implementation. Such uncertainties challenge the assumption that technological innovations serve the interests of those in power or reinforce existing hierarchies (Lee, 2008). Emerging technologies can disrupt established workflows, raise concerns about operational reliability, and complicate the process of decision-making. Bureaucrats used to traditional systems may resist adoption due to concerns about transparency, effectiveness, or the potential erosion of their authority. This resistance is often driven by a desire to maintain institutional stability, particularly when technological governance frameworks are designed to protect the interests of those already in power. In contrast, individuals with less organizational power may regard emerging technologies as opportunities to challenge the status quo. By acquiring specialized expertise and leveraging emerging tools to influence decision-making processes, individuals can reposition themselves as valuable contributors, potentially shifting the balance of authority and redefining organizational roles.

In recent years, several empirical studies (Burkhardt & Brass, 1990; Heintze & Bretschneider, 2000; Jasperson et al., 2002) have examined the political dynamics surrounding technology adoption, emphasizing that the success of emerging technologies depends not only on their technical features but also on organizational power structures and individuals' adaptability to change. Kraemer and King (1986) suggested that computing technologies will likely reinforce existing organizational arrangements: individuals favoring centralization use information technologies to strengthen control, while those advocating for decentralization employ them to promote autonomy. Similarly, Chelmis and Prasanna (2013) suggested that managers are more effective than peer pressure in encouraging the adoption of emerging microblogging platforms among their employees. However, Lee (2008) observed that lower-ranking civil servants in Korea were among the early adopters of electronic approval systems (EAS), suggesting that resistance to technological innovation—particularly in its early developmental stages—often originates from entrenched power hierarchies and concerns over potential threats to established roles. Lee's study also noted that high-ranking officials in the central government adopted such technologies more readily than their counterparts in local government. While much of the existing literature argues that adopting information technology influences organizational dynamics, relatively little research has investigated who perceives these tools as beneficial to their work performance and why, especially within the public sector. Heintze and Bretschneider (2000) are among the few scholars who suggest that the adoption of information technology may have a limited impact on organizational dynamics but can directly improve performance. To address this gap, this study examines how the organizational power of civil servants, alongside their extrinsic and intrinsic motivations, shapes their perceptions of generative AI-assisted work performance.

4. THEORETICAL MODEL & HYPOTHESIS

In Figure 1, the conceptual model demonstrates the relationships between two types of motivations and perceived work performance, with organizational power, as indicated by government level and organizational rank—acting as moderating factors. H1 assumes a relationship between extrinsic motivation and perceived work performance, whereas H3 posits that extrinsic motivation influences intrinsic motivation. Both extrinsic and intrinsic motivation were hypothesized to independently affect perceived performance (H1 and H2, respectively). The moderating role of organizational power was examined at the government level (H5a and H6a) and organizational rank (H5b and H6b), which may either strengthen or weaken these motivational effects. Additionally, H4a and H4b investigated the direct effects of government level and organizational rank on perceived work performance. Collectively, this

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

model provides a comprehensive framework for understanding how two types of motivations and organizational power dynamics influence perceived work performance.

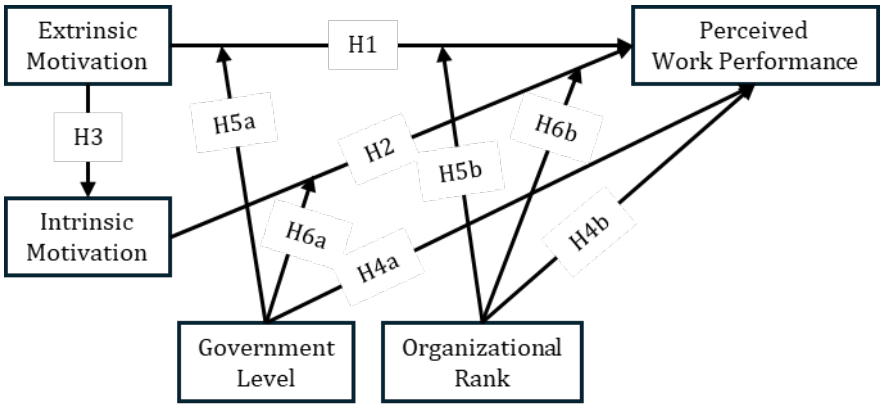

Fig. 1 – Research Model

H1: Civil servants with stronger extrinsic motivation are more likely to perceive improved work performance when utilizing generative AI tools than those with weaker extrinsic motivation

H2: Civil servants with stronger intrinsic motivation are more likely to perceive improved work performance when utilizing generative AI tools than those with weaker intrinsic motivation

H3: Civil servants' extrinsic motivation positively influences their intrinsic motivation when utilizing generative AI tools

H4a: Civil servants at higher levels of government are more likely to perceive improved work performance when utilizing generative AI tools than those at lower levels

H4b: Civil servants in higher organizational ranks are more likely to perceive improved work performance when utilizing generative AI tools than those in lower organizational ranks

H5a: Government level moderates the relationship between extrinsic motivation and perceived work performance when utilizing generative AI tools, such that the positive relationship is stronger for civil servants at higher levels of government

H5b: Organizational rank moderates the relationship between extrinsic motivation and perceived work performance when utilizing generative AI tools, such that the positive relationship is stronger for civil servants in higher organizational ranks

H6a: Government level moderates the relationship between intrinsic motivation and perceived work performance when utilizing generative AI tools, such that the positive relationship is stronger for civil servants at higher levels of government

H6b: Organizational rank moderates the relationship between intrinsic motivation and perceived work performance when utilizing generative AI tools, such that the positive relationship is stronger for civil servants in higher organizational ranks

5. METHODOLOGY

5.1 Data

This study utilized survey data collected by KIPA in April 2023 to test nine hypotheses. The survey targeted Korean civil servants from central, provincial, and local governments to explore their perceptions of generative AI-assisted work performance. The questionnaire consisted of five sections: (1) general perceptions of generative AI, (2) user experiences in work-related contexts, (3) perspectives of non-users, (4) views on adopting generative AI tools in government affairs, and (5) demographic information. The survey was not explicitly designed for the study; only a subset of relevant items was analyzed. Each questionnaire was translated from Korean to English using ChatGPT.

A total of 1,608 responses were collected using a Computer-Assisted Web Interviewing (CAWI) system between April 21 and April 27, 2023, when generative AI was still in its early stages of development. The participants were

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

recruited by various channels, including an official cooperation letter from the Ministry of the Interior and Safety (MOIS), banners, and online panels, ensuring voluntary participation. The survey was conducted by Next Research and commissioned by KIPA. Among the respondents, 545 were from the central government, 416 from provincial governments, and 647 from local governments. The respondents included civil servants from a wide range of roles, ranging from rank three (senior officials) to rank nine (entry-level positions) within the Korean civil service system, with lower rank numbers indicating higher positions. At the time of the survey, generative AI tools were optional, with decisions left to individual discretion. Table 1 represents the demographic characteristics of the participants, such as gender, age, government level, and organizational rank.

Tab. 1 – Demographic Characteristics of the Participants

Demographics	*Category*	*Subjects (N = 1,608)*	
		Frequency	*Percentage*
Gender	Male	801	49.8
	Female	807	50.2
Age	20s	211	13.1
	30s	601	37.4
	40s	500	31.1
	50s	287	17.8
	60s and above	9	0.6
Government Level	Central	545	33.9
	Provincial	416	25.9
	Local	647	40.2
Organizational Rank	Rank 3 or above	6	0.4
	Rank 4	33	2.1
	Rank 5	165	10.3
	Rank 6	359	22.3
	Rank 7	487	30.3
	Rank 8	304	18.9
	Rank 9	254	15.8

5.2 Measurement

Dependent Variable

The study's dependent variable is perceived work performance, a latent construct evaluated utilizing the PLS-SEM method. Perceived work performance reflects employees' subjective evaluations of productivity, effectiveness, and quality of contribution (Deci & Ryan, 1985; Ryan & Deci, 2000). Initially, an item inquired where respondents had utilized generative AI tools in their work; however, it was excluded because of low Cronbach's alpha and composite reliability. Instead, it was measured using an item that evaluated how participants perceived the effectiveness of generative AI tools across five dimensions: reducing workload, improving work efficiency, generating new ideas, enhancing the quality of work outputs, and increasing client or stakeholder satisfaction. The item used a five-point Likert scale: 1 = strongly disagree, 2 = disagree, 3 = neutral, 4 = agree, and 5 = strongly agree. This approach offered a more robust measurement of participants' perceptions of work performance.

Independent Variable

The independent variables consist of two types of motivations: extrinsic and intrinsic. Extrinsic motivation, driven by external rewards or pressures, effectively achieves short-term goals and meets organizational expectations. In contrast, intrinsic motivation, derived from internal satisfaction and genuine interest in tasks, promotes creativity, problem-solving, and long-term commitment (Gagné & Deci, 2005). Extrinsic motivation was measured across two dimensions: superior directives and expectations of improved performance evaluations. However, the former was excluded due to low Cronbach's alpha and composite reliability. Therefore, extrinsic motivation was only assessed using the expectations of improved performance evaluations. Intrinsic motivation was also measured across two dimensions: capturing enjoyment and interest in using generative AI tools at work. As with the dependent variable, participants' responses were recorded on a five-point Likert scale. This refined approach ensured a more reliable

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

assessment of the independent variables.

Moderator

The moderators represent the government levels and organizational ranks. Organizational power, or the authority to make decisions within a hierarchy, is commonly measured through the levels of government and organizational rank (Pinsonneault & Kraemer, 1993). Initially, organizational power was conceptualized as a single moderator; it was divided into two constructs after Cronbach's alpha and composite reliability fell below acceptable thresholds, indicating insufficient reliability. Government level was coded as central government (1), provincial government (2), and local government (3), demonstrating a hierarchy from higher to lower governance levels. Organizational rank reflects the civil system hierarchy in Korea, with ranks ranging from nine (1) to three or above (7), indicating a progression from lower to higher ranks. This study ensured the reliability and validity of organizational power as a moderating variable by treating government level and organizational rank as distinct constructs.

Control Variable

The control variables are gender and age. Gender was determined based on participants' responses. The item was pre-coded in the dataset as male (1) or female (2). Age was reported by respondents and categorized into groups on an ordinal scale: 20s (2), 30s (3), 40s (4), 50s (5), and 60s and above (6), indicating a progression from younger to older. This coding improved clarity and consistency in analyzing demographic controls.

5.3 Estimation Model

This study utilized the PLS-SEM model using Smart PLS 4.0 software (Ringle et al., 2015). This model is especially effective for predictive models and identifying key driving factors in complex relationships (Hair et al., 2011). This study utilized a sample of civil servants from central, provincial, and local governments to examine perceptions of generative AI-assisted work performance. These perceptions are influenced by extrinsic and intrinsic motivations, with organizational power measured by government level and organizational rank as moderating factors. In Korea, emerging technologies have historically been promoted and implemented mainly by the central government, while provincial and local governments tend to adopt these technologies at later stages (Lee, 2008). This gap highlights the potential role of organizational power in influencing civil servants' motivation to utilize generative AI tools. To analyze these dynamics, PLS was used to evaluate the relationships between motivation types and perceived work performance while considering the moderating effects of organizational power.

6. RESULTS

6.1 Measurement Model

Cronbach's alpha and composite reliability (CR) were calculated to assess reliability, and both values exceeded the recommended threshold of 0.7, as suggested by Hair et al. (2019) (Table 2). Factor loadings were well above 0.708, and the Average Variance Extracted (AVE) exceeded 0.5, indicating strong convergent validity (Bagozzi et al., 1991; Hair & Alamer, 2022). Discriminant validity was evaluated using two established criteria. First, the square root of the AVE for each construct was greater than its correlations with other constructs, satisfying Fornell and Larcker's (1981) criteria (Table 3). Additionally, the Heterotrait-Monotrait (HTMT) ratio of correlations was analyzed, with all constructs falling below the recommended threshold of 0.85 (Henseler et al., 2015) (Table 4). The results tested the measurement model's reliability and validity.

Tab. 2 – Reliability and Validity

Construct	*Item*	*Mean*	*Standard deviation*	*Factor loading*	*Cronbach's alpha*	*CR (rho_a)*	*CR (rho_c)*	*AVE*

6.2 Structural Model

A bootstrap resampling method with 1,608 resamples was employed to evaluate the structural models. The results indicate that extrinsic motivation significantly positively affects perceived work performance ($\beta = .155$, $p < .05$), supporting H1. In addition, extrinsic motivation positively affects intrinsic motivation ($\beta = .179$, $p < .05$), supporting H3. Intrinsic motivation significantly influences perceived work performance ($\beta = .414$, $p < .05$), supporting H2. In contrast, government level ($\beta = .034$, $p > .05$) and organizational rank ($\beta = -.013$, $p > .05$) do not significantly affect perceived work performance, indicating that H4a and H4b are not supported. Furthermore, the moderating effects of government level and organizational rank on the relationship between extrinsic motivation and perceived work performance are not statistically significant (H5a: $\beta = -.032$, $p > .05$; H5b: $\beta = .002$, $p > .05$). Also, their moderating effects on the relationship between intrinsic motivation and perceived work performance are not significant (H6a: $\beta = .008$, $p > .05$; H6b: $\beta = -.036$, $p > .05$). Lastly, the model accounted for 23% of the variance in perceived workplace performance. Figure 2 presents a structural model summarizing the PLS-SEM results.

7. DISCUSSION

7.1 Theoretical Implications

This study provides empirical evidence supporting the idea that motivation affects work performance by showing the effectiveness of generative AI tools in public administration but challenging the reinforcement politics model regarding organizational power dynamics in technology adoption. This underscores the essential role of intrinsic motivation among civil servants in enhancing their perceived work performance when utilizing generative AI tools. Civil servants who enjoy these tools are likelier to perceive enhanced productivity and efficiency. Additionally, the positive relationship between the two types of motivation suggests that external incentives, such as recognition or improved evaluations, can enhance intrinsic motivation under certain conditions. However, this study challenges the basic assumption of the reinforcement politics model that organizational power dynamics significantly impact the adoption and effectiveness of new technologies. Contrary to expectations, organizational power did not directly impact perceived work performance or strengthen the relationship between two types of motivation and perceived work performance. This discrepancy may arise from how generative AI tools and computing technologies were developed. Information technologies have primarily been driven by government-led initiatives, which have made them compatible with government affairs (Goldman Sachs Global Institute, 2023). In contrast, generative AI has been primarily developed and advanced by a few major tech companies (Birch & Bronson, 2022). Furthermore, since the data was collected when the generative AI tool was still in its early development stages, its compatibility with government functions may not have been fully recognized.

7.2 Practical Implications

This study underscores the practical implications for the government as it aims to adopt and implement generative AI tools in the workplace. To enhance civil servants' intrinsic motivation, the government is introducing training programs demonstrating how these tools can streamline workflows, improve decision-making, and facilitate work productivity. Drawing on Singapore and Iceland, fostering an environment that encourages curiosity, innovation, and active participation is essential for maximizing the benefits and value of these technologies. The public sector faces high employee turnover, with many civil servants shifting to the private sector for more competitive salaries (Ciobanu & Androniceanu, 2015). The Korean civil service system has historically been rigid and based on seniority. Despite recent efforts to incorporate performance-based approaches, it still lags the private sector (Kim, 2005; Kim, 2014). Given this structure, automating administrative tasks with generative AI tools can help civil servants focus more on high-value activities and strategic priorities (Viechnicki & Eggers, 2017). Kim and Chung (2021) suggests that information technologies such as big data and cloud computing have had little impact on improving efficiency at the organizational level within Korean government institutions. However, this study emphasizes the need for a supportive infrastructure that facilitates the adoption of generative AI tools, as motivation—particularly extrinsic incentives—plays a crucial role in shaping individual perceptions of work performance. To leverage these tools in addressing public sector challenges, the government implements thoughtfully designed incentives encouraging adoption among civil servants. Moreover, aligning these incentives with external rewards, professional aspirations, and public service value is vital for ensuring long-term adoption and meaningful impact.

7.3 Limitations and Future Research

This study had several limitations. It relied solely on cross-sectional data collected through the CAWI system, which may introduce self-selection bias due to open participation via a publicly accessible government agency website. While utilizing a government platform helps mitigate this risk—since it is less accessible than commercial search engines like Google and Bing—there remains the possibility that individuals who are not government employees may misrepresent themselves as civil servants. Moreover, the data were collected in April 2023, when generative

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

AI was still in its early development stages. Consequently, the findings may not align with the current technological landscape or accurately reflect the evolving capabilities of generative AI. Methodologically, this study encountered limitations in its measurement model, as some latent variables were represented by fewer than the recommended three indicators, potentially affecting the robustness and reliability of the measurements. However, since the data were collected by KIPA rather than specifically for this study, it relied on a limited number of indicators for certain constructs due to data constraints. To address the issues, we employ PLS-SEM, which is well-suited for models with fewer indicators and complex relationships. By maximizing explained variance and enabling flexible modeling of latent constructs, PLS-SEM helped mitigate measurement limitations and enhance the validity of the results (Hair et al., 2017). Lastly, this study only focused on the Korean public sector, which may restrict the applicability of its findings to other contexts.

Future research should adopt a longitudinal approach to track changes over time to address the above limitations, providing a comprehensive understanding of how perceptions of generative AI-assisted work performance evolve. Expanding the scope beyond Korea by conducting comparative studies in various cultural and institutional settings could further enhance the applicability of the findings. Such studies would provide deeper insights into potential motivations and variations in organizational power dynamics, enabling a better understanding of how generative AI influences public sector performance across different governance structures and policy environments. Finally, additional indicators for each latent variable in future models would enhance the measurement's precision and reliability, leading to more robust and generalizable conclusions.

8. CONCLUSION

This study examines the factors influencing civil servants' perceptions of generative AI-assisted work performance, focusing on two types of motivations and the moderating effects of organizational power. The findings reveal that both types of motivation positively influence perceived work performance, with intrinsic motivation having a more significant impact. Furthermore, extrinsic motivation significantly enhances intrinsic motivation, underscoring the dynamic interplay between these two motivational constructs. However, contrary to expectations, organizational power—assessed by government levels and organizational ranks—did not significantly moderate the relationship between motivations and work performance. This indicates that traditional power structures have less influence on government adoption and its effects than earlier technological advancements.

Theoretically, this study empirically supports the idea that motivation affects work performance by demonstrating the effectiveness of generative AI tools in public administration while challenging the reinforcement politics model regarding organizational power dynamics in technology adoption. Intrinsic motivation plays a crucial role in civil servants' perceived work performance when utilizing generative AI tools, and external incentives can significantly enhance intrinsic motivation. However, organizational power did not directly impact perceived work performance. Practically, the government should boost motivation through training programs that promote curiosity, creativity, and problem-solving, fostering an innovation-friendly environment while using automation to enable greater focus on high-value activities and strategic priorities. Additionally, aligning external incentives with public service values and professional aspirations is essential for ensuring long-term adoption and maximizing the impact of generative AI in the public sector.

Despite its contributions, this study has several limitations. It relies on cross-sectional data collected via the CAWI system, which may introduce self-selection bias since a government website facilitated participation. While using a government platform mitigates their risk, non-civil servants still can misrepresent their identities. Additionally, data were collected in April 2023, when generative AI was still in its early development stages, meaning that the findings may not reflect its current capabilities. Methodologically, some latent variables were measured with fewer than the recommended three indicators due to data constraints; however, PLS-SEM was used to address this issue and enhance model validity. The study focuses on the Korean public sector, which limits its generalizability to other contexts. Future research should utilize a longitudinal approach to monitor the evolving perceptions of AI-assisted work performance, broaden its scope to encompass various cultural and institutional settings, and integrate more indicators to enhance measurement precision and model reliability.

Submitted: 31 January 2025, Revised: 26 March 2025, Accepted: 21 April 2025, Published: 20 May 2025

Abstract. Legislative documents present substantial obstacles to summarization due to their complex argument structures and specialized terminology. This research investigates the application of Large Language Models (LLMs) in summarizing Brazilian legislative proposals from the Chamber of Deputies, examining a dataset of over 56 thousand texts from 2013 to 2023. The paper explores three main summarization methodologies: extractive, abstractive, and hybrid, with an emphasis on abstractive summarization using LLMs. The performance of the LLM LLAMA2-13b is assessed using metrics such as ROUGE, BLEU, METEOR, BERTScore, and BERTopic, compared against reference summaries. The results show that LLMs can generate coherent and informative summaries, with positive evaluation metric results. Notably, the study reveals that traditional summary evaluation metrics may not be adequate for evaluating LLMs in summarization tasks. On the other hand, metrics based on pre-trained models like BERT provide a more effective evaluation of this innovative automatic summarization approach.

Keywords. large language models, summarization, legislative proposals.
Research paper, DOI: https://doi.org/10.59490/dgo.2025.969

1. Introduction

In the domain of Natural Language Processing (NLP), text summarization is the process of automatically generating a concise summary that retains the most relevant information from a longer text document, preserving the core or key ideas from the original document (Neto et al., 2002). The academic literature in the NLP field identifies three main types of text summarization methods: (i) extractive, (ii) abstractive, and (iii) hybrid summarization. Extractive summarization selects the most relevant sentences, phrases, or passages from the original text to build the summary without modifying the extracted content. Abstractive summarization employs state-of-the-art natural language processing techniques to interpret the text at a semantic level and generate new content and sentences for the summary. These generated summaries may be fully rephrased or completely rewritten, rather than directly extracting text spans. Hybrid summarization combines techniques that merge extractive and abstractive summarization, typically extracting key text spans from the original text and then rewriting or enhancing them for conciseness and readability (Abualigah et al., 2020; Egan et al., 2022; El-Kassas et al., 2021; Ermakova et al., 2019; Liu et al., 2022; Tas & Kiyani, 2007).

This study investigates the application of Large Language Models (LLMs) for abstractive summarization of legislative proposals from Brazil's Chamber of Deputies over the period from 2013 to 2023. The study uti-

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

lizes a corpus (Souza, Vitório, et al., 2021) containing over 56 thousand legislative proposal texts, complete with textual data, metadata, and pre-generated reference summaries. Within the scope of LLMs, the LLAMA2 (refer to Section 4) model was chosen to produce an automated summary for each legislative proposal text in the dataset. The proposed work addresses the task of summarizing legal documents, a recurrent task in the domain of Legal Natural Language Processing (Jain et al., 2021). This task aims to automatically generate concise overviews that capture the key information from lengthy and complex legal texts, such as contracts, case law, regulatory documents, and government legislative documents. Legal summarization, as a specific field of knowledge, poses unique challenges compared to other domains due to the specialized terminology, complex argument structure, and the need to preserve the legal validity of summaries.

2. Related Works

2.1. Summarization in Legal Domain

In this section, we describe studies that are important for understanding the importance of summarization in legal documents. Jain et al. provide a comprehensive state-of-the-art review that categorizes summarization techniques along two dimensions: domain-specificity (independent vs. specific) and approach type (extractive vs. abstractive). Their analysis predominantly covers extractive methods while offering limited discussion of abstractive summarization, despite the latter's greater complexity and potential for legal applications (Jain et al., 2021). Lucke et al. employed a technology-neutral methodology and multi-criteria analysis to identify several potential AI applications within parliamentary legislative processes. Their research prioritized these applications by relevance and significance, highlighting four key areas: intelligent scrutiny of legislative proposals, machine-readable legislation conversion, smart law implementation, and AI-enhanced parliamentary transparency (von Lucke et al., 2022).

Galgani et al. present a hybrid approach for legal text summarization focused on catchphrase creation for case reports. Their evaluation compares extraction methods (rule-based, citation-based, and general-purpose) using Rouge scores. The rule-based system achieved higher precision, while combining it with the citation-based method improved recall without sacrificing precision (Galgani et al., 2012). In the deep learning domain, Anand & Wagh implemented a semi-supervised approach for legal document extractive summarization using neural networks. They generated labeled data from reference summaries and evaluated quality through a set of metrics against human-generated headnotes. Their model demonstrated superior performance, validating sentence transformation effectiveness for labeled data creation (Anand & Wagh, 2022).

In the field of natural language processing for Portuguese legal documents, we refer to specific initiatives in analyzing legislative documents for the Chamber of Deputies of Brazil (Albuquerque et al., 2022; Souza, Moriyama, et al., 2021; Souza, Vitório, et al., 2021; Vitório et al., 2022, 2023).

2.2. Summarization with LLMs

In related literature, we highlight conversational Large Language Models (LLMs) — models specifically fine-tuned for dialogue-based interactions — as an emerging approach for automated text summarization. The application of these conversational LLMs to legal text summarization remains an evolving field. We believe that the studies discussed below offer valuable methodological insights for future research in this domain. Throughout our experimental process, we confirmed that the approaches examined in this section demonstrate applicability to legal text summarization scenarios.

Luo et al. (Luo et al., 2023) examined ChatGPT's capability to evaluate factual inconsistencies in text summarization using zero-shot learning, a technique where a language model performs a task without any prior examples or task-specific training, relying solely on its pre-trained knowledge and the instructions provided in the prompt. Their study employed various prompts for entailment inference, summary ranking, and consistency rating tasks, comparing ChatGPT's performance against established evaluation metrics across multiple datasets. While their results demonstrated ChatGPT's potential, they identified limitations in handling abstractive summaries and prompt alignment, suggesting future research directions in prompt engineering and alignment optimization.

In related work, Wang et al. (Wang et al., 2023) investigated ChatGPT as an evaluation metric for Natural Language Generation (NLG). Their experiments spanned five NLG meta-evaluation datasets, comparing ChatGPT

with existing automatic metrics. Their findings revealed ChatGPT's strong correlation with human judgments, its sensitivity to prompt formulation, and the significant influence of meta-evaluation dataset creation methods on NLG metric effectiveness.

In the field of Generative Pre-trained Transformers (GPT) (Brown et al., 2020), Goyal et al. (Goyal et al., 2022) examined the effectiveness of prompt-based models for text summarization, using GPT-3 as their primary case study. Their research compared GPT-3 against both fine-tuned models and a multi-task instruction-tuned model, employing parallel human and automatic evaluations across diverse summarization tasks. Their findings revealed that human annotators consistently preferred GPT-3-generated summaries, which demonstrated notable flexibility in handling tasks with varying constraints. However, they identified a significant evaluation gap: current automatic metrics failed to accurately capture the quality and diversity of GPT-3 summaries, frequently assigning them lower scores despite their superior human ratings.

3. Legislative Proposal Text Dataset

This section presents a quantitative and qualitative analysis of the corpus of legislative documents of the Brazilian Chamber of Deputies (Souza, Vitório, et al., 2021). The corpus comprises several types of legislative proposals, mainly: Bill or Law Project (*"Projeto de Lei" - PL*), Complementary Bill or Law Project (*"Projeto de Lei Complementar" - PLC*), and Constitutional Amendment Proposal (*"Proposta de Emenda Constitucional" - PEC*), totaling 56,391 documents. Each document in the corpus has attributes used in this experiment: proposal identification (author's name, proposal date), original text of the proposal, and manually generated reference summaries. For the experiment conducted, the summary present in the dataset is considered the reference summary, which will be compared with the summary generated by the LLM. Other attributes were not considered in the experiment. In the experiment, the reference summaries were obtained through a process of manual summarization, carried out by the creators of the original dataset. For examples of the structure of a legislative proposal document, we refer to the document site of the Brazilian Chamber of Deputies[1].

Table 1 presents a numerical description of the corpus, detailed by year, that shows the volume of proposals generated during the period analyzed. The textual data, spanning from 2013 to 2023, show the overall variation in the number of documents per year, starting from 5,394 proposals in 2013, peaking at 6,724 in 2021, then decreasing to 4,657 in 2022, and further to 2,389 in 2023. The average text length of analyzed documents also saw significant changes, increasing from 606 words in 2013 to 782 words in 2019, followed by an increase to 1,057 words in 2023.

Throughout the analyzed period, the average length of the reference summaries remained stable, ranging from 31 to 35 words. In the dataset, all reference summaries were written manually. In contrast, the average length of summaries generated by the LLM model varied, starting at 96 words in 2013 and reaching 127 words in 2023. This discrepancy in summary lengths is attributed to the fact that creating reference summaries is more labor-intensive and time-consuming, as they depend on the availability of individuals to perform manual summarization, while the automated generation of summaries using LLMs requires mainly computational resources. This shows the model's capability to understand the text semantically in greater depth and provide longer and more elaborate summaries.

4. Experiments

4.1. Documents Preprocessing

For the preprocessing stage of the proposal texts and summaries, it was necessary to develop a pipeline for text cleaning to make them suitable for summarization tasks. In summary, the steps adopted in the study were: (i) analyzing the text to remove punctuation, line breaks, and unnecessary spacing; (ii) removing meaningless words and special characters; and (iii) sentence segmentation and tokenizing words from reference summaries for use with evaluation metrics.

Tab. 1 – Annual statistics of Brazilian legislative proposals (2013-2023). The table presents yearly document counts, average proposal length (in words), and summary length comparison between human-generated reference summaries and LLM-generated summaries. Note the consistent discrepancy between reference and LLM summary lengths across all years.

Documents			Avg. Summary Length (words)	
Year	**Document Count**	**Avg. Length**	**Reference**	**LLM**
2023	2,389	1,057.0	35.0	127.0
2022	4,657	928.5	35.1	110.5
2021	6,724	899.7	33.3	109.5
2020	6,666	986.2	34.7	117.6
2019	8,257	782.6	31.2	106.3
2018	3,116	835.2	33.3	103.6
2017	5,336	738.6	31.2	102.8
2016	4,090	804.8	30.8	103.5
2015	7,156	768.4	31.7	105.3
2014	2,606	773.1	31.7	103.2
2013	5,394	606.2	31.3	96.9

4.2. LLM and Prompt Engineering

The LLAMA2-13b model[2], a cutting-edge language model by Meta, was selected for the experiments (Touvron et al., 2023). As a member of the LLAMA2 family, it is one of several generative text models pre-trained and fine-tuned with parameters ranging from 7 billion to 70 billion.

The LLAMA2-13b model was chosen due to its optimal balance of cost and performance, as these models are known for their computational intensity and expense. This auto-regressive language model utilizes an optimized transformer architecture and has been fine-tuned through supervised fine-tuning and reinforcement learning with human feedback (RLHF) (Christiano et al., 2017), ensuring alignment with human preferences for helpfulness and safety. For the experiments, the LLAMA2-13b model was deployed in its dialogue-optimized format on the Huggingface platform [3].

Figure 1 illustrates the text summarization process using the LLAMA2-13b model. The summarization flow begins with two initial inputs: the original "Document" to be summarized and a "Reference Summary" that serves as a quality benchmark for the generated summary. The "Text Preprocessing" stage represents an intermediate step where the original document undergoes processing to eliminate unnecessary information, normalize the text, and prepare it for the summarization model. At the "Large Language Model" stage, a zero-shot prompt is provided to summarize the text. The "Input" and "Output" components indicate the language model's processing flow: the "Preprocessed Text" resulting from the text preprocessing step serves as input, while the "Summary" represents the final summarized text output.

For generating summaries with the LLAMA2-13b model, we employed specific parameters empirically determined through iterative experimentation until summary generation achieved reasonable adequacy: (i) $temperature = 0.01$, the lowest possible value to prevent model hallucination (Rawte et al., 2023); (ii) $truncate = 4,096$, to avoid processing texts with character counts exceeding this established threshold; and (iii) $max_new_tokens = 500$ as the maximum number of tokens to be generated in the summary.

5. Main Results

This section presents the outcomes of the metrics outlined in Section 1, providing both quantitative and qualitative evaluations divided into two assessment categories. In the first stage, we analyze the ROUGE, BLEU, and METEOR metrics that evaluate results at a syntactic level, analyzing words or sentences. In the second stage, we employ BERTScore and BERTopic metrics that leverage pretrained language models based on the BERT architecture for semantic-level text analysis, utilizing multilingual BERT models pretrained for Portuguese language analysis.

[2] https://ai.meta.com/llama/
[3] https://huggingface.co/blog/llama2

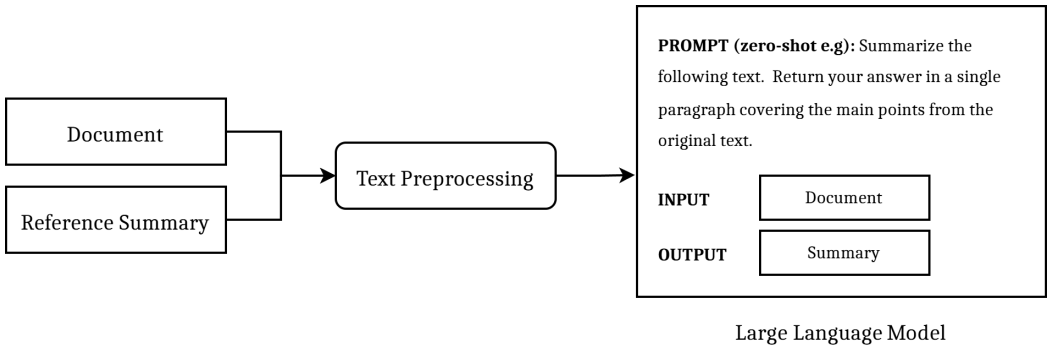

Fig. 1 – Text summarization pipeline architecture using a Large Language Model. The flowchart illustrates the complete process: (1) initial inputs consisting of the original document and its reference summary; (2) text preprocessing phase that normalizes and prepares the document for summarization; (3) the Large Language Model component featuring a zero-shot prompt, with clearly defined input (preprocessed document) and output (generated summary) pathways. The reference summary serves as an evaluation benchmark though this comparison is not explicitly shown in the diagram. This architecture was implemented using LLAMA2 as the underlying language model.

5.1. Structural Level Evaluation

This proposal utilized a set of ROUGE metrics (Lin, 2004) to evaluate lexical overlap between LLM-generated and reference summaries. Specifically, ROUGE-1 and ROUGE-2 measure unigram and bigram overlap respectively, while ROUGE-L assesses the longest common subsequence. An n-gram is a contiguous sequence of n items (typically words or characters) from a text, used as a basic unit of analysis in natural language processing to evaluate textual overlap in metrics such as ROUGE-1 and ROUGE-2 in summary quality evaluation.

The ROUGE metrics analysis reveals a consistent downward trend in LLM summarization performance over the 2013-2023 period, with all three measures (Unigram, Bigram, and L-score) showing peak values in 2013 (0.399, 0.319, and 0.346 respectively) and lowest values in 2023 (0.336, 0.260, and 0.290), representing a decline. All scores remained relatively low (below 0.4), which may reflect the considerable length disparity between reference summaries (31-35 words) and LLM-generated summaries (96-127 words) rather than actual quality deficiencies. The parallel patterns across all three metrics suggest that lexical overlap at different granularities is similarly affected by underlying factors such as increasing document complexity (606 words in 2013 to 1,057 words in 2023). These findings underscore the limitations of using lexical-based evaluation metrics for abstractive summarization tasks, particularly as legislative language evolves over time.

The *Bilingual Evaluation Understudy* (BLEU) (Lin & Och, 2004; Papineni et al., 2002) is a metric that was initially developed for the purpose of evaluating machine translation systems by comparing candidate translations to reference translations. Furthermore, it has gained relevance in other natural language processing tasks like assessing text summarization systems.

The BLEU score analysis for summarization reveals a consistent temporal decline from 2013 (0.173) to 2023 (0.140), representing a performance decrease. Despite minor fluctuations in 2018 (0.158) and 2021 (0.164), all scores remain notably low (below 0.18), with a year average of 0.149. This pattern parallels the increasing document length (606.2 to 1,057 words) over the same period, suggesting a potential correlation between source complexity and summarization difficulty. The substantial length disparity between reference (31-35 words) and LLM-generated summaries (96-127 words) further complicates interpretation, as BLEU primarily measures lexical precision without capturing semantic equivalence. These findings align with the study's position that traditional n-gram overlap metrics have inherent limitations for evaluating domain-specific abstractive summarization. LLMs may be predisposed to producing more verbose summaries than what human preferences might dictate. This observation suggests a promising avenue for future research, particularly in the realm of prompt engineering for summarization tasks. Notably, there exists a strong correlation ($R=0.96$) between the lengths of summaries generated by LLAMA2 and those of manual reference summaries. As the length of reference summaries increases, the model tends to generate proportionally longer summaries.

Tab. 2 – The table displays the evaluation results of the ROUGE, BLEU, and METEOR metrics. The "Year" column specifies the year of the text subset. The "Unigram score" and "Bigram score" columns represent the ROUGE metric values, calculated using unigram (1-gram) and bigram (2-gram) respectively, by comparing the generated summary with the reference summary. The "L-score" column shows the ROUGE metric value based on the Longest Common Subsequence, again comparing the generated summary with the reference summary. The "BLEU score" and "METEOR score" columns present the results for these two metrics.

Year	ROUGE			BLEU-score	METEOR-score
	Unigram-score	Bigram-score	L-score		
2023	0.336	0.260	0.290	0.140	0.459
2022	0.369	0.283	0.313	0.150	0.475
2021	0.384	0.305	0.330	0.164	0.500
2020	0.352	0.271	0.305	0.150	0.463
2019	0.360	0.279	0.311	0.150	0.473
2018	0.379	0.292	0.326	0.158	0.479
2017	0.360	0.275	0.304	0.145	0.466
2016	0.352	0.265	0.300	0.145	0.459
2015	0.348	0.258	0.293	0.142	0.452
2014	0.371	0.284	0.317	0.152	0.475
2013	0.399	0.319	0.346	0.173	0.511

METEOR (*Metric for Evaluation of Translation with Explicit Ordering*) (Banerjee & Lavie, 2005) is a metric initially developed for machine translation evaluation that has since been widely adopted for summarization assessment. METEOR evaluates similarity between generated and reference summaries by conducting recall analysis at multiple linguistic levels: exact matching, stem matching, synonym alignment, and paraphrase correspondence. In its scoring algorithm, METEOR assigns higher weights to exact token matches than to stems and synonyms, prioritizing precision in word choice over semantic approximations.

The METEOR evaluation shows scores ranging from 0.452 (2015) to 0.511 (2013), with a mean of 0.474 across the. Unlike the consistently declining pattern in ROUGE and BLEU metrics, METEOR exhibits more fluctuation, with a secondary peak in 2021 (0.500) before dropping to 0.459 in 2023. METEOR scores substantially outperform BLEU scores across all years, reflecting its design to capture semantic similarity through exact matches, stems, synonyms, and paraphrases rather than strict n-gram correspondence. The moderate absolute performance (scores 0.5) indicates that generated summaries capture approximately half of the reference content when accounting for lexical variations. This relatively stronger METEOR performance suggests LLMs produces summaries that maintain semantic fidelity despite using different terminology than human references. The overall temporal decline correlates with increasing document complexity, suggesting potential challenges in maintaining semantic precision as legislative texts grow more elaborate.

5.2. Semantic Level Evaluation

BERTScore (Zhang et al., 2020) was utilized to evaluate the summarization task, providing an assessment of the quality of generated summaries compared to reference summaries. As an automatic metric for text generation, BERTScore calculates a similarity score for each token in the candidate sentence against each token in the reference sentence. This calculation is performed using pre-trained contextual embeddings from BERT models, matching words in both sentences through cosine similarity. The implementation of BERTScore facilitates a comprehensive evaluation of summary quality by capturing semantic relationships beyond lexical overlap, ensuring that generated summaries are accurately compared to their reference counterparts.

BERTScore F1 values above 0.7 generally indicate strong semantic alignment. The range of 0.730-0.757 suggests that LLAMA2-13b produces summaries that capture approximately 73-76% of the semantic content in reference summaries—a reasonably strong performance. These scores significantly outperform the syntactic metrics as ROUGE and BLEU, highlighting BERTScore's ability to capture semantic rather than lexical similarity, which is particularly important for abstractive summarization. The consistently higher recall versus precision aligns with the observation that LLM summaries are longer than reference summaries. The model effectively captures the reference content but adds supplementary information. The declining trend correlates

with increasing document complexity (606 to 1,057 words), suggesting that maintaining semantic precision becomes more challenging as legislative texts grow more elaborate.

Overall, these results indicate good semantic alignment between LLM-generated and reference summaries, especially considering the inherent challenges of legal text summarization. The high recall values demonstrate the model's ability to identify and incorporate key semantic elements, though the precision gap reveals opportunities for generating more focused summaries. The relatively small variation in F1 scores suggests consistent performance despite increasing document complexity over the years.

Tab. 3 – BERTScore semantic evaluation of LLAMA2-13b generated summaries. The table presents yearly semantic similarity metrics between model-generated and human reference summaries. Precision measures how much of the generated content is relevant, Recall quantifies how much of the reference content is captured, and F1-score represents their harmonic mean.

Year	Precision	Recall	F1-score
2023	0.678	0.800	0.730
2022	0.693	0.813	0.747
2021	0.697	0.815	0.750
2020	0.685	0.804	0.739
2019	0.687	0.808	0.742
2018	0.694	0.802	0.743
2017	0.688	0.803	0.740
2016	0.684	0.798	0.735
2015	0.685	0.795	0.735
2014	0.694	0.806	0.745
2013	0.705	0.820	0.757

BERTopic is a topic modeling technique (Grootendorst, 2022) that utilizes pretrained BERT embeddings and class-based TF-IDF (*c-TF-IDF*) to generate interpretable topics and clusters from text. For this experiment, we generated topics for each reference summary (manually created), for summaries produced by the LLM model, and finally, for all topics present in the original text. The objective of this evaluation was to compare the capacity of each summary type to present the same topics identified in the original texts. Through this comparison, we aimed to determine which summary better represents the original text's information: the manual summary or the LLM-generated summary.

The results in Table 4 reveal that BERTopic produces topics that are on par with or superior to human reference summaries in a substantial number of cases, confirming its potential as an unsupervised topic modeling technique that leverages pretrained transformer models. The combined "LLM Wins + Tie" rate consistently exceeds 80% across all years, indicating that LLAMA2 summaries rarely perform substantially worse than human-crafted summaries in capturing topic alignment. For an unsupervised approach competing against human experts in a specialized domain (legislative texts), winning several of direct comparisons while maintaining topic parity in approximately almost of cases represents notable performance. The high tie percentage suggests that LLAMA2 has effectively learned to identify the most significant topics in legislative documents, which is particularly valuable for practical applications in legal information processing.

6. Conclusion

This research investigated the application of Large Language Models (LLMs) for abstractive summarization of Brazilian legislative proposals, examining a comprehensive dataset of over 56,000 texts spanning from 2013 to 2023. The study evaluated the performance of LLAMA2-13b in generating concise and informative summaries of complex legal documents, comparing them against human-created reference summaries using multiple evaluation metrics. The analysis presented provides insights into the capabilities and limitations of LLMs for summarizing legislative documents, particularly Brazilian legislative proposals. The research demonstrates that LLMs can effectively generate coherent and informative summaries of complex legal texts, though with varying degrees of alignment with human-crafted reference summaries depending on the evaluation metric employed.

Our investigation into traditional structural-based metrics such as ROUGE, BLEU, and METEOR revealed sig-

Tab. 4 – BERTopic semantic alignment comparison between reference and LLAMA2-13b generated summaries. The table presents the yearly distribution of topic modeling results using pretrained BERT embeddings and class-based TF-IDF (c-TF-IDF). "Ref. Wins" indicates cases where human-generated reference summaries exhibit stronger topic alignment with original legislative texts. "LLM Wins" represents instances where LLM summaries demonstrate superior topic correspondence. "Tie" shows the percentage of documents where both summary types maintain equivalent topic representation. Note the consistently high tie percentage (65.3%-74.2%) across all years, suggesting comparable semantic performance between human and AI-generated summaries.

Year	Ref. Wins	LLM Wins	Tie
2023	20.8%	17.1%	69.7%
2022	22.6%	13.6%	74.2%
2021	19.5%	15.7%	67.6%
2020	21.5%	18.7%	65.3%
2019	20.3%	16.6%	69.4%
2018	20.7%	16.9%	69.1%
2017	16.1%	13.8%	72.7%
2016	19.2%	15.5%	65.7%
2015	19.3%	18.2%	69.8%
2014	19.3%	15.5%	71.8%
2013	16.1%	13.3%	73.6%

nificant limitations in their applicability to abstractive summarization evaluation. These metrics consistently showed declining performance trends from 2013 to 2023, with ROUGE scores dropping from peaks of 0.399, 0.319, and 0.346 (Unigram, Bigram, and L-score respectively) in 2013 to 0.336, 0.260, and 0.290 in 2023. Similarly, BLEU scores decreased from 0.173 to 0.140, and METEOR from 0.511 to 0.459 over the same period. This decline correlates with the increasing complexity of legislative documents. However, the low performance on these traditional metrics appears to be significantly influenced by the substantial length disparity between reference summaries and LLM-generated summaries rather than actual quality deficiencies. This observation highlights a crucial limitation of lexical overlap-based evaluation for abstractive summarization, where semantic equivalence may exist without exact wording matches.

In contrast, semantic-based evaluation metrics provided more promising results. BERTScore analysis demonstrated strong semantic alignment between LLM-generated and reference summaries. The consistently higher recall versus precision values confirm that while LLM summaries effectively capture reference content, they tend to include additional information. This aligns with our observation regarding summary length differences and suggests that LLMs maintain good semantic fidelity despite using different terminology than human references. Perhaps most interestingly, the BERTopic analysis revealed that LLAMA2-13b generated summaries that were on par with or superior to human reference summaries in a substantial number of cases. The combined "LLM Wins + Tie" rate consistently exceeded 80% across all years, with high tie percentages. This indicates that the LLM can effectively identify and represent the most significant topics in legislative documents, which is particularly valuable for practical applications in legal information processing.

These findings position LLMs as efficient options for summarizing legal documents, with no significant difference between manually and automatically generated summaries in terms of topic representation. However, challenges remain in addressing the complexity of legal terminology and argumentative structures, and in developing evaluation methodologies that adequately assess semantic understanding and preservation of legal validity in generated summaries. Future work should focus on refining prompt engineering techniques to generate more concise summaries that better align with human preferences while maintaining semantic comprehensiveness. Additionally, developing specialized evaluation metrics for legal text summarization that account for domain-specific requirements would enhance the assessment of LLM performance in this context. Finally, exploring fine-tuning approaches specific to legislative documents could potentially improve summarization quality and address the observed performance variations over time.

In conclusion, this study demonstrates the promising potential of LLMs for legislative document summarization while highlighting the importance of semantic-level evaluation metrics in accurately assessing their performance. The results provide a foundation for further research into optimizing LLM applications in legal and

governmental domains where efficient information processing is increasingly crucial.

We sincerely appreciate the support provided by the research funding agencies CAPES, FAPESP, and CNPq, whose contributions have been essential to the development of this work. Furthermore, we extend our gratitude to the Brazilian Chamber of Deputies, the Center for Applied Research in Artificial Intelligence Recreating Environments (CPA IARA), and the Brazilian National Institute of Artificial Intelligence (IAIA) for their significant support in advancing this research.

Abstract. This paper aims to answer three main questions regarding the use of artificial intelligence (AI) tools in the Colombian judiciary. First, what type of AI tools do judges and judicial staff in Colombia access and use? Second, how and for what purposes are these AI tools used? Third, do demographic factors (e.g., age, gender) influence how judges and judicial staff approach AI tools? This paper is based on three comprehensive surveys conducted in 2024. Two surveys conducted by the authors targeted participants in the course "Artificial Intelligence for the Administration of Justice: Fundamentals, Applications, and Best Practices", offered by the Universidad de los Andes and the Superior Council of the Judiciary (CSdJ). A total of 1,391 judicial staff members responded at the start of the course, and 824 responded at its conclusion. A third survey, conducted later by the CSdJ, gathered responses from 3,152 judicial personnel. Our analysis reveals that training significantly improved AI familiarity among judicial personnel—initially, 63% reported minimal knowledge, but after the 50-hour course, 85% claimed moderate to high familiarity. While approximately one-third of respondents initially used AI for work tasks, this increased to nearly half post-training. Over 80% of users accessed free AI versions, raising concerns about confidentiality as these platforms may share information with third parties. Judicial officials primarily employ generative AI for information searches and document writing, particularly for jurisprudence (59%), legislation (52%), and definitions (51%). This reliance on AI for information retrieval presents risks if outputs aren't verified against reliable sources. Although age and gender disparities in AI familiarity exist, reported usage patterns show minimal demographic differences. These findings emphasize the importance of enhancing digital literacy among judicial professionals and inform our recommendations for developing appropriate regulations and guidelines governing AI systems in the justice sector.

1. Introduction

The adoption of artificial intelligence (AI) tools can contribute significantly to the objectives of the administration of justice and, in general, to the objectives of the States (UNESCO, 2023). Magistrates, judges and other judicial staff around the world have been using AI systems for the management of processes and support in performing legal tasks over the last decade (CEPEJ, 2024; Gutiérrez, 2020).

However, the successful adoption of these systems depends on multiple factors that go beyond the characteristics of the technological tools themselves and the physical infrastructure required for their operation. The

effectiveness of AI systems in solving problems or achieving objectives within an organization also depends on the human factor, at both the individual and organizational levels. In that sense, the human talent that deploys and uses them is essential, in addition to the governance of the organization and the culture that shapes the behavior of the individuals who compose it.

This paper aims to answer three main questions regarding the application of AI tools in the Colombian judiciary. First, what type of AI tools do judges and judicial staff in Colombia access and use? Second, how and for what purposes are these AI tools used? Third, do demographic factors (e.g., age, gender) influence how judges and judicial staff approach AI tools?

This is the most comprehensive article published to date on the use of AI systems in Colombia's public sector. The study is based on three surveys conducted among Colombian judicial personnel. The surveys were conducted in the first semester of 2024 through electronic forms. Two surveys were answered by judicial officials who took part in the course "Artificial Intelligence for the Administration of Justice: Fundamentals, Applications and Best Practices", offered jointly by the Universidad de los Andes and the Superior Council of the Judiciary (CSdJ) - the body in charge of governing the judiciary in Colombia. The first survey was answered at the beginning of the course by 1,391 judicial personnel, and the second at the end of the course by 824 judicial personnel. The third survey was administered directly by the CSdJ and answered by 3,152 judicial personnel. This paper, based on the survey data, explores the ways in which judicial personnel use AI tools, focusing on Generative Artificial Intelligence (GAI) systems.

The paper is divided into four sections, in addition to this introduction. The first section provides a brief literature review on empirical research that has examined how judicial operators worldwide use these tools. The second section details the methodology employed to conduct the research, emphasizing the design and processing of the surveys. Next, the third section outlines the main findings regarding the uses of the tools. The final section synthesizes the key findings from the surveys.

2. Literature review

The use of AI tools in the justice sector precedes the "boom" of GAI systems that detonated globally, in November 2022, with the launch of the ChatGPT tool by OpenAI. For example, since November 2017, the Prosecutor's Office of the Autonomous City of Buenos Aires, Argentina, has been using the Prometea system for "the digital automation of reiterative task processes and the application of AI for the predictive elaboration of legal opinions in analogous cases for whose solution there are already reiterative judicial precedents" (Estevez et al., 2020, p. 46). In Brazil, since 2019, the Federal Supreme Court (STJ) implements the Victor tool to support the review the admissibility of appeals concerning the requirement of "general repercussions" (Ministro do Superior Tribunal de Justiça, 2020; UNESCO, 2023).

The "Resource Centre Cyberjustice and AI" database, created by the Council of Europe's European Commission for the Efficiency of Justice (CEPEJ), lists over 140 different AI tools used by judges and courts on different continents. In Colombia, for example, since 2021 the Constitutional Court has been using the PretorIA tool, a machine learning system that assists in the search for information for the selection of tutelas in the review process (proceso de revisión) (Corte Constitucional, 2020, 2024; Gutiérrez, 2020; Gutiérrez & Muñoz-Cadena, 2023; Saavedra & Upegui, 2021).

More recently, there has been a growing interest in incorporating GAI systems into legal work by judges, prosecutors, and lawyers (Gutiérrez, 2024c; UNESCO, 2023). For example, (Gutiérrez, 2023a, 2023b, 2023c, 2023d, 2024a) has documented cases in which judges and courts have used chatbots operating from large-scale language models (LLMs) to support the drafting of judicial decisions and their participation in court hearings.

While there are case studies on specific AI tools deployed in the justice sector, such as those mentioned earlier, and monographs that document various types of AI tools, like (UNESCO, 2023), scholarship on how these tools are utilized in practice by magistrates, judges, and judicial staff remains limited. Only recently, an emerging literature has sought to understand the use of AI systems in the justice sector through surveys. The studies examine how judicial officers and lawyers utilize these systems in their professional roles. This section overviews the findings of four recent surveys conducted by the Conselho Nacional de Justiça do Brasil (CNJ), the United Nations Educational, Scientific and Cultural Organization (UNESCO), LexisNexis, and Thomson Reuters.

First, the Brazilian CNJ (Conselho Nacional de Justiça, 2024) studied aspects of the governance of the use of GAI systems in the judiciary and evaluated the impacts of these tools in the Brazilian judicial system. The results presented below focus on the second part of the survey regarding the use of these tools by the Brazilian judiciary. The questionnaire was sent to all active magistrates and judicial personnel between May and June 2024. The target population consisted of 16,844 magistrates and 278,755 judicial personnel. In total, responses were obtained from 1,681 magistrates (9.1%) and 16,844 judicial personnel (6%).

Due to the concern related to the reliability of the texts generated by GAI systems, the study inquired about the reasons for their use. The main uses of GAI tools identified by the survey correspond to text generation, proofreading, translation, and synthesis, among others. However, the results also highlight the use of these tools for tasks such as general information searches (approximately 50%) and case law searches (15% of magistrates and 11% of judicial personnel). When evaluating the potential uses of these tools, most magistrates (70%) and judicial personnel (60%) considered them helpful for case law searches, both for professional practice and research.

When asked about potential limitations to the use of these tools, the central reported limitation was a lack of knowledge in their use (51.9%), followed by distrust in the reliability of the results (32.6%), a lack of regulation (15%), and ethical concerns regarding their use (10%). These results are analogous to those found in the survey that we conducted in Colombia, particularly regarding the perceptions of magistrates, judges, and other judicial personnel on the barriers to the adoption of AI systems in the administration of justice in Colombia. However, the results of the Brazilian survey suggest that there is optimism in the use of these systems due to their potential benefits for various tasks (80% of magistrates and 70% of judicial personnel). In addition, more than 95% of those surveyed consider it appropriate to receive training in the use of GAI tools in the workplace.

Second, the survey conducted by UNESCO at the end of 2023 targeted its global network of judicial operators, including judges, judicial staff, prosecutors, lawyers, and legal researchers. In total, 563 judicial operators from 96 countries responded to the survey (Gutiérrez, 2024c). Among the main findings of the survey, 31% of respondents considered themselves "expert" or "very familiar" with AI systems, 41% answered that they were "moderately familiar" with AI, and 27% were somewhat or not at all familiar. On average, respondents reported greater familiarity with AI systems than the Colombian judicial personnel who responded to the survey at the beginning of the CSdJ Course.

The UNESCO study also identified that 44% of respondents reported having used AI tools in the work context, but half of these reported sporadic use (monthly or once). This proportion is lower relative to the average of those who responded to the Colombian survey at the start of the CSdJ course, but similar to those who responded to the exit survey. Among the main tasks for which GAI systems are used, according to the respondents of the UNESCO survey, were searching for information related to the justice sector, drafting documents, and exploring ideas. This pattern was similar to that found in the responses of the Colombian judicial personnel who were surveyed at the start and end of the CSdJ course.

Despite the widespread adoption of GAI tools, 69% of respondents to the UNESCO survey consider that there are risks associated with the use of these systems in the administration of justice due to the quality of the text generated, the potential violation of personal data protection law, potential copyright violations, and opacity in the operation of these systems, among others. In the case of the beginning and exit surveys of the CSdJ Course, the proportion of Colombian judicial personnel who identify potential risks is higher, but the types of risks identified are similar.

In third place, Lexis Nexis, a multinational business and legal information technology analytics company, conducted a survey of 4,180 lawyers, law students, and U.S. citizens (LexisNexis Legal & Professional, 2023). The objective of the survey was to better identify familiarity, usage, and adaptation of AI systems for legal matters. Among the main results, the respondents' familiarity with AI stands out. 98% of respondents under 45 years old and 82% over 45 years old are aware of the existence of these systems, despite being a relatively new technology. The survey also shows the gap between awareness of these tools and their use, both personally and professionally: 36% of lawyers reported using these tools, compared to 44% of law students and 32% of citizens.

When asked about the reasons for use, the main answers were research on various topics (59%), writing

documents (45%), writing emails (38%), and understanding new legal concepts. These results regarding the types of uses of the tools are similar to those found in the UNESCO global survey and in the surveys conducted in Colombia. Concerning the perception of impact, 29% of the lawyers considered it to be significant, and 10% viewed it as transformative. When asked about the type of impact, 15% believed it would be positive, 62% saw it as mixed (both positive and negative), 11% thought it would be negative, and 12% indicated that the impact is uncertain. In comparison, the judicial personnel who responded to the surveys in Colombia seemed to be slightly more optimistic about the future impact of these technologies.

Despite the potential uses reported by respondents, 87% of lawyers expressed concerns regarding the ethical implications of using these systems: somewhat (54%), very (29%), or significantly (4%). Both the UNESCO global survey and the Colombia surveys found a high percentage of people who believed that the use of AI tools in the justice sector posed risks and potential negative consequences. The answers to the open-ended questions were analyzed by Lexis Nexis with the assistance of AI systems. The results indicate that while lawyers see potential benefits from these systems, AI will not replace the human function in law. The primary concern expressed by respondents is the prospect of job losses.

Finally, Thomson Reuters, a multinational information and technology company, surveyed professionals in English-speaking countries across various sectors, including legal, tax and accounting, risk and fraud, as well as officials from government entities, to understand their perceptions of GAI tools and how they are being introduced in the workplace (Thomson Reuters, 2024). The sample for the survey was constructed from a company database. A total of 1,128 people were surveyed between January and February 2024. All respondents came from English-speaking countries such as the United States (48%) and the United Kingdom (19%), among others. Regarding the perceptions observed, 46% of the participants reported feeling hopeful and enthusiastic about the use of these tools, while 18% expressed worry or fear. Respondents from the justice sector were the most concerned (31%) and least enthusiastic (15%) of all participating sectors.

When asked whether GAI tools can be implemented in their fields of work, 85% of the respondents from the legal area answered in the affirmative. However, when answering the question of whether these tools should be implemented in their fields of work, 51% of respondents from the legal sector agreed. When delving deeper into the reasons why GAI tools should or should not be implemented in the legal sector, respondents perceived that these tools help save costs and increase efficiency in the use of workers' time in high-value tasks. However, the legal sector workers surveyed also identified two of the main reasons why they did not consider it appropriate to use GAI tools: the lack of reliability and accuracy of the answers provided.

When exploring expectations regarding the use of GAI systems, a significant gap can be observed in Thomson Reuters' survey. Specifically for the justice sector, only 14% of organizations report that they use these tools, 12% plan to use them, 35% are considering their use, and 40% have no current plans to use these systems. Respondents were also asked about barriers to adopting these tools, and the primary concerns raised by them included the potential risk of inaccurate information (70%), worries about data security (68%), and the privacy and confidentiality of information shared with GAI systems (62%). These results are similar to those identified in the responses to the questions on the risks associated with the use of GAI in the justice sector in the UNESCO global survey and the surveys in Colombia.

As observed in this literature review, the interest in understanding the use of AI systems in judicial systems globally is growing. This trend motivates the present research to examine their adoption, implementation, perceptions, and ethical and legal implications in Colombia. The four major surveys (Conselho Nacional de Justiça, 2024; Gutiérrez, 2024b; LexisNexis Legal & Professional, 2023; Thomson Reuters, 2024) indicate that a significant percentage of people have begun to implement AI tools in the justice sector, and the share of judicial personnel who report using AI tools appears to be increasing. Additionally, in contrast to the optimism about the potential improvement in efficiency and productivity that dominates the narratives of tech companies and some policymakers, the surveys suggest that there is concern about the lack of regulation, low access to formal training, and the potential risks associated with the inappropriate or malicious use of these systems.

This research aims to contribute to the literature by analyzing the use of AI systems by magistrates, judges, and other judicial staff in Colombia. Our findings highlight the importance of enhancing digital literacy among professionals who use AI systems in the administration of justice. Based on these findings, our article offers insights and recommendations for future regulations and guidelines regarding the use of AI systems in the justice sector.

3. Methodology and Data

This research is based on three surveys conducted with judicial personnel in Colombia about the uses and governance of AI tools in the justice sector. The authors conducted two surveys as part of the CSdJ Course delivered by Universidad de los Andes between January and May 2024, and a third survey was administered directly by the CSdJ at the beginning of the second semester of 2024. The CSdJ considered the questions from the first two surveys, replicated some of them, and created its own questionnaire. The survey delivered by the CSdJ was sent to all judicial servants, allowing them to independently respond if they had attended the CSdJ Course.

The two surveys administered as part of the CSdJ course mirrored the UNESCO global survey but included additional questions, such as the perceived barriers to adopting AI tools by the judiciary. The questionnaires of the two surveys included open and closed questions focusing on three areas of interest: familiarity with and uses of AI systems, perceptions of the implications of their usage, and governance of AI tools. First, about familiarity and uses, the questions included the frequency of use in work environments, the reasons why judicial personnel use these systems, and how they access these systems. Second, regarding the implications of using AI tools, judicial personnel were asked about the perceived risks and negative aspects of AI systems, as well as their views on the potential impact of these systems on society and the justice sector. Finally, regarding governance, the questions addressed the perception of barriers to adoption, training for using these systems, best practices, and current regulations governing these systems. The analysis of the last two types of questions, regarding potential risks and AI governance, is not included in this paper due to space constraints and will be addressed in future publications.

Due to the different number of responses, we compare the relative frequencies of the main sociodemographic variables between baseline (1.311 responses) and endline (824 responses). As presented in Table 1, there are no differences in the relative frequencies by sociodemographic variables, which helps in the comparison among the surveys conducted as part of the CSdJ Course by the Universidad de los Andes.

Tab. 1 – Sociodemographic characteristics of participants at baseline and endline.

Sociodemographic variables		**Baseline**	**Endline**
Gender	Male	44.14%	46.05%
	Female	55.50%	53.58%
	Prefer not to answer	0.36%	0.36%
Position	Judge	19.00%	23.67%
	Magistrate	12.50%	11.04%
	Other judicial staff	68.51%	65.29%
Age range	Under 26 years old	1.73%	1.33%
	26–35	24.19%	24.76%
	36–45	35.55%	36.53%
	46–55	25.77%	25.24%
	56–65	11.42%	11.29%
	Over 65 years old	1.29%	0.73%
	Prefer not to answer	0.07%	0.12%

Notes: Percentages may not sum to exactly 100% due to rounding.

3.1. CSdJ Course Surveys

The CSdJ Course taught the fundamentals of AI for the administration of justice to personnel in the Judicial Branch of Colombia. The course examined how various AI technologies are utilized by the judiciary across different jurisdictions, their potential benefits and risks, and avenues for preventing serious risks such as the violation of fundamental rights. The primary objective of the course was to develop and strengthen competencies for the responsible use of AI systems in the administration of justice.

The course comprised 18 class sessions organized into three modules: 1) Fundamentals of AI, 2) Applications in the justice sector and ethical framework for the use of AI, and 3) Good practices in the implementation of AI systems within the justice sector. In total, each student had the opportunity to have 50 hours of training: 35

in remote and synchronous sessions (through the Zoom platform) and 15 in asynchronous sessions (through Bloque Neón, the digital platform of the Universidad de los Andes).

The course was attended by 1,400 students who voluntarily registered following the call for applications issued by the CSdJ in December 2023. The students who registered for the CSdJ Course represented almost 4% of the total number of judicial officers in the country. The CSdJ established the following requirements for pre-enrollment in the course: 1) To be an employee of the Judicial Branch, with a continuous relationship of no less than three years; 2) Not to have a disciplinary record and 3) To have complied with the academic activities to which he/she has been previously admitted.

Participation in the course was balanced in terms of gender; 54% of the students were female (767) and 45% were male (633). Thirty-seven percent of the students who participated in the CSdJ course were between 36 and 45 years of age, followed by 24% of students between 26 and 35 years of age and 24% between 46 and 55 years of age. The remaining percentage of students belonged to a different age group. Thanks to the virtual format of the course, students from 138 municipalities in the country, located in 27 of Colombia's 32 departments, in addition to the capital, Bogotá, were able to participate (Figure 1a). Bogotá stood out as the city with the highest judicial personnel participation (341), followed by Medellín (81) and Cali (52).

As part of the activities implemented during the CSdJ Course, participants were asked to answer a survey at the beginning of the course (after being introduced to basic concepts of AI, such as what an AI tool is) and another one at the end of the course. The baseline survey was answered by 1,391 students (99% of registered judicial personnel), while the endline survey obtained 824 responses (58% of registered judicial personnel). One reason for the lower response rate in the endline survey is that completing the questionnaire was not mandatory for course certification, and by the end of the course, some students may have been less willing to participate voluntarily. Despite repeated efforts to distribute the questionnaire, the responses could not be matched to those from the baseline survey.

3.2. Survey administered by the CSdJ

The third survey was directly administered by the CSdJ between July 11 and 26, 2024. The CSdJ's survey was answered by 3,152 judicial officers throughout the country (Figure 1b). In this sense, more than 8% of Colombia's judicial personnel responded to this survey conducted by the CSdJ. The survey inquired about the use of AI systems, the perception of relevant AI regulatory guidelines, and the perceived ethical risks associated with the use of such systems.

(a) Number of students who participated in the CSdJ Course by department.

(b) Number of judicial personnel who responded to the CSdJ survey by department.

Fig. 1 – Location of judicial personnel participating in the CSdJ Course (left picture) and judicial personnel who responded to the CSdJ survey (right) by Department.

As can be seen in figure 1b, Bogotá presents the highest frequency of judicial officers who responded (689); Antioquia is the territorial jurisdiction with the second highest number of judicial officers (496). On the other hand, there were no responses from judicial officials in three departments of the country: Guainía, Vaupés and Vichada.

3.3. Survey data processing

Most of the questions in the three surveys provided multiple options for the judicial officers to choose from. These responses were sorted, and the resulting databases were organized to obtain basic descriptive statistics and generate various visualizations to represent them. The surveys also included some open-ended questions in order to better understand and analyze the multiple-choice answers provided by the participants. The open-ended questions analysis is not included in this paper due to space constraints and will be addressed in future publications.

4. Main Findings

4.1. Familiarity with the AI systems of judicial personnel.

To evaluate the use of AI systems and their various aspects, we chose to compare the results of the initial measurement conducted on the participants of the CSdJ Course with those of the final measurement. It is pertinent to mention that the judicial staff responded to the first survey after being exposed to basic concepts, such as what an AI system is, while the second survey was completed by the end of the course when students had finalized 50 hours of training. Where information was available, the results were compared with those obtained from the survey directly administered by the CSdJ. To facilitate the comparability of the results before and after, we chose to analyze the relative frequencies.

As shown in Figure 2, at the end of the course, the perceived familiarity with AI systems increased. Before starting the training, 63% of the trainees indicated that they had no or little knowledge of AI systems; this result contrasts with the 85% of trainees who indicated that they had moderate or a great deal of familiarity with these systems at the end of the course. It is worth noting that, at the end of the training, the percentage of older judicial personnel who perceived themselves to be experts in the use of AI systems did not change. As mentioned before, the level of familiarity with AI systems perceived by judicial officers in Colombia is relatively lower than that reported by judicial operators responding to the UNESCO Global Survey.

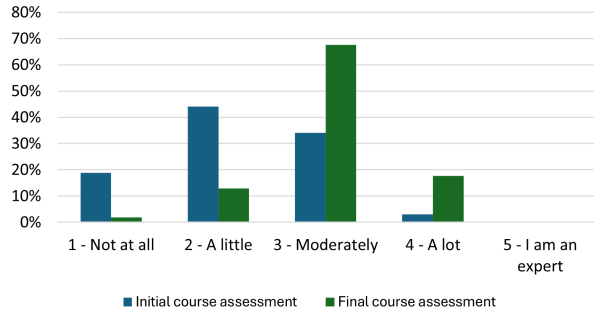

Fig. 2 – Familiarity with AI systems of judicial personnel (comparison before and after the CSdJ Course).

To evaluate the variations of relevant questions according to demographic variables such as gender and age, as well as the frequency of AI system usage, the differences observed exclusively in the entry survey of the CSdJ Course were compared using relative frequencies. First, with respect to the gender of the participants, it is observed that women responded having no or little familiarity with AI systems to a greater extent than men; for their part, men who indicated having moderate familiarity with these systems are 38% of the total, compared to 30% of women; finally, the minority of respondents indicate having a lot of knowledge or being experts in the use of AI systems (Figure 3).

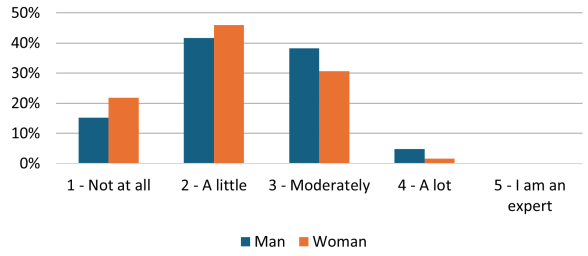

Fig. 3 – Comparison by gender of the familiarity with AI systems of judicial officers who participated in the Course.

When comparing familiarity with AI across different age ranges of the respondents in the CSdJ Course entry survey, several aspects stand out (Figure 4): Generally, it is observed that as age increases, the level of null familiarity with these systems rises; this relationship is inversely related to moderate familiarity. Therefore, it is noted that older judicial personnel tend to have less familiarity with AI systems.

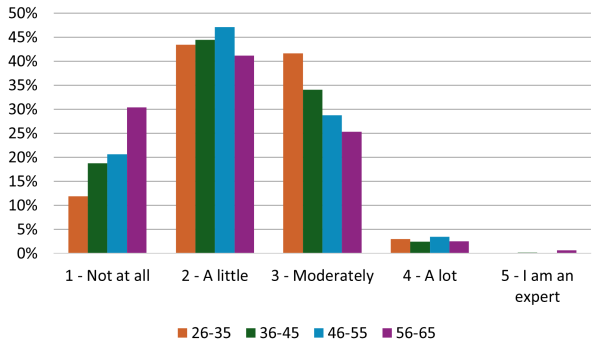

Fig. 4 – Comparison by age range of the familiarity with AI systems of the judicial officers who participated in the CSdJ Course. Observations for judicial personnel under 26 and over 65 are omitted since together they represent less than 2% of the data.

4.2. Uses of AI systems by judicial personnel.

The survey administered by the CSdJ asked judicial personnel if they had used "any AI tool or application that helps you make your job easier or faster." 29% of those who responded to the survey answered affirmatively (920 judicial personnel).

The two surveys conducted as part of the CSdJ Course also asked about the use of AI and GAI tools. At the beginning of the course, 34% of the trainees reported having used some AI tool for work purposes, and 26% reported having used GAI tools for the same purposes (Figures 5 and 6).

These data suggest that the learners who enrolled in the CSdJ Course and answered the course's baseline survey tended, on average, to be slightly more likely to use AI tools at work than the judicial personnel who answered the survey directly administered by the CSdJ. This observation is likely because students in the CSdJ Course had a greater interest in these tools, which is why they enrolled in the course (in short, a self-selection factor may contribute to explaining the different results). As mentioned before, these frequencies of use reported by judicial personnel in Colombia are somewhat lower than those reported by judicial operators who responded to the UNESCO global survey.

At the end of the CSdJ Course, the percentages reporting the use of AI systems for work-related issues increased significantly: 56% for any AI tool and 44% for GAI tools (Figures 5 and 6). These results suggest that the CSdJ Course may have influenced a significant number of students to use AI tools in their work for the first time and that lacking basic training is a barrier to testing and adopting these types of tools for work purposes.

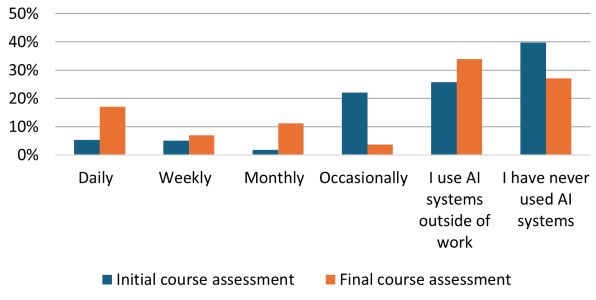

Fig. 5 – Frequency of use of AI systems (comparison before and after the CSdJ).

When studying the frequency of use of AI systems before and after the CSdJ Course, an increasing trend in use was observed after the course (Figure 5). Specifically, before the CSdJ Course, 39% of the trainees had never used AI systems, while this percentage dropped to 27% after the course. Similarly, the percentage of judicial personnel who began to use these systems in areas other than the workplace increased, as indicated by the students' responses, which showed an approximately 8% rise after the CSdJ Course. The greatest variation was observed in the percentage of trainees who used AI systems daily. Before starting the CSdJ Course, only 5% reported using these systems daily, compared to 17% at the end of the course. The percentage of judicial

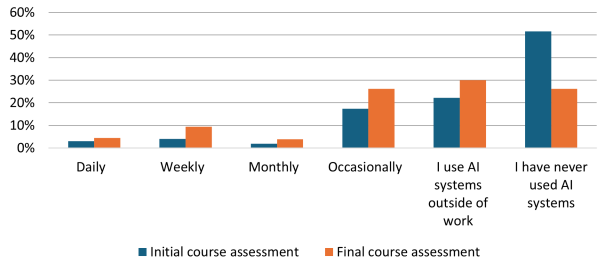

Fig. 6 – Frequency of use of AI chatbots (comparison before and after the CSdJ).

officers who started using these systems on a weekly and monthly basis also increased at the end of the CSdJ Course.

A similar pattern is observed with respect to the frequency of use of GAI systems (AI chatbots) to perform work activities (Figure 6). Before starting the CSdJ Course, 52% of judicial personnel reported never having used GAI systems, while at the end of the course, this figure dropped to 26%. The largest increase in reported use of AI chatbots after the CSdJ Course was for occasional use for work activities, which rose from 17% to 26%. To a lesser extent, daily, weekly, and monthly work-related use also increased after the CSdJ Course.

On the other hand, when comparing the frequency of AI system use by men and women, the largest difference lies in the reported lack of experience using these tools. Specifically, 35% of men reported never having used AI systems, compared to 44% of women. Regarding the frequency of use of AI systems for work purposes, most of the responses reported by men and women (daily, weekly, and occasional use) were relatively similar (Figure 7).

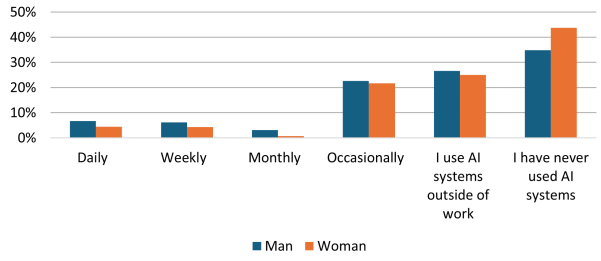

Fig. 7 – Comparison by gender of the frequency of use of AI systems by the judicial officers who participated in the Course.

In addition, when comparing the variations in the frequency of use of AI systems by age range, it is observed that, for each age range, approximately 40% of judicial personnel stated in the CSdJ Course entry survey that they had never used AI systems (Figure 8). Regarding all frequencies of use of AI systems for work tasks, there are no differences greater than 6% between age ranges.

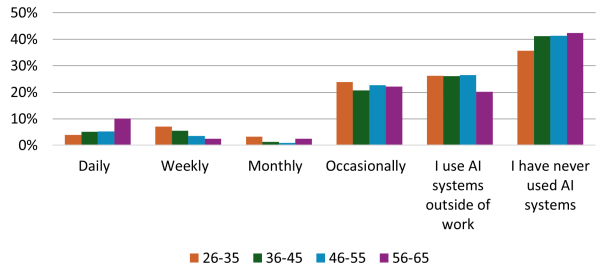

Fig. 8 – Comparison by age range of the frequency of the use of AI systems by judicial officers who participated in the CSdJ Course. Observations for judicial personnel under 26 and over 65 are omitted since together they represent less than 2% of the data.

However, these differences are mainly observed when comparing 26 to 35 years age group with the 56 to 65 years age group. In this regard, 10% of the judicial personnel between 56 and 65 years of age reported using AI systems daily, compared with 4% of those between 26 and 35 years of age. In this case, only 20% of judicial personnel aged 56 to 65 reported using these tools outside of work, while 26% of all other judicial personnel reported using these tools outside of work.

In sum, although, on average, younger trainees tended to report a greater familiarity with AI systems than older trainees, the propensity to use AI systems for work purposes does not diverge much between the age ranges of the judicial officers who responded to the CSdJ Course start-up survey.

4.3. What AI systems are used in the Judicial Branch?

In addition to identifying the main reasons for using AI systems, participants in the CSdJ Course were also asked about the specific systems they use in their professional activities. The word cloud (Figure 9) illustrates the AI tools most frequently mentioned by the respondents. Notably, *ChatGPT* (128 mentions) emerged as the most cited tool, with a frequency three times higher than that of the second most mentioned tool, *Copilot* (56 mentions). All other tools received fewer than 16 mentions, with *Gemini* (16 mentions), *Microsoft* (7 mentions), and *SAMAI* (5 mentions) standing out.

Fig. 9 – AI systems most commonly used at work by judicial officers who participated in the Course.

It should be noted that *SAMAI* is not currently considered an AI tool. Rather, it is a digital platform used within the contentious-administrative jurisdiction, offering functionalities such as online consultation of judicial case information, document authenticity validation and verification, and virtual document filing.

The survey conducted directly by the CSdJ also included a closed-ended question regarding the tools used by judicial personnel (Figure 10). Unlike the open-ended format used in the Course questionnaire, this version asked respondents to select tools from a predefined list. Nonetheless, the findings were consistent with those from the Course responses. *ChatGPT* was again the most frequently selected tool, with twice the number of mentions as *Copilot* (Microsoft), the second most used tool, followed by *Gemini* (Google) and *Bing* (Microsoft).

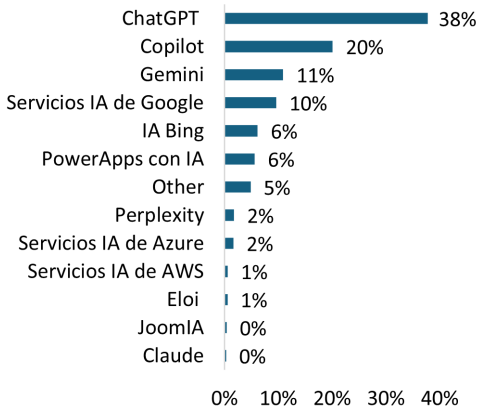

Fig. 10 – AI systems used by judicial personnel who responded to the CSdJ's surveys.

4.4. How are GAI systems being used in the Judicial Branch?

In the three surveys, judicial personnel were asked about their use of GAI systems to carry out professional activities. The question was presented in a multiple-choice format (with predefined subcategories of use), but allowed judicial personnel to add other types of uses if deemed necessary.

Figure 11 presents the most common uses reported by survey respondents: searching for caselaw (59%); searching for legislation (49% to 52%, which increased after completing the course); searching for meanings and definitions (increased from 46% to 51% by the end of the course); other uses (42% to 47% by the end of the course); and summarizing texts (40% to 41% by the end of the course) are the primary reasons judicial personnel utilize GAI systems.

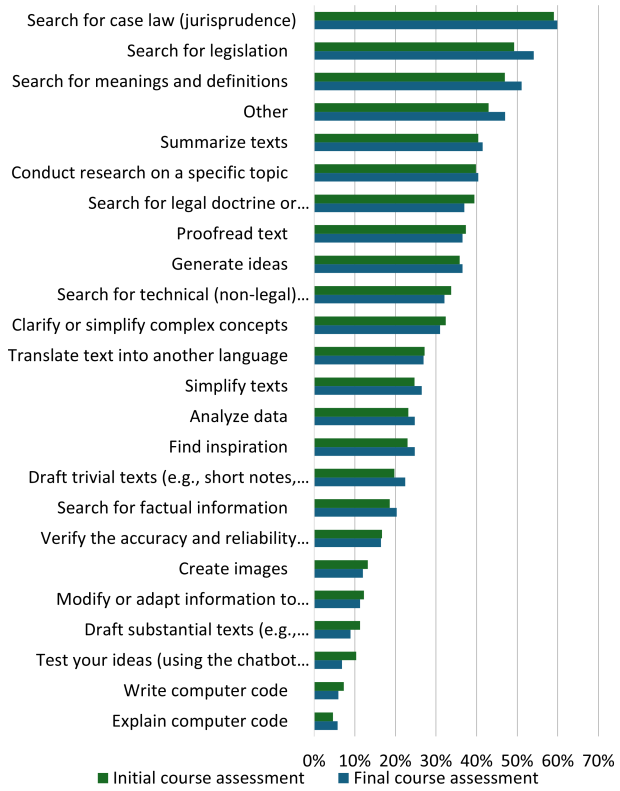

Fig. 11 – Uses of AI chatbots for work activities reported by judicial personnel (before and after the CSdJ's course).

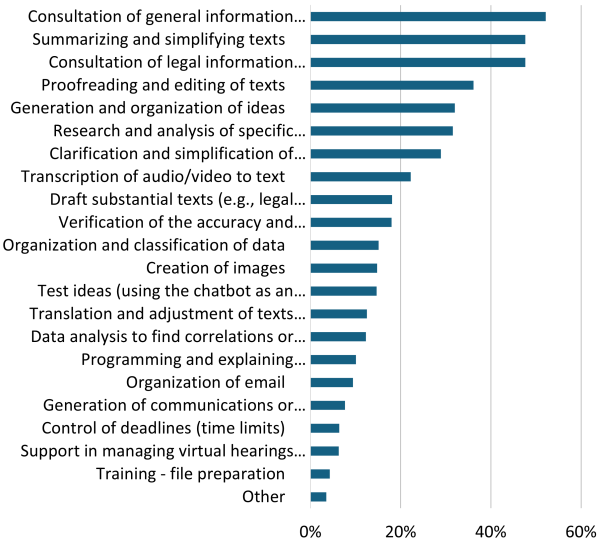

Fig. 12 – Uses of AI chatbots for work activities reported by judicial personnel who responded to the survey conducted directly by the CSdJ.

There is no major variation in the order of the most frequent uses reported by the students; however, in most cases, there is a slight increase in the reporting of each respective use, suggesting that the CSdJ Course may have diversified the types of uses to which judicial personnel apply AI chatbots. Additionally, a significant percentage of respondents indicated "other uses" apart from those listed in the survey question, highlighting the importance of further research into the potential applications that judicial personnel make of these tools.

Regarding the results of the survey conducted directly by the CSdJ (Figure12), the most common work uses that judicial personnel assign to AI chatbots were: consulting general information (52%), consulting legal information (48%), summarizing and simplifying texts (48%), proofreading and editing texts (36%), and generating and organizing ideas (32%).

The CSdJ Course surveys also sought to identify how learners used the responses generated by the AI chatbots. A very low percentage of respondents answered that they used the chatbot-generated response "without any verification or correction" (between 4% and 1% before and after the course, respectively). The vast majority of court judicial personnel either verify or correct the information before using it or use it to understand the issue and then formulate their own text (Figure 13). This result is similar to the one reported in the UNESCO global survey.

The main difference observed in the measurements at the beginning and end of the CSdJ Course is that the total number of judicial personnel that report verifying and correcting the information provided by the chatbots increases by 11 percentage points. This variation decreases by 8 percentage points with respect to the rate of judicial personnel who report using the information to learn and understand the information provided.

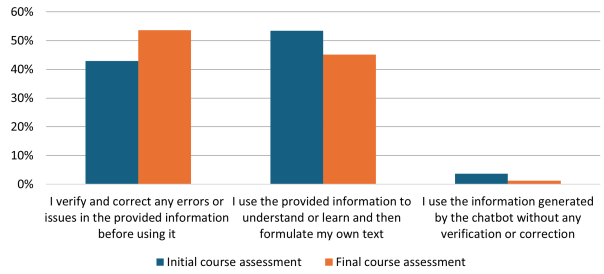

Fig. 13 – Form of use of the results generated by the chatbots (comparison before and after the CSdJ course).

When studying the responses on how the chatbots' results are used, distinguished by gender, it is observed that 56% of women reported using the information received to analyze it and better understand the context, compared to 50% of men (Figure 14). For both genders, less than 5% reported the information from the chatbots without any verification or correction, but it is worth highlighting that the proportion of women reporting this practice was half that of men.

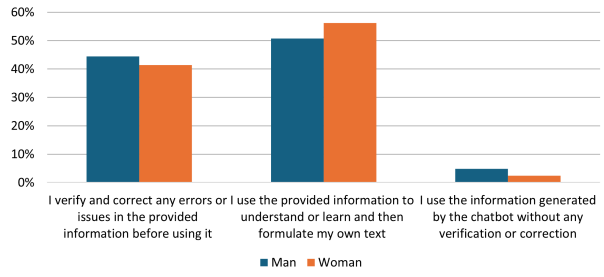

Fig. 14 – Comparison by gender of form of use of the results generated by the chatbots.

When comparing the results of chatbot usage by age, no significant differences were observed among the age groups. However, students aged 56 to 65 reported that they utilized the information to a greater extent (66%) for understanding or learning while also indicating that they wrote their own texts.

5. Conclusions

This research sought to answer fundamental questions about how judicial personnel in Colombia use AI systems in their work. The study was based on three surveys conducted among various types of judicial personnel in Colombia between January and July 2024. The first survey was completed at the beginning of the CSdJ Course by 1,391 judicial personnel, the second upon completion of the course by 824 judicial personnel, and the third survey, administered directly by the CSdJ, involved 3,152 judicial personnel. These are the largest surveys conducted to date in Colombia on the subject and among the largest in the world.

In this section, we synthesize the main findings of the surveys and reflect on the policy implications derived

from these findings, which are primarily relevant to the Colombian Judicial Branch but may also provide insights for organizations that govern the Judicial Branch in other countries.

5.1. Familiarity with AI systems

The familiarity with AI systems exhibited significant changes before and after completing the CSdJ course. In general, the percentage of learners with moderate or high knowledge of AI systems increased (85%). This degree of familiarity is lower compared to that evidenced by the judicial personnel who responded to the CSdJ survey. Concerning gender, women showed lower familiarity with these systems compared to men. When comparing age, there was a higher proportion of null familiarity among the older age range.

These findings suggest that awareness among judicial staff regarding the existence and relevance of AI tools is high even though the availability and access to tools such as AI chatbots proliferated relatively recently, in late 2022. Moreover, awareness is expected to increase as the adoption of these technologies is a priority in many jurisdictions, including Colombia.

5.2. Use of AI systems

Regarding the use of AI systems, 29% of the judicial officers who responded to the CSdJ survey indicated that they had used them to facilitate their work. This is in line with the percentage of students who took the CSdJ course and reported using AI systems (34%) and GAI (26%) for the same purposes before starting the course. Furthermore, at the end of the course, the use of these AI tools (55%) and GAI (43%) increased considerably. This suggests that one of the main barriers to using AI tools to support labor-related activities is a lack of basic training, such as understanding how these tools are developed, what types of tools are available, their limitations, and associated risks (key topics addressed in the 50-hour CSdJ Course).

Similarly, the frequency of AI system usage increased by the end of the course; the percentage of judicial personnel who had never used AI systems dropped from 39% to 27%, and for GAI systems from 52% to 26%. Moreover, the daily use of AI tools rose from 5% to 17%. This suggests that basic training on the use of AI tools can increase not only the likelihood of using the tools but also the frequency of use, thereby enhancing the impact (both positive and negative) of AI in the administration of justice.

Moreover, the tendency to use AI systems for work purposes does not vary significantly across the age ranges of the judicial personnel who responded to the CSdJ Course survey. This finding challenges the notion that younger workers are more likely to use AI tools than their older co-workers. However, participants in the CSdJ Course survey may be more likely to use AI tools than the judicial staff who did not take the course since their enrollment in the training was voluntary and may signal their original interest in using the tool regardless of their age or gender.

The findings also challenge the notion that members of the judiciary are generally resistant to innovation or reluctant to change the way work is conducted. Moreover, the fact that 1,400 magistrates, judges, and judicial staff voluntarily enrolled in a 50-hour AI course signals the demand for learning about new tools.

5.3. Access to AI systems

The majority of students who responded to the CSdJ baseline and exit surveys indicated that they accessed free versions of AI tools, whereas fewer than 20% paid for access to AI systems or indicated that the Judicial Branch provided the tools. This has important implications regarding the security of the information and, consequently, for the protection of privacy and personal data. Most companies that offer free versions of AI chatbots state in their terms of use that the information provided by users may be used for future training of models and that it may be shared with third parties (Gutiérrez, 2024a). Therefore, the use of these types of tools by judicial officials can jeopardize the confidentiality of information related to the judicial process and put fundamental rights at risk.

A key implication of this finding is that the judiciary needs to take action to prevent information breaches through a combination of human, technical, and administrative measures. These measures include prohibiting the use of generative AI tools that are offered for free or specifying which AI tools can be used (these can

take the form of rules or technical solutions, such as blocking access to the tools on institutional devices); alternatively, mandating that any information and documents introduced into these AI systems are anonymized and free from reserved data; providing alternatives for judicial staff to access generative AI tools that offer higher levels of information security and personal data protections; and, lastly, enhancing basic digital literacy skills through training programs.

In the case of the Colombian judiciary, some of these measures were taken by the end of 2024. Through the Agreement PCSJA24-12243 of December 16, 2024, the CSdJ adopted its guidelines "for the respectful, responsible, safe, and ethical use and exploitation of artificial intelligence in the Judicial Branch." The guidelines established "security of information" and "personal data protection and privacy" as two of the principles that must be abided by when using AI tools (article 1) and established that judicial personnel should "abstain from using general or commercial AI chatbots in its free versions" (article 8.1).

5.4. Reasons for using AI systems

The reasons for using AI systems among the judicial staff are diverse. Among the main reasons, five main categories were identified: systematization, writing, learning, idea generation, and analysis. Regarding the tools with the highest frequency of use by CSdJ Course participants, ChatGPT was the most frequently mentioned tool, followed by Copilot and Gemini. This result is similar in order of hierarchy to that observed in the responses of the judicial personnel who answered the survey administered by the CSdJ. However, the reported use of AI tools in the Colombian judiciary may have changed in 2025 due to the prohibition on using the free version of AI chatbots established by Agreement PCSJA24-12243, and because Copilot Chat is now available for Microsoft 365 business customers.

The survey's findings also highlight the need for the Colombian judiciary to provide a more diversified set of AI tools that are accessible to all or most of its judicial staff. Following the example of other Latin American jurisdictions, such as tools for assisted search of case law available for judicial staff and the general public (in late 2024, the Constitutional Court of Colombia launched such a tool for constitutional case law); automatic classification of documents submitted in judicial processes and assignment of those documents in workflows; anonymization tools; editing and summarizing AI tools; translation tools, both for text and live verbal translation; and tools for transcribing audio recordings of hearings (Muñoz-Cadena et al., 2025).

5.5. How GAI systems are used

When evaluating how the students of the CSdJ Course used GAI tools, the survey suggests that the highest priority was given to tasks related to information search and document writing, in that order. The result was similar to that shown in the survey conducted directly by the CSdJ, with the difference that document writing emerged as the most relevant category, followed by information search. These results align with the findings of UNESCO's Global Survey on the use of AI tools by judicial operators. When evaluating specific tasks, searching for jurisprudence remained unchanged at 59% after completing the course; searching for legislation increased from 49% to 52% after completing the course, and searching for meanings and definitions rose from 46% to 51% after completing the course, representing the main functions that CSdJ Course students assigned to these tools.

The predominant use of GAI tools to search for information generates additional risks, especially considering that most respondents access free versions of the systems. Given that there is a high probability that the answers provided by AI chatbots are imprecise, incorrect, or even false, a judicial official who does not contrast these outputs with reliable sources may make baseless decisions. (Gutiérrez, 2024a) has already mapped situations in which justices used AI chatbots in Bolivia, Brazil, Colombia, Peru, and Mexico to draft rulings and intervene in judicial hearings by copy-pasting answers or reading them out loud without checking on the reliability of the chatbot's output.

Moreover, the survey highlights the limitations of AI training in shaping the practical application of AI tools. While the CSdJ Course stressed the limitations of AI chatbots to participants, and even though the surveys indicated that the judicial staff were aware of the quality issues of AI chatbots, they still used them as a tool for searching for information. A policy implication from this finding is that the Judiciary cannot rely on a single type of action to ensure the responsible use of AI tools (e.g., training); it needs to complement various technical and regulatory measures.

5.6. Limitations and future research

Our research has several limitations, and there are potential future avenues of inquiry. First, the respondents of the three surveys were not selected randomly, nor were specific measures taken to ensure the representativeness of the samples. For example, the judicial staff that self-enrolled in the CSdJ Course and answered the corresponding start and end-line surveys were likely more interested in AI tools than their average peers, making them more prone to report higher and more diverse use of AI tools. Moreover, the design of the surveys did not allow for the identification of the effects of the training since there were no treatment and control groups.

Second, while the surveys allow for the identification of specific trends among the respondents, another data collection strategy—such as semi-structured interviews—would be necessary to understand why such trends arise and to provide a deeper interpretation of the survey results. Furthermore, this paper did not address other important aspects of AI tool deployment and usage in the justice sector, including specific perceptions of the risks associated with using AI tools and the need for AI governance arrangements. While the CSdJ Course surveys included questions on these topics, due to space constraints, we could not discuss them in this paper.

Finally, future research could explore in-depth cases of specific AI tools used by the judiciary in Colombia to understand how they are (or are not) changing labor roles and occupations within the judiciary and their impact on particular tasks, such as case management, decision-making processes, and drafting rulings.

Acknowledgement

The authors of this paper would like to thank the Superior Council of the Judiciary for allowing access to the anonymized data from the survey of Judicial Branch employees.

Track 11: GovTech and Digital Autonomy

Track Description

Governments no longer hold monopolies on designing and delivering digital solutions for the public sector. Under the GovTech label, startups, scaleups, and multi-helix initiatives are pounding at the gates with digital solutions built on state-of-the-art technologies. Examples include AI-based digital assistants for citizens and public professionals, digital identities, data wallets, and digital twins. Institutions such as the World Bank and the World Economic Forum have highlighted the significance of the rise of GovTech across both developing and developed countries. The European Commission stimulates GovTech development through the Interoperable Europe Act, a public-private collaboration for digital transformation in the public sector. While there are opportunities in embracing GovTech, risks include long-term stability, transparency, and safety. Considering current geopolitical tensions, the lack of strategic digital autonomy is also becoming a growing concern. Many public agencies depend on a few BigTech corporations for critical processes. This dependence can hamper the implementation of new policies, impede innovation, and promote problematic vendor lock-in. Digital autonomy is multi-dimensional, and policymakers struggle to shape adequate instruments. So, the track aimed to gather studies on the opportunities, risks, and potential mitigation strategies, and showcase GovTech and digital autonomy developments worldwide.

Abstract. The growing dominance of large technology companies in Europe's digital markets raises concerns about innovation concentration, limited competition, and reduced technological sovereignty. Public procurement represents a powerful yet underutilized instrument to address these dynamics by enabling smaller firms to compete, innovate, and scale within critical sectors. This study examines how public procurement can strengthen innovation capacity and economic diversity in the European information and communication technology sector. Focusing on the participation of startups and small businesses, we provide large-scale empirical evidence on structural barriers and market concentration in cross-border procurement practices. Our study reveals that public procurement systems often reproduce existing power asymmetries, despite policy ambitions to foster inclusivity and competition. Our findings highlight the significance of procedural complexity, limited outreach, and insufficient institutional capacity as key obstacles to startup participation. Moreover, we show that small and medium sized companies are far from homogeneous, necessitating targeted policy responses rather than uniform support measures. By framing startup inclusion as a systemic condition for innovation and digital sovereignty, the study contributes to ongoing theoretical debates on demand-side innovation policy and strategic governance. It also offers actionable insights for policymakers and procuring agencies aiming to design inclusive, innovation-oriented procurement ecosystems. In doing so, the study advances the academic discourse on public procurement and provides practical insights to support a more competitive and resilient European ecosystem by leveraging public procurement volume.

1. Introduction

The rapid advancements in information and communication technologies (ICT) have spurred intense competition among major technology corporations. This race is characterized by the accumulation of intellectual monopolies through proprietary innovations, patents, and extensive data collection, resulting in the formation of highly concentrated tech oligopolies (Rikap and Lundvall, 2021). These powerful entities wield significant influence over the trajectory of technological development, innovation priorities, and market dynamics, often overshadowing smaller players in the industry.
Public procurement emerges as a crucial mechanism to drive innovation and foster a more balanced technological ecosystem in the European Union, accounting for an estimated 14% of its GDP. By strategically guiding

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

public procurement, governments can stimulate competition, promote technological diversity, and counteract the dominance of large tech firms. Public procurement programs that prioritize inclusivity and accessibility can provide startups and small and medium-sized enterprises (SMEs) with the resources, visibility, and opportunities needed to develop and deploy cutting-edge technologies (Commission, 2024). This approach, employed by the European Union among others, not only encourages innovation but also ensures that a broader range of stakeholders can contribute to and benefit from advancements in ICT (Commission, 2024).

In this paper, we focus on the role of public procurement in fostering competition and innovation within the European ICT ecosystem. While previous literature on e-procurement has emphasized digitalization and efficiency gains (Gunasekaran and Ngai, 2008; Vaidya et al., 2006), this technocratic lens often neglects the institutional and strategic complexity of public procurement. In the European context, it is deeply embedded in regulatory frameworks and political objectives, including innovation promotion, SME inclusion, and digital sovereignty (Edler and Georghiou, 2007; Edquist and Zabala-Iturriagagoitia, 2012; Uyarra et al., 2014). This paper adopts the latter perspective, situating public procurement as a policy instrument with transformative potential for the European digital ecosystem. Specifically, we analyze the market share of startups and small companies within the European public procurement landscape, examining their participation rates and success metrics (Niehaves et al., 2024).

Our research questions are as follows: What factors influence the access of startups and small to medium-sized enterprises (SMEs) in the ICT sector to public procurement opportunities at the European level? To what extent do the complexity and administrative burden of public procurement procedures impact the participation of startups and SMEs in European tenders?

This study contributes to the ongoing discourse on strategic public procurement by providing large-scale, empirical insights into how European market structures influence SME and startup participation (Lukkien et al., 2023; Niehaves et al., 2024). While prior research has examined general barriers to SME access, it often focuses on national case studies, lacks cross-sector comparability, or fails to differentiate between startups, micro-, small-, and medium-sized enterprises. By addressing these gaps, the study highlights how procurement design and administrative complexity shape competitive dynamics and outlines opportunities to foster a more dynamic and diversified procurement landscape—supporting the EU's broader goals of innovation, competitiveness, and digital autonomy.

The findings of our study underscore the importance of fostering transparency and accessibility in public procurement processes. Ensuring that smaller companies have equal opportunities to compete for contracts requires addressing structural barriers such as complex application procedures, lack of awareness, and limited organizational capacity. Our analysis reveals significant heterogeneity within the SME category, particularly between startups, microenterprises, and more established small and medium-sized firms, which has important implications for procurement design. One-size-fits-all approaches are insufficient; instead, differentiated and targeted measures are needed to address the specific constraints of distinct SME subgroups. Our research supports and extends the findings of Klassen et al. Klassen et al., 2024 by demonstrating that procurement systems can act as a counterweight to emerging tech oligopolies when designed to empower smaller actors. By conceptualizing SME inclusion as a structural feature of innovation systems, our work contributes to a more nuanced understanding of procurement as a policy instrument. Policymakers should consider targeted interventions, such as procedural simplification, tailored outreach, or quota-based incentives, to strengthen participation and promote inclusive innovation.

2. Theoretical Background and Relevant Work

Public procurement research gains relevance and traction, as scholars and policymakers recognize its potential to foster innovation and support the participation of small and medium-sized enterprises (SMEs)(Commission, 2024). It is important to distinguish between e-procurement and public procurement as two conceptually and practically distinct research strands. While e-procurement focuses on the digitization of procurement processes and the resulting administrative efficiencies (Gunasekaran and Ngai, 2008; Neupane et al., 2012), public procurement research is mainly concerned with the strategic governance of purchasing decisions to achieve broader societal goals (Edler and Georghiou, 2007; Edquist and Zabala-Iturriagagoitia, 2012). These include fostering innovation, addressing market failures, and enhancing digital sovereignty. In this regard, challenges specific to public procurement include complex stakeholder coordination, legal constraints, and multidimensional trade-offs between cost-efficiency, innovation, and inclusivity (Uyarra et al., 2014). A considerable body of work has emerged, focusing on understanding how recent procurement policies and practices can create opportunities for these firms, especially in local and regional markets (Grandia and Meehan, 2017). However, there remains a significant gap in the literature regarding the broader European public procurement landscape, where SMEs are still disadvantaged by aggregation of demand despite accounting for the

majority of European economy. Answering this gap we explore the market share of startups and SMEs in European procurement. In doing so, this paper considers the increasing reliance on big tech companies, a trend that poses potential risks to the EU's critical infrastructure and underscores the need for diversified and inclusive procurement practices to support a coherent and sovereign European innovation ecosystem (Bharosa, 2022; Roberts et al., 2021; Vardanyan and Kocharyan, 2023). Developing a robust understanding of public procurement market dynamics and the impact of procurement frameworks is essential for policymakers and practitioners to meet the strategic goals of public procurement.

2.1. Public Procurement Promoting Innovation

Research on public procurement as a driver of innovation dates back to the 1970s. Early empirical studies explored the relationship between procurement and innovation, concluding that public procurement has a more significant long-term impact on innovation than research and development (R&D) subsidies (Mowery and Rosenberg, 1979; Rothwell, 1984; Geroski, 1990). Their findings highlighted the potential of public procurement to stimulate demand-driven innovation. Despite these early insights, (Edquist and Hommen, 2000) argue that the promotion of innovation through public procurement has even declined in Europe during the 1990s due to the emergence of more stringent competition regulations. These regulations, while aimed at ensuring fairness and efficiency, have inadvertently limited the capacity of public procurement to serve as a catalyst for innovation (Edler and Georghiou, 2007).
More recently, however, the publication of numerous articles on public procurement promoting innovation (PPPI) reflects a renewed and heightened interest in the topic (Georghiou et al., 2014, Amann and Essig, 2015,Chicot and Matt, 2018, Wesseling and Edquist, 2018). Scholars have advocated for a more strategic use of public procurement as a tool to foster demand-driven innovation, emphasizing its potential to mobilize innovation on a large scale. Leveraging the extensive European public procurement landscape and its significant volume has been proposed as a way to stimulate innovation while simultaneously delivering improved services to citizens (Edler and Georghiou, 2007).
These arguments have influenced policy developments, culminating in the inclusion of strategic procurement goals in initiatives such as EU Directive 2014/24/EU or the Interoperable Europe Act (Commission, 2024). This directive explicitly articulates the strategic use of public procurement to promote innovation, marking a significant step toward embedding innovation objectives into procurement practices across Europe (Harland et al., 2021). Despite this progress, significant challenges remain. Amann and Essig, 2015 highlight time consumption and procedural complexity as major obstacles to the successful implementation of PPPI practices in the public sector. Additionally, their findings, aligned with those of Nyiri et al., 2007, reveal that modern public procurement often incorporates multiple objectives, such as cost savings, environmental sustainability, and social responsibility. These diverse goals are not always easily reconciled, as they frequently entail trade-offs. For example, prioritizing cost efficiency may conflict with the higher costs associated with procuring innovative products and services. Uyarra et al., 2014 conducted a supply-side survey identifying that lack of demand for innovation and lack of interaction with the procuring organisations are due to reduced contract sizes in pursuit of minimising transaction costs.
The type of procurement procedure employed plays a critical role in shaping innovative outcomes and SME access. According to Soliño and de Santos, 2010, the negotiated procedure is particularly conducive to innovation, as it facilitates a more detailed formulation and discussion of specifications and requirements. However, this approach entails higher time and resource expenditures compared to an open procurement process. The findings of Soliño and de Santos, 2010 are consistent with those of Uyarra et al., 2014, further supporting the notion that procurement design significantly influences innovation potential and multiple objectives may result in strategic dilemmas. This growing body of research underscores the need for a more strategic and nuanced approach to public procurement, one that balances competing objectives while leveraging its potential as a driver of innovation.

2.2. Roles of Startups in Innovation

Startups gain an increasing role as drivers of technological innovation (Bharosa, 2022; Niehaves et al., 2024). Innovation is understood here not only as technological novelty, but as the ability to generate, apply, and scale contextually relevant solutions that create systemic value across public and private sectors. This broad understanding aligns with Isenberg's concept of entrepreneurial ecosystems, where startups serve as dynamic agents of change embedded in interdependent networks of institutions, markets, and policy frameworks (Isenberg, 2010). In this view, fostering startup participation in public procurement contributes to innovation not merely by introducing new products, but by reshaping the structure of the innovation system itself.

This is particularly evident in the information technology field and public sector, where startups develop solutions that not only address specific market needs but also spur organizational digital transformation (Lukkien et al., 2023). By offering tools and platforms, startups empower public organizations to modernize their operations and enhance service delivery for their clients (Bauer, 2025). In the public sector, these innovations can lead to significant improvements in how public administrations interact with citizens and manage public resources (Bharosa and Janowski, 2024; Niehaves et al., 2024). However, the remaining and increasing dominance of BigTech companies (Jácome de Moura et al., 2024) introduces significant challenges for fostering innovation ecosystems, especially in Europe (Lukkien et al., 2023). In the context of this study, we define "Big Tech companies" as large multinational technology firms that exert disproportionate influence over digital infrastructure, data ecosystems, and innovation agendas, often through control of platforms, standards, and intellectual property rights. Their market power is reinforced by economies of scale, network effects, and high entry barriers for smaller actors (Rikap and Lundvall, 2021; Gleiss et al., 2023). This dependency exacerbates concerns regarding Europe's digital sovereignty, as reliance on non-European providers can expose vulnerabilities in terms of data control, security, and strategic autonomy (Rikap et al., 2024). Addressing such issues requires a response that aligns innovation policy with the principles of sovereignty and competitiveness, as becoming visible through the European Commissions endeavors like the AI and Interoperable Europe Act (Commission, 2024; Commission, 2022).
In the context of the European single market, public procurement holds the potential to bridge gaps for startups, enabling them to overcome barriers to entry and scale (Niehaves et al., 2024). However, these mechanisms are not without limitations. Market barriers, including cross-border challenges and preferential procurement practices, restrict the effective deployment of innovative solutions (Niehaves et al., 2024). By addressing market barriers and promoting a more inclusive approach to procurement, policymakers could significantly enhance the innovation landscape (Nose, 2023; Edquist and Zabala-Iturriagagoitia, 2012).
The participation of SMEs and startups in public procurement is not only a matter of economic inclusion but also of systemic innovation capacity. Building on the concept of National Innovation Systems (Lundvall, 1992), these firms act as vital carriers of knowledge diversity, experimentation, and adaptive innovation. Unlike large incumbents, startups often deliver context-specific, non-standardized solutions that challenge established technological trajectories and governance models. However, this lack of standardization introduces complexities for public buyers, who are often required to conform to strict procedural rules, risk-averse contracting standards, and interoperability constraints. As a result, the very heterogeneity that makes startups valuable for dynamic innovation ecosystems can conflict with procurement regimes optimized for stability and scale. Addressing this tension requires procurement frameworks that accommodate exploratory and learning-oriented interactions between public buyers and smaller, innovative suppliers (Uyarra et al., 2014).

2.3. SME Participation in Public Procurement

SME participation in the European procurement landscape has long been a focal point of interest. The European Commission has consistently addressed challenges and opportunities related to SMEs in public procurement, as reflected in numerous initiatives and policy documents (Commission, 1990; Commission, 2022; Commission, 2024). Recognizing the critical role of SMEs in driving innovation and economic growth, these efforts have sought to create a more inclusive and accessible procurement environment.
The barriers that impede SMEs from fully participating in the European procurement market were systematically examined by a recent study of the OECD, 2018. Their report on practices and strategies for shared benefits of SMEs in public procurement identified structural and procedural obstacles, such as complex administrative requirements, high tendering costs, and a preference for larger contracts, which collectively hinder SMEs' ability to compete effectively. These findings underline the persistent challenges that remain despite policy interventions aimed at enhancing SME access. To address these challenges, the European Commission introduced Directive 2014/24/EU, explicitly targeting SME inclusion in the procurement process. Among its key measures was the encouragement to divide contracts into smaller, more accessible lots, thereby reducing contract sizes to increase SME participation and improve their success rates. While this approach initially appeared promising, empirical studies have presented mixed results regarding its effectiveness (Glas and Eßig, 2018; Hoekman and Taş, 2022). Simply dividing tender contracts into smaller lots is insufficient to transform the European public procurement market into an innovative ecosystem Timmermans and Zabala-Iturriagagoitia, 2013. Successfully fostering startup and SME access while promoting innovation, requires a strategic and holistic approach (Timmermans and Zabala-Iturriagagoitia, 2013).
A related critique comes from Flynn et al., 2015, who examined disparities in tendering capabilities among SMEs, which are often mistakenly perceived as a homogeneous group. He highlighted that the current "one-size-fits-all" policy approaches fail to account for the vast differences between e.g. micro-enterprises and

medium-sized companies, all of which are collectively categorized under the term SMEs. By attempting to address the needs of such diverse entities simultaneously, these policies introduce additional complexity into procurement processes, frustrating public buyers and thereby further limiting the intended benefits for SMEs. Beyond the discussion on tender lot sizes, Directive 2014/24/EU also addressed procurement aggregation strategies in Articles 37 to 39. Aggregation techniques such as central purchasing bodies, framework agreements, and electronic catalogs were promoted as tools to enhance efficiency and achieve economic and administrative benefits. However, many researchers, including Sanchez Graells and Herrera Anchustegui, 2014 and Albano et al., 2010, have raised concerns about the potential negative consequences of these strategies. They caution that aggregated and centralized demand may lead to market concentration, suppressing SMEs and, over time, fostering oligopolistic competition that could undermine innovation and market diversity. Oligopolistic dependencies not only undermine the intended economic benefits of aggregation strategies but can also have adverse effects on digital sovereignty in areas such as critical infrastructure within Europe. Initial empirical evidence supporting these concerns has been found in the national Spanish procurement market (Arosa et al., 2025).
Building on these insights, this paper aims to investigate the factors influencing startup and SME access to public procurement at the European level, with a focus on the ICT sector. By addressing this gap, the study seeks to offer valuable insights into the challenges and opportunities for public authorities and decision-makers leveraging PPPI and promoting SME participation in the increasingly centralized and competitive procurement market. Additionally, the paper provides a robust methodology for utilizing the open government data platform, Tenders Electronic Daily (TED).

3. Data and Methodology

An exploratory quantitative methodology was adopted for this study to effectively answer the research question. The choice of this method aligns with the characteristics of the European procurement landscape, where a substantial volume of contract and award notices is published daily. The identification of data sources was grounded in a thorough review of the literature.

3.1. Data Sources

Building on the identified data sources from the literature review, the database for our analysis was compiled from three major sources: the procurement platform Tenders Electronic Daily (TED) 'European Union', n.d. firm-level data from the commercial database Orbis Moodyś, n.d. and the UN Treasury, which provided historical exchange rates 'United Nations', n.d.
TED is the official EU portal for high-value public procurement and mandated under Directives 2014/24/EU and 2014/25/EU. Its legal authority and accessibility make it highly suitable for analyzing procurement patterns relevant to EU innovation and digital sovereignty goals. In addition, TED offers rich metadata including procedure types, contract values, and buyer identities, enabling detailed structural analysis across sectors.
Firm-level data was sourced from Orbis due to its harmonized classification of SMEs and startups across countries, based on standardized financial and operational thresholds. Alternative sources such as national registers lack this consistency. Orbis also enables historical tracking and reliable firm identification via e.g. standardized company IDs, supporting clean integration with TED data.
This multi-source approach ensures policy relevance, analytical depth, and robust cross-country comparability for studying SME and startup participation in European ICT procurement.

3.2. Data acquisition

Building on the data sources introduced earlier, the process of data acquisition and preparation focused on collecting TED, Orbis, and UN Treasury data to construct a comprehensive and analyzable database. TED data served as the foundational source, providing detailed public procurement notices. Specific attention was given to extracting the winner field from the TED JSON documents, which included identifiers for successful bidders. These identifiers were mapped to individual countries using three-letter ISO country codes. However, a subset of entries with non-standard codes (e.g., "1A0") could not be mapped and was excluded from the analysis. To enable firm-level classification and enhance the granularity of the dataset, Orbis data played a pivotal role.

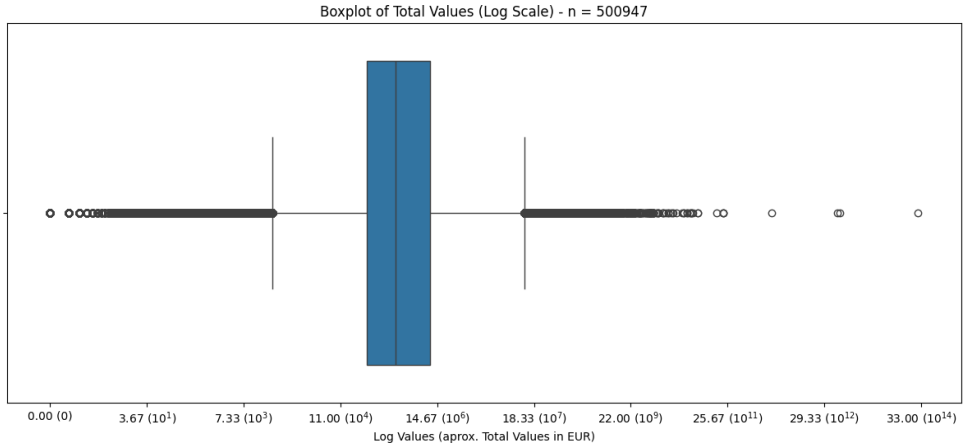

Fig. 1 – Boxplot of Total Values per Tender (Log Scale).

Orbis provided essential corporate information, which was crucial for categorizing entities, such as startups and SMEs, based on their size, operational scope and date of incorporation. Since country-specific identifier formats, such as VAT numbers, tax numbers, and commercial register entries, varied significantly, a systematic multi-step matching process was implemented. Identifiers were first queried within the most likely category for each country, and unmatched entries were subsequently searched in alternative categories. While this approach maximized the match rate, countries with insufficient Orbis coverage or unmappable identifiers were excluded from the final analysis.
The integration of TED and Orbis data required a robust storage and processing infrastructure. While TED data was initially stored in MongoDB for flexibility during processing, key fields were imported into a PostgreSQL relational database. PostgreSQL's capability to query JSON and array structures allowed for seamless integration of TED and Orbis data. Additionally, the database adhered to the first normal form by normalizing company identifiers into a separate table, ensuring efficient and atomic storage of values.
The fully integrated database enabled efficient querying and analysis through SQL operations, joins, and aggregations. By aligning tender data, company classifications derived from Orbis, and financial metrics, the study was equipped to investigate tender outcomes, market shares and influencing dynamics of public procurement across the European Union and various branches of industry.

3.3. Data Exploration and Preprocessing

After collecting the data, we conducted an initial analysis of the distribution across various variables. Our primary focus was on the tender value, as this variable is often strongly correlated with the size of the winning company, as discussed in Section 2.3. During this exploration, we identified significant anomalies in the total value variable, such as a large proportion of contract values equaling 0, as well as tender lots valued at 1 billion euros, published by, e.g. a local Austrian municipality. These anomalies suggested an extreme value distribution, prompting us to apply a log transformation to improve the data's interpretability and mitigate the influence of outliers. A boxplot was created to visualize the adjusted data and identify outliers (see Fig. 1). The interquartile range (IQR) was calculated to determine the boundaries for typical values, with the lower whisker extending to €4,544.04 and the upper whisker to €63,379,652 in the transformed dataset. Values falling below or exceeding these thresholds were classified as outliers.

3.4. Dataset

The initial dataset retrieved for this study comprised 1.7 million contract and award notices from the open government data platform TED, of which 939,165 unique contracts were identified. These unique records serve as the foundation for the subsequent analysis, providing a reliable and well-structured dataset for investigating public procurement dynamics across the European Union. Building on the data exploration and preprocessing steps outlined in the previous section, table 1 provides a detailed summary of the refined database. This overview highlights the key outcomes of the cleaning process and outlines the structure of the dataset as utilized in the following analyses.

TED Dataset	
Retrieved notices	1,642,250
Unique notices	939,165
Unique notices with CPV-Code classification	771,016
Unique notices with winner information	259,487
Retrieved winners	496,445
Unique winners	209,464
Unique notices with information on tender value (> 0)	491,073
Unique notices with information on tender value (> 4,544. < 63,379,652)	461,043
Unique notices with defined buyer country	858,822
Unique notices with defined winner country	259,487

Tab. 1 – Summary of the TED Dataset Used for Our Analysis

To address our research question, we employed a classification system to identify startups and SMEs within the dataset, leveraging the firm-level data provided by the Orbis database. Startups were defined as small companies with no branches and a founding date after January 1, 2015. This definition allowed us to identify 18,191 winner companies in our combined dataset that met these criteria.
The Orbis database categorizes companies by size based on financial and operational metrics. Very large companies (VL) are those that meet at least one of the following thresholds: operating revenue of ≥ 100 million EUR, total assets of ≥ 200 million EUR, a workforce of ≥ 1,000 employees, or listing on a stock exchange, provided their revenue or asset-per-employee ratios are not disproportionately low. Additionally, companies with unknown financial metrics but capital exceeding 5 million EUR are also classified as very large. Large companies (L), on the other hand, meet at least one of these criteria: operating revenue of ≥ 10 million EUR, total assets of ≥ 20 million EUR, or a workforce of ≥ 150 employees, while also maintaining reasonable revenue or asset-per-employee ratios. Companies with unknown revenue, assets, or employee counts but capital between 500,000 EUR and 5 million EUR fall into this category.
Medium-sized companies (M) are identified as those that meet at least one of the following conditions: operating revenue of ≥ 1 million EUR, total assets of ≥ 2 million EUR, or a workforce of ≥ 15 employees, but do not qualify as large or very large companies. All companies that fail to meet the criteria for these categories are classified as small companies (S).
This classification system was crucial in systematically identifying startups and SMEs within the dataset, ensuring alignment with the study's objectives.

4. Results

In order to address our research question, we conducted an extensive analysis of our database, focusing on variables that influence market dynamics, with particular emphasis on the access of SMEs and startups in the ICT sector. We aim to uncover key factors that shape the competitive landscape and provide insights into the challenges and opportunities faced by smaller firms within public procurement processes. Relevant variables considered in this analysis include sectoral distribution, measured through the European Common Procurement Vocabulary (CPV codes), and European procurement procedure types. Additionally, the procedure types provided valuable context regarding how procurement practices influence participation and success of SMEs. By analyzing these variables, we gain a deeper understanding of the barriers that startups and SMEs face in accessing the European public procurement market for ICT.

4.1. SME Access in European Public Procurement for ICT

We focused on CPV codes we assume to be relevant to ICT industries, selecting the following divisions: 48: 'Software packages and information systems'; 72: 'IT services: consulting, software development, Internet, and support'; 30: 'Office machinery, equipment, and supplies'; 32: 'Radio, television, and communication equipment'; 50: 'Repair and maintenance services'. Filtering tenders by these CPV-Divisions yielded 24,277 unique tenders and 34,287 tender lots. These lots were awarded to 15,346 distinct companies, categorized based on Orbis classifications. For a complete display of the distribution see Table 2. The sum of tenders is higher than 24,277 as multiple companies can participate in a tender.

	Unique Companies	Lots Won	Tenders Participated in
Small Companies	3,465	5,744	4,638
Medium Companies	5,954	11,695	9,246
Large Companies	3,331	10,461	8,647
Very Large Companies	1,497	6,387	5,529

Tab. 2 – Distribution of Companies in Public Procurement for ICT

Figure 2 illustrates the values presented in 2 and makes the comparison between the distribution of company sizes in the ICT procurement landscape and their success rates. Small companies are disproportionately disadvantaged, with their share of lots won (16.75%) being significantly below their respective presence (24.32%) in the ICT procurement market. In contrast, large and very large companies outperform expectations. Large companies, representing 23.38% of the landscape, secure 30.51% of the lots. Very large companies exhibit the most pronounced overperformance, winning 18.63% of the lots while constituting just 10.51% of companies engaging in ICT tenders.

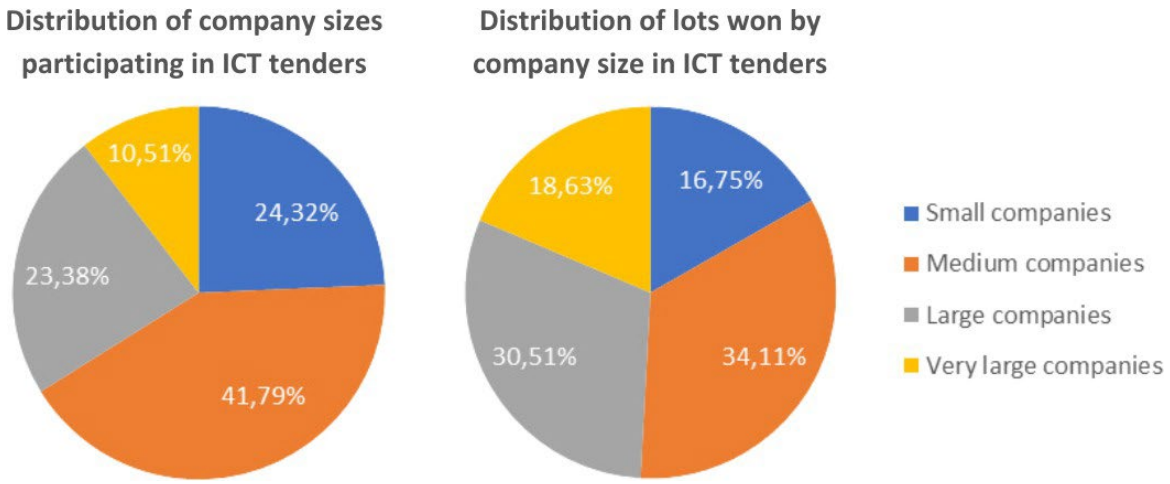

Fig. 2 – Distribution of Company Sizes in Public Procurement for ICT.

Based on our initial observations, we analyzed the values per tender lot to gain deeper insights into the patterns and the accessibility of of the ICT procurement landscape in respect to company sizes. A descriptive summary of all results can be found in Table 3. We analyzed all tenders in our database, as well as ICT-specific tenders, to gain insights into the unique characteristics of the ICT sector. We conducted our analysis both unfiltered (contract value > 0) and filtered, using the predefined value range introduced in Section 3.4 to exclude abnormal outliers. It is important to note that contract values may appear multiple times in this analysis. When multiple companies are listed as winners, the corresponding contract value is attributed to each company, as the quality of the data extracted from TED did not allow for proportional allocation.

Small companies win only 16.2% of ICT tender lots and 17.2% of the total procurement value, far lower than their share in overall public procurement, where they account for 37.5% of lots and 38.9% of value. On the other hand, medium-sized companies perform relatively well in ICT procurement, capturing 32.6% of ICT tender lots and 31.1% of the total value, much higher than their share in the general public procurement sector, where they only account for 5.9% of lots and 5.8% of contract value. The contrast between small and medium companies in ICT is striking — medium-sized companies have nearly double the share of ICT procurement in both lots and value, which is the opposite of the general public procurement sector, where small companies have a higher share. This suggests that procurement practices and market characteristics of the ICT sector, with its demand for specialized skills and larger project scopes, tend to favor medium-sized companies over small ones.
Additionally, filtering the data reveals that outliers significantly distort the unfiltered data, particularly in the general procurement sector, where the presence of large, extreme values inflates the overall figures. Filtering

Company classification	Avg value	Total value	Tender count
Small	5,382,428.71	504,660,807,387.35	93,751
Medium	6,303,362.00	921,866,693,037.66	146,250
Large	8,408,545.19	104,428,452,369.87	124,193
Very large	11,067,923.32	988,343,416,295.43	89,298
Small (filtered)	2,472,323.29	213,505,671,951.45	86,358
Medium (filtered)	2,365,978.21	32,060,049,531.27	13,540
Large (filtered)	2,775,745.37	321,475,725,687.79	115,816
Very large (filtered)	3,370,755.36	27,689,069,468.58	82,145
Small companies in ICT	5,432,224.01	54,313,175,671.39	9,998
Medium sized companies in ICT	3,208,348.39	63,775,549,325.60	19,878
Large companies in ICT	6,994,184.93	128,315,316,733.52	18,346
Very large companies in ICT	15,928,020.16	171,783,679,466.77	10,785
Small companies in ICT (filtered)	2,230,218.78	20,397,580,921.04	9,146
Medium sized companies in ICT (filtered)	1,996,922.82	36,879,170,666.26	18,468
Large companies in ICT (filtered)	2,493,002.64	43,190,001,643.78	17,292
Very large companies in ICT (filtered)	3,654,161.85	35,434,407,496.17	9,697

Tab. 3 – Count and Tender Value per Company classification

out extreme outliers significantly reduces the total procurement sums in both sectors. However, the effect is more pronounced in the general sector. Once these outliers are removed, the values in the ICT sector remain consistently higher, emphasizing the unique characteristics and importance of ICT procurement in Europe.

4.2. Procurement procedures

As highlighted in Section 2.1, procedure types are considered to exert a direct influence on SME access in public procurement (Soliño and de Santos, 2010) Procurement procedures not only determine the accessibility of tenders for different company sizes but also influence the alignment of procurement goals, ranging from cost efficiency to fostering innovation. Drawn from our extensive literature review, we sought to examine the different types of procurement procedures within the subset of ICT procurement data (CPV Divisions 48, 72, 30, 32, and 50). Our analysis identified a total of 24,277 unique tenders within this subset, offering a comprehensive view of the distribution of procedure types and the participation of various company sizes. A summary of this distribution can be found in Table 4, highlighting the dominance of Open Procedures (71.91%), followed by negotiated procedures without call (10.49%) and restricted procurement tenders (8.25%).

Procedure Type	Count Tenders	Small Companies	Medium Companies	Large Companies	Very Large Companies
Open	1,745,8	3,554	6,821	6,124	3,925
Negotiated without Call	2,546	308	749	845	698
Restricted	2,004	396	868	743	378
Negotiated with Call	1,207	169	438	455	312
Other Single	900	184	311	409	164
Not Defined	54	13	28	28	18
Competitive Dialogue	48	7	17	15	16
Other Multiple	33	5	8	15	8
Competitive Tendering	27	2	6	13	10

Tab. 4 – Procurement Procedures and SME Access in Public Procurement for ICT

As anticipated, small companies are most frequently represented in Open Procedures. In contrast, small companies are notably underrepresented in more complex, resource-demanding processes such as Negotiated Procedures and Competitive Dialogue. Medium-sized companies, on the other hand, exhibit a more balanced distribution across various procedure types. They are particularly well-represented in Negotiated Procedures without call and Restricted Procedures. Large and very large companies, with their substantial resources, predominantly participate in Negotiated and Restricted Procedures. Very large companies, in particular, tend to dominate procedures like Competitive Dialogue and Negotiated Procedures with Call, which are typically used for high-value, resource-intensive projects. While their involvement in Open Procedures is relatively limited, both large and very large firms maintain a presence.

Building on the previous analysis of participation patterns across different procurement procedures, we now extend our focus to the contract values and earnings within these procedure types. This offers a more complete understanding of how market access and procedural complexity affect not only the number of tenders small, medium, large, and very large companies participate in, but also the financial returns they achieve. By analyzing the distribution of total contract values within these procedures and the average contract values won by each company classification, we provide insights into how different procurement procedures impact the financial performance of companies of varying sizes and can provide further insights on factors influencing SME access in ICT procurement.

For small companies, despite their significant participation in Open Procedures — comprising 93% of their engagement in tender lots — they win only a modest share of the total contract value. In fact, their total contract value in Open Procedures amounts to approximately €13.67 billion, with an average contract value of €4.18 million, as shown in Table 6. In procedures like Negotiated with Call for Tenders, small companies capture only a small proportion of the total contract value, with an average contract value of approximately €5.93 million in this category. In contrast, medium-sized companies exhibit a more balanced participation profile across various procedures. They are notably active in Open, Negotiated without Call, and Restricted Procedures, with a significant share of their tenders being awarded through Restricted Procedures (25%) and Negotiated Procedures without Call (30%). As shown in Table 7, the average contract value for medium-sized companies in Open Procedures is approximately €1.62 million. However, their presence in more complex tenders, such as Restricted and Negotiated Procedures, allows them to secure larger contracts, with average values reaching €2.64 million in Restricted Procedures and €3.78 million in Negotiated Procedures with Call. As a result, medium-sized companies capture a more substantial share of the total value. In fact, medium-sized companies account for approximately 42.1% (Restricted) and 20.4% (Negotiated with Call), overperforming in respect to their market presence.

Large companies dominate the Negotiated and Restricted Procedures, where high-value contracts are often awarded. As illustrated in Table 8, in Restricted Procedures, the average contract value for large companies is approximately €3.85 million, while in Negotiated Procedures with Call, it rises to over €6.91 million. These firms are particularly well-suited to handle large-scale and complex IT projects, and as a result, they consistently capture a significant share of the total contract value.Large companies win 50.6% of the total value procured via Restriced procedure and 56.3% of competitive tender procedures.

Very large companies are the primary participants in the most complex and high-value tenders, such as Competitive Dialogue and Negotiated Procedures with Call. As seen in Table 9, the average contract value for very large companies in Negotiated Procedures with Call exceeds €17.48 million, while in Competitive Dialogue, the average contract value is even higher, at €34.57 million. As a result, very large companies capture the lion's share of total contract values, accounting for approximately €62,520 billion and 48.7% of the total procurement value in the overall ICT sector.

5. Discussion

Our analysis of European public procurement in the ICT sector highlights a distinct advantage for large and very large firms in securing tenders. While medium-sized companies form the majority of participants, their share of lots won is lower than expected. Small companies, in particular, are disproportionately disadvantaged, capturing significantly fewer tender lots and lower total contract values relative to their overall presence.

These findings align with prior literature emphasizing the barriers SMEs face in public procurement, including resource limitations, stringent procedural requirements, and economies of scale favoring larger firms (Soliño and de Santos, 2010). The procurement landscape for ICT reflects these structural challenges, with larger firms leveraging their financial and technical capacity to secure high-value contracts. Small firms, by contrast, are more reliant on Open Procedures, which offer lower entry barriers but tend to result in smaller contract values.

The contrast between small and medium-sized enterprises (SMEs) is particularly notable. While small companies struggle with access, medium-sized firms perform relatively well in ICT procurement compared to general public procurement. This suggests that ICT procurement favors firms with a moderate level of specialization and resources, a finding that supports the argument that a "one-size-fits-all" SME policy approach may not be suitable (Soliño and de Santos, 2010). Instead, differentiated policies are needed to support smaller firms without undermining the competitiveness of medium enterprises.

The impact of procurement procedures on firm participation further reinforces these observations. Small companies are most active in Open Procedures, whereas larger firms dominate more complex processes such as Negotiated and Competitive Dialogue tenders. These procedures often involve resource-intensive require-

ments, making them less accessible to smaller firms. Medium-sized enterprises demonstrate a balanced distribution across procedure types, suggesting that they have the capacity to navigate moderately complex procurement processes. These results emphasize the need to differentiate procurement procedures not only by legal form but also by their de facto complexity and resource demands. Smaller firms often lack the legal expertise, internal capacity, or financial flexibility to engage with complex procedures such as restricted or negotiated tenders. This indicates that administrative burden acts as a structural barrier, reinforcing asymmetries in participation and limiting the intended strategic effect of public procurement; a central concern addressed in our second research question.

Moreover, filtering out extreme contract values (outliers) significantly alters the observed distribution in general procurement. However, in the ICT sector, even after applying our filter, large firms continue to hold a dominant share of awarded contracts. This indicates that ICT tenders, by nature, involve high-value contracts that favor companies with substantial financial and operational capacity. The limited impact of filtering on the ICT sector suggests strong data quality and highlights the sector's economic and societal relevance.

From a theoretical perspective, this study contributes to the growing literature on public procurement as an instrument of innovation policy by offering large-scale empirical evidence on structural asymmetries in startup and SME access. Building on and extending previous work by Edler and Georghiou (2007) and Uyarra et al. (2014), it highlights how procurement design, rather than being neutral, actively shapes competitive dynamics in digital markets. By conceptualizing startup participation as a systemic innovation function, our analysis aligns with the National Innovation Systems framework Lundvall, 1992, illustrating how the inclusion or exclusion of smaller actors affects the adaptive capacity of public sector innovation. Furthermore, the integration of procurement, firm-level, and financial data offers a replicable methodological approach for studying innovation ecosystems from a structural perspective. In sum, the study advances theoretical understanding of how procurement processes interact with broader institutional and market structures.

6. Limitations and Further Research

This study analyzed 14 months of European procurement data, providing valuable insights into the state of public procurement datasets as well as startup and SME participation in the European public procurement landsace. The relatively short timeframe covered may limit the ability to generalize the results. Longer-term studies will be necessary to confirm whether the observed trends and patterns in procurement practices and participation are stable over time. The use of exploratory data analysis (EDA) and descriptive statistics, while effective for uncovering patterns, also introduced certain limitations. These include the potential for subjectivity, scalability challenges when handling larger datasets, and the possibility of overfitting or selectively highlighting patterns. The study did not employ more advanced statistical techniques, such as regression analysis or machine learning, due to the poor quality of the underlying data. This restriction limited the ability to explore deeper correlations or causations. Future research should address these limitations by extending the analysis period and employing advanced methodologies to derive more nuanced and robust insights.

In Europe, initiatives such as GovTech Connect and GovTech Lab have been established to tackle the challenges addressed in this paper and explore potential solutions (PUBLIC. et al., n.d. 'Innovation Agency Lithuania', n.d.). However, no significant impact on improving access for startups and SMEs has been observed thus far. Further investigation is required to assess whether these initiatives can effectively enhance long-term participation and lower existing barriers in public procurement.

As data quality continues to improve, the application of advanced statistical techniques could uncover critical trends, inefficiencies, and causal relationships. This, in turn, would enhance the reliability of procurement data, supporting data-driven policymaking and enabling more targeted, evidence-based interventions. By leveraging these insights, policymakers can optimize the allocation of public procurement funds, ensuring that well-defined and informed strategies maximize the economic impact of European procurement initiatives.

7. Conclusions

Our study underscores the structural challenges small firms face in European ICT public procurement. While medium-sized firms perform relatively well, small companies remain underrepresented in awarded tenders and contract values. Larger firms, particularly very large ones, dominate high-value contracts and complex procedures, reinforcing existing market advantages and dependencies.

These findings suggest that policy interventions should be tailored to address the specific challenges of small firms while ensuring a competitive environment for medium-sized enterprises. Reforms in procurement processes, such as lowering barriers in complex procedures or providing targeted support mechanisms, could

enhance SME participation without compromising efficiency and competition and thereby leveraging procurement volume for strategic objectives like an innovative European ecosystem and digital autonomy.

Abstract. This study investigates the potential role of diversity in shaping innovation outcomes within the GovTech sector, an emerging domain where startups collaborate with public administrations to drive digital transformation. While GovTech is positioned as a vehicle for more agile, inclusive, and citizen-oriented public services, its effectiveness hinges on the extent to which it mirrors the populations it serves. Grounded in theories of diversity management and diffusion of innovation, this research explores how the demographic composition of GovTech founders compares to public administration employees, the broader startup ecosystem, and the general citizenry in Germany. The study employs a mixed-methods approach, combining 108 expert interviews with GovTech founders and comparative analysis using secondary data from national datasets. It focuses on three diversity dimensions: gender, migration background, and socio-economic (labor vs. academic) background. The findings reveal substantial misalignments. GovTech startups are heavily male-dominated (85.7% male founders), starkly contrasting with the higher female representation in public administration (58.6%) and the near gender parity in the citizenry. Migration background is also underrepresented among GovTech founders (22.7%) relative to citizens (28.6%), though aligned with general startup trends. GovTech shows relatively strong socio-economic inclusivity, with 62.8% of founders from labor backgrounds, exceeding both startup and citizen benchmarks. These demographic mismatches raise concerns about the representational legitimacy and inclusiveness of GovTech solutions, which may limit their relevance, adoption, and impact. Public administrations, while more gender-diverse, also exhibit gaps, particularly in migration and socio-economic representation, potentially compounding the disconnect between technology providers and end-users. The study proposes strategic responses, including inclusive procurement policies, support for diverse founders, and cross-sector alignment initiatives to strengthen equity in digital public services.

Keywords. GovTech, government technology, diversity management, public sector innovation.

1. Introduction

The intersection of diversity and digital innovation in the public sector has garnered significant attention, as public administrations strive to deliver equitable, citizen-centric services through technological transformation (Chandler, 1984; Nose, 2023). In this context, GovTech — an emerging technology market at the crossroads of government and technology — has emerged as a relevant supplier for public sector innovation (Bharosa, 2022; Niehaves and Klassen, 2024). Through partnerships between public administrations and startups, GovTech promises to overcome traditional bureaucratic constraints and foster solutions that are more inclusive and reflective of diverse citizen needs (Niehaves and Klassen, 2024).

Nevertheless, a new avenue to procure solutions, does not necessitate a higher degree of diversity. It has long been recognized that public administrations actions are biased through culture, socialization and bureaucratic structures (Battaglio et al., 2019). Such biases may foster prejudice, which can negatively affect how individuals evaluate and interact with others, potentially leading to unequal treatment or exclusion (Wyszynski, 2020). Research in the last few years depicts a similar trend in the results of technologies, specially those used as decision support systems in public organizations (Buolamwini, 2018; O'Connor and Liu, 2024). As such, both solutions and the organizational makeup of solution providers are becoming more central in shaping digital services for citizens (Bauer, 2025).

Despite the providers of GovTech solutions, GovTechs, being attributed high potential and a clear value proposition (Bharosa, 2022), a gap exists in research on how diversity within GovTech compares to other relevant groups, such as the broader startup ecosystem, public administration personnel, and the citizenry their solutions aim to serve. Without this understanding, it remains unclear whether GovTech can fulfill the promise of fostering equity and inclusion or rather simply replicates existing disparities (Bharosa, 2022). This study addresses such gap by posing the research questions:

RQ: How do diversity measure in GovTech boards compare to their clients and service recipients? Which effects on representation and bias does this entail?

To answer the question, we draw on the theoretical lenses of diversity management and diffusion of innovation theory (McNutt et al., 2016; Sabharwal et al., 2018). Diversity management highlights the organizational benefits of inclusive team compositions, while diffusion of innovation theory emphasizes the importance of alignment between stakeholders for successful technology adoption. Together, these perspectives provide a robust foundation for analyzing diversity's role in shaping GovTech's impact.

Previous research in diversity management and public sector innovation (vom Brocke et al., 2009, 2015) suggest three attributes of diversity as most pertinent for further investigation: 1. *gender*, 2. *migration backgrounds*, and 3. *working-class/labor backgrounds* (Chen, 2014; Gross-Gołacka et al., 2022; McGrandle, 2017). Thus, our research involves collecting and analyzing data on these diversity dimensions from GovTech startups, general startups, public administration employees, and citizens. The findings reveal notable alignments and misalignments. GovTech startups closely mirror the broader startup ecosystem but diverge significantly from the demographics of their public administration clients and citizen end-users. These discrepancies show opportunities for innovation and areas where improved representation could enhance trust, alignment, and inclusivity.

This study contributes to the emerging discourse on GovTech and public sector innovation by offering a data-driven assessment of diversity across relevant groups. By identifying gaps and proposing pathways for addressing them, we provide insights for policymakers, GovTech startups, and public administrations seeking to foster equity and inclusion in the digital age. Additionally, we outline future research directions to deepen understanding and extend the applicability of our findings, including the exploration of international contexts and the use of focus groups to further evaluate diversity's role in GovTech's evolution.

2. Conceptual and Theoretical Background

2.1. Diversity in the Public Sector

Public administrations serve as the extended arm of political institutions, tasked with representing and safeguarding the interests of citizens. This role becomes especially significant in the design and implementation of

digital infrastructure that provides critical governmental services to often under-served populations (Bharosa and Janowski, 2024; Desai and Manoharan, 2024). Inclusive and equitable infrastructures are essential to reduce the digital divide and ensure that all citizens, in particular those from marginalized communities, have access to critical digital public services (Denhardt and Denhardt, 2015). For this, representation plays a central role in safeguarding citizen interests by ensuring diverse perspectives are embedded in the development and governance of such systems (Chandler, 1984).

Diversity management has been widely shown to have a significant positive impact on the performance of teams and organizations, enhancing creativity, problem-solving, and decision-making quality (Bassett-Jones, 2005). However, research on diversity in general often times lacks carryover, as public institutions represent a specific case due to their highly structured and hierarchical nature (Choi and Rainey, 2010; Sabharwal et al., 2014). While these structures enable standardization and accountability, they also limit the adaptability needed to effectively integrate components of diversity into decision-making processes (Oppong, 2013). Furthermore, public administrations are increasingly expected to adhere to international frameworks, such as the *United Nations Global Compact on Diversity, Equity, and Inclusion* or the *Charta of Diversity*, which emphasize the importance of embedding these values into organizational practices and culture.

Despite aspirations, public administrations often struggle to realize diversity, equity, and inclusion goals not only externally through politically created policy, but also internally. Issues such as under representation of minority groups, limited avenues for inclusive participation, and the bureaucratic inertia inherent in many public institutions present persistent challenges (Sabharwal et al., 2018). These struggles can undermine their ability to act as representatives of diverse citizen interests, particularly in the context of rapidly evolving digital governance demands (McNutt et al., 2016). Addressing these challenges requires not only systemic reforms to improve representation within public institutions but also a commitment to incorporating diverse stakeholder input into the design and operation of digital public infrastructure, a process that becomes even more pressing in the face of an overaging populus of public servants and a lack of aspiring junior staff (Desai and Manoharan, 2024).

2.2. Diversity in Diffusion of Innovation

Diversity within public administrations is not only critical for equitable representation, but may also serve as a driver of innovation and success (Desai and Manoharan, 2024). The integration of diverse perspectives fosters creative problem solving (Bassett-Jones, 2005) and enables public institutions to design digital public infrastructures that are more inclusive and aligned with the needs of all citizens. This becomes even more relevant in times of growing biases visible through solutions deployed (O'Connor and Liu, 2024). The need for such diversity-driven approach is particularly relevant in the context of the diffusion of innovation, where the acceptance and adoption of new technologies are influenced by the alignment between stakeholders (Tseng et al., 2024).

Isomorphism, a concept from institutional theory, highlights the tendency of organizations to become similar over time, driven by normative, mimetic, and coercive pressures (DiMaggio and Powell, 1983). This similarity fosters positive business relationships by reducing uncertainty, increasing trust, and facilitating collaboration (Bartoli and Rouet, 2023; Bauer, 2025; Li and Chung, 2020). Previous research on GovTech has found indicators, that startups conform in their organizational makeup to better represent public administration officials wishes (Bauer, 2025). In theory, when public administrations share commonalities with the citizenry they serve and the technology providers they engage with, the likelihood of successful relationship development and innovation diffusion increases (Frumkin and Galaskiewicz, 2004; Lodge and Wegrich, 2005). For instance, public institutions that reflect the diversity of their citizens are better positioned to understand and address their unique needs, thereby enhancing the acceptance of new technologies and services.

The principle of similarity creating higher acceptance underscores the importance of diversity as a strategic asset in public administrations (Li and Chung, 2020). By mirroring the diversity of the populations they represent and fostering alignment with technology solution providers, public institutions can build stronger relationships and facilitate smoother innovation adoption. This alignment not only enhances trust but also ensures that digital public infrastructures are designed with inclusivity and accessibility in mind, addressing societal challenges such as the digital divide (Frumkin and Galaskiewicz, 2004).

The expectation, therefore, is that a higher degree of diversity mirroring between public administrations, cit-

izens, and technology solution providers will lead to a greater probability of successful diffusion of innovation. This dynamic exemplifies the interconnectedness of diversity, representation, and innovation, sketching around the need for public institutions to prioritize diversity as a core component of their digital transformation strategies.

2.3. Government Technology - GovTech

Government technology - or GovTech - has emerged as a promising trend to address the restrictions faced by public administrations in attaining technology-driven innovation (Bharosa, 2022). By creating partnerships between public and private actors, GovTech offers an alternative pathway for digital transformation, bypassing the challenges inherent in traditional public sector structures (Bharosa and Janowski, 2024; Niehaves and Klassen, 2024). Defined by the European Union as "*technology-based cooperation[s] between public and private sector actors supporting public sector digital transformation*", the concept is further refined to focus on startups and small- to medium-sized enterprises (SMEs) (of the European Union, 2024). These dynamic entities are seen as key players in driving future technology innovation diffusion within the public sector.

In the broader sense, GovTech represents the most recent wave of emerging technology markets, with an estimated market size exceeding 50 billion € in Europe alone (Fund, 2024; Selke et al., 2024). The sector is largely driven by small-scale entrepreneurs who provide innovative technology solutions without relying on the dominant influence of BigTech actors (Niehaves and Klassen, 2024). This independence not only fosters competition but also enhances the diversity of ideas and approaches available for public sector transformation (Kolain and Hillemann, 2022). Startups within the GovTech ecosystem are often deeply personal ventures, reflecting the values, creativity, and diversity of their founders (Isenberg, 2010). This founder-driven ethos imbues GovTech solutions with unique perspectives, further emphasizing the role of diversity in driving innovation (Bharosa, 2022; Nose, 2023).

According to Bharosa (2022), GovTech ventures promise higher levels of citizen centrism and deliver direct value to the recipients of public services. This citizen-centric focus underscores the importance of diversity within GovTech teams, as their composition directly influences the inclusivity and relevance of the solutions they develop (Isenberg, 2010; Nose, 2023). The diversity at the highest levels of these organizations can ensure that public services are designed to meet the varied needs of the populations they serve.

Striving for higher degrees of diversity within GovTech teams is essential to align with the broader goals of diversity management discussed earlier. This alignment may be necessary so that the solutions procured by public administrations not only reflect the values of inclusivity but are also developed by teams that embody those values. As GovTech continues to grow as a sector, the emphasis on diversity—both within the teams and the solutions they offer—will play a critical role in shaping its impact on public sector digital transformation and societal progress (Edquist and Zabala-Iturriagagoitia, 2012).

To summarize, this study exploratorily investigates how diversity within GovTech compares to public administrations and the citizenry, examining key dimensions such as gender, migration background, and socioeconomic status. The findings highlight significant disparities between these groups, emphasizing the critical role of representation in fostering equity and innovation in public sector digital transformation.

Building on the theoretical insights into diversity management and diffusion of innovation in the context of GovTech, the following section outlines the methodological approach of this study. We then report the findings, describing diversity metrics across the examined groups. In the discussion section, we comprehensively discuss the results, addressing implications for practice and policy. Finally, we outline limitations and propose directions for future research.

3. Data and Methods

To collect data on diversity attributes, previous research suggests three primary methods : 1) using publicly available data through social media outlets, e.g., LinkedIn (Hickey et al., 2022), 2) conducting surveys, e.g., Statista (2024) (Wise and Tschirhart, 2000), or 3) data collection through expert interviews, e.g., self-collected information available in this paper (Schultze and Avital, 2011).

For the current study, we collect data using a combination of survey and expert interview approaches. Data on diversity attributes among GovTech founders in Germany were collected as part of a larger qualitative study to examine GovTech success factors. We conducted interviews with 108 GovTech founders where we also gathered specific information on diversity attributes (i.e. distribution of gender, migration background and labor background in the composition of the founding teams) based on a questionnaire. From these 108 interviewees, we received 100 responses to the questions on diversity attributes of 238 GovTech-founders. To compare the data with the diversity structure of GovTech clients and services recipients (i.e., startups in general, public administration employees, and citizen demographics), we retrieved data from publicly available sources with a temporal variance of one to three years due to differing data availability. In particular, the data sets were sourced from Bertelsmann Stiftung (2024), Bundesinstitut für Bevölkerungsforschung (BiB) (2022), Bundesverband Deutsche Startups e.V. (2023), and Statista (2023, 2024) and Statista (2021).

For the following paper we use founders self-assessment for the named dimensions without further discussion or elaboration. In general an understanding of the three dimensions had emerged as:

Gender: A social and cultural construct that classifies individuals based on characteristics typically associated with masculinity and femininity, often aligning with but distinct from biological sex. In the study, we did not find any non-binary attributed founders.

Migration Background: Refers to individuals who are either immigrants themselves or have at least one parent born outside the country of residence, encompassing both first- and second-generation migrants.

Labor (or Academic) Background: Denotes an individual's parents employment history, occupational status, or socioeconomic position related to the labor market, often shaped by factors such as education, job type, and industry. Here we included only founders as labor background individuals, whose parents were both non-academic.

4. Results

Table 1 shows an descriptive overview of the distributions of diversity attributes across GovTech founders, startups in general, public administration employees, and citizen demographics. To statistically account for the overall discrepancies between the proportions of diversity attributes across the groups, we performed χ^2-tests (see below). Note that, gender is attributed as binary, as information provided by GovTech founders and publicly available statistics only accounts for them. Migration is defined as per the European Unions understanding (European Migration Network, 2024).

Tab. 1 – Overview of the proportional distributions of diversity attributes across GovTech founders, startups, public administration employees, and citizen demographics. Key: m = male, f = female, nm = no migration background, mi = migration background, lb = labor background, and ab = academic background.

		Gender		**Migration background**		**Labor background**
GovTechs	m	85,7%	nm	77,3%	lb	62,8 %
	f	14,3%	mi	22,7%	ab	37,2%
Startups	m	79,0%	nm	70,0%	lb	54,5%
	f	21,0%	mi	21,0%	ab	45,5%
Public administration	m	41,4%	nm	92,0%	lb	./.
	f	58,6%	mi	8,0%	ab	./.
Citizens	m	50,7%	nm	71,4%	lb	72,2%
	f	49,3%	mi	28,6%	ab	27,8%

4.1. Gender Differences

Interview information and further data sourced from Bundesinstitut für Bevölkerungsforschung (BiB) (2022) and Statista (2024) were included in the analysis. The χ^2-test revealed a highly significant difference in the proportion of males and females across GovTechs, startups, public administration and citizens ($\chi^2 = 60.19, p < 0.001$) indicating that the distribution of gender differs significantly depending on the group.

In GovTech startups, 85.7% of founders identify as male, while only 14.3% identify as female, see Figure 1). This is slightly higher than the gender distribution in startups more broadly, where 79% of founders identify as male and 21% as female. In comparison, public administration employees demonstrate a starkly different distribution, with 41.4% identifying as male and 58.6% as female, aligning more closely with the near-equal gender distribution among the general citizen population (50.7% male, 49.3% female).

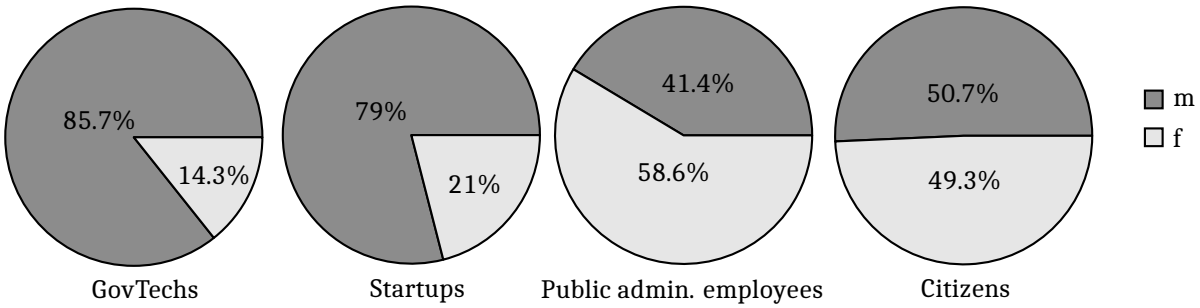

Fig. 1 – Distribution of founders' gender identification in Germany (dark=male, light=female).

The pronounced gender disparity in GovTech startups suggests potential barriers to female participation at the entrepreneurial level. This imbalance may limit the diversity of perspectives in GovTech solutions, potentially impacting their inclusivity and effectiveness. Public administrations, with a higher representation of women, could serve as a model or partner to promote more gender-equitable practices in the GovTech sector.

4.2. Migration Background

The analysis of the combined data from interviews and Bundesinstitut für Bevölkerungsforschung (BiB) (2022), Bundesverband Deutsche Startups e.V. (2023), and Statista (2023) showed a significant difference of the proportions of people having a migration background across the groups ($\chi^2 = 14.16, p < 0.01$). This suggests that the migration distribution varies significantly across the categories.

In particular, the data indicate that 22.7% of GovTech founders have a migration background, closely mirroring the 21% found in the broader startup ecosystem. In stark contrast, only 8% of public administration employees report having a migration background, compared to 28.6% of the general citizen population, see Figure 2. This gap between public institutions and the citizenry they serve raises concerns about representation.

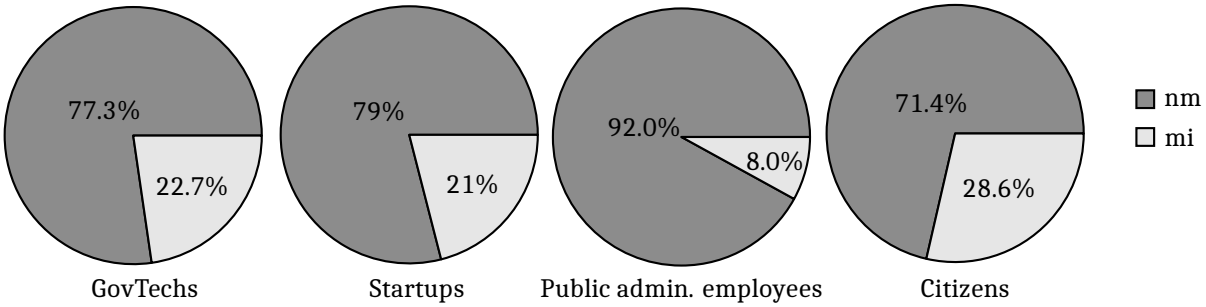

Fig. 2 – Distribution of founders' with migration background in Germany (dark=no migration, light=migration).

The relatively low presence of individuals with migration backgrounds in public administrations highlights a significant underrepresentation issue. This discrepancy could hinder the ability of public institutions to address the needs of diverse populations effectively. The alignment of GovTech startups with general startup migration demographics indicates a potential avenue for fostering innovation through more diverse team compositions, but might also hint at potential pitfalls for similarity-driven acceptance of solution procurement teams in public administrations.

4.3. Labor Background

For the labor background diversity attribute, the χ^2-test showed a significant difference between the distributions ($\chi^2 = 6.75, p < 0.05$) indicating that the proportions of individuals with labor backgrounds differ significantly across the groups. Note that we have excluded missing values of public administration employees. In addition to the data collected during our interviews, we retrieved data from Bertelsmann Stiftung (2024) and Statista (2021).

In particular, the data indicates that 62.8% of GovTech founders come from labor backgrounds, while 37.2% have academic backgrounds, see Figure 3. Startups overall show a slightly more balanced distribution, with 54.5% from labor backgrounds and 45.5% from academic ones. Unfortunately, no detailed data on the labor or academic backgrounds of public administration employees was available for comparison. Among the general citizenry, 72.2% have labor backgrounds, while 27.8% have academic backgrounds.

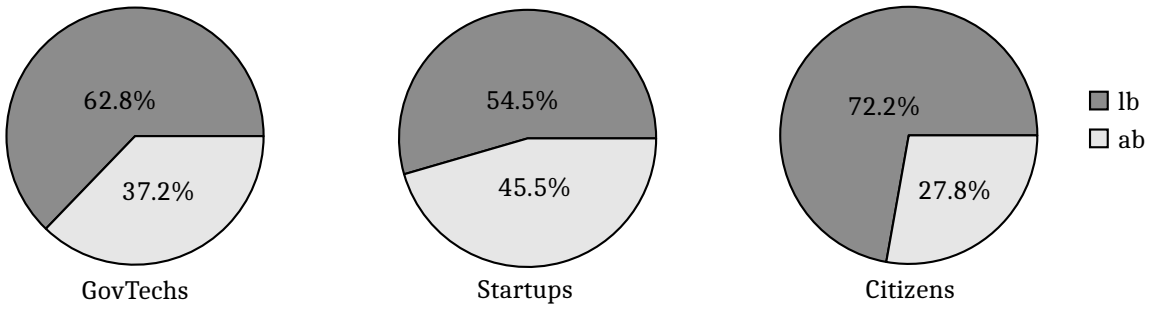

Fig. 3 – Distribution of founders' with labor background in Germany (dark=labor, light=academic).

The high proportion of GovTech founders with labor backgrounds underscores the accessibility of the GovTech sector for individuals outside traditional academic pathways. This inclusivity may foster practical, grounded solutions. However, the absence of equivalent data for public administration employees highlights a need for further research to assess how aligned public institutions are with the populations they serve.

4.4. Generalization of Findings

Our study show significant disparities in diversity across GovTech startups, public administration, and citizen demographics, depicting both opportunities and challenges in achieving equity and representation. They carry relevant implications for the GovTech sector and its potential to drive inclusive digital transformation (Bharosa, 2022).

Gender representation: The stark gender disparity in GovTech startups, with only 14.3% of founders identifying as female, contrasts sharply with the more balanced gender distribution in public administrations (58.6% female). This disparity limits the diversity of perspectives in GovTech leadership and, consequently, the inclusivity of the solutions developed. Given that GovTech ventures are deeply founder-driven, this underrepresentation likely influences the prioritization of user needs in GovTech solutions. Addressing gender diversity in the GovTech ecosystem may show to be an inhibitor to fostering more citizen-centric innovations that resonate with diverse end-users. Public administrations, with their comparatively higher representation of women, could serve as key partners in advocating for more gender-equitable practices in GovTech teams.

Migration backgrounds: The underrepresentation of individuals with migration backgrounds in public administrations (8%) compared to the general citizen population (28.6%) is another critical gap. In contrast, GovTech startups exhibit relatively higher diversity, with 22.7% of founders having migration backgrounds, aligning more closely with citizen demographics. This alignment positions GovTech as a promising avenue for amplifying diverse voices and addressing societal needs that may be overlooked in less representative public institutions.

Labor and academic backgrounds: The high representation of individuals from labor backgrounds among GovTech founders (62.8%) contrasts with broader societal trends, where labor-background representation in professional leadership roles is typically lower. This inclusivity in GovTech shows a potential avenue to serve

as a platform for practical and grounded innovation, often driven by founders' lived experiences. However, the lack of comparable data for public administration employees creates a blind spot in understanding the socio-economic alignment between public institutions and the populations they serve. As GovTech teams develop solutions for public sector challenges, their diverse socio-economic backgrounds may offer advantages in crafting solutions that address real-world needs effectively, but there is a need for additional data.

5. Discussion

The findings highlight a complex landscape of representation across GovTech startups, the broader startup ecosystem, public administration, and citizen demographics. These differences in representation reveal both challenges and opportunities for the GovTech sector in addressing diversity and fostering innovation (Bharosa, 2022; Niehaves and Klassen, 2024).

GovTech startups exhibit the closest resemblance to the broader startup ecosystem in terms of diversity metrics, such as gender, migration background, and socio-economic representation. This alignment underscores the entrepreneurial roots of GovTech as a sector driven by small-scale innovators who share the characteristics and challenges of startups in general (Isenberg, 2010). However, in some areas GovTech teams diverge significantly from public administration employees and the citizens they aim to serve (Bharosa, 2022). For example, public administrations display greater gender parity but are less representative of migration diversity, while GovTech founders exhibit high socio-economic diversity but lower gender and migration balance.

These discrepancies suggest that while GovTech startups are reflective of entrepreneurial norms, they fall short of mirroring the diversity of the populations their solutions target. Public administrations, on the other hand, are more aligned with societal expectations for inclusivity in certain areas, such as gender, but fail to address other critical aspects of representation, such as migration and socio-economic background diversity. This divergence raises questions about where representation matters most and how alignment can be improved across these groups.

The relevance of representation is arguably highest at the point of citizen interaction, where digital public infrastructure solutions directly impact the lives of diverse communities (Bharosa and Janowski, 2024; Frumkin and Galaskiewicz, 2004). GovTech startups, as providers of these solutions, must embody the diversity of their end-users to ensure their products are inclusive, accessible, and effective (Bharosa, 2022). Similarly, public administrations, as the procurers and implementers of GovTech solutions, must prioritize diversity to align their governance and oversight with the needs of the populations they represent.

The current alignment of GovTech startups with the broader startup ecosystem rather than with their client base (public administrations) or end-users (citizens) presents a misalignment that may limit the inclusivity and societal relevance of their solutions (Nose, 2023). Representation within GovTech teams is not only a matter of equity but also a critical factor in fostering trust, collaboration, and innovation. Diverse teams are better equipped to understand and address the multifaceted challenges faced by marginalized groups, enabling the development of more equitable digital public infrastructures (Bassett-Jones, 2005).

Several factors contribute to the observed disparities in representation. In GovTech startups, entrepreneurial norms and the reliance on founder-driven ventures often perpetuate existing patterns of underrepresentation, particularly in terms of gender and migration backgrounds, as these often are counter-elite indicators. These challenges are compounded by systemic barriers, such as limited access to capital and networks for underrepresented groups, which affect participation in the broader startup ecosystem (Isenberg, 2010).

Public administrations, while more structured and inclusive in certain areas, face their own constraints. Bureaucratic inertia, limited recruitment pipelines, and historical biases have contributed to a lack of diversity, particularly in migration and socio-economic backgrounds. These disparities are further exacerbated by the aging workforce and difficulties in attracting younger, more diverse talent (Niehaves, 2011).

To fully realize the potential of GovTech as a driver of public sector innovation, deliberate efforts are needed to address these disparities and align diversity metrics across GovTech teams, public administrations, and the citizens they serve. GovTech startups must prioritize diversity in their leadership and team composition, ensuring that their solutions reflect the needs of diverse communities. Public administrations, as procurers and

partners, play a role in incentivizing this shift by embedding diversity requirements into procurement processes and fostering partnerships with startups that embody inclusive values (Grandia and Meehan, 2017). Previous work indicates an already existing under-representation in female founded ventures in public procurement (Saunders, 2022). As such we see a general trend, that needs to be a addressed. A diversity centered may approach not only strengthens the societal relevance of digital public infrastructure solutions but also build trust and collaboration between public institutions, GovTech startups, and citizens.

6. Limitations and Outlook

The relevance of exploring diversity in GovTech and its alignment with public administration and citizen demographics cannot be overstated. As digital public infrastructures play an increasingly vital role in shaping societal outcomes, understanding how diversity impacts the design, procurement, and delivery of these solutions is essential for fostering inclusivity and equity (Bassett-Jones, 2005; Bharosa, 2022; Bharosa and Janowski, 2024). This study provides an initial overview on alignments and misalignments in representation within one national example, highlighting strengths and gaps within the GovTech sector, public administrations, and their potential interactions with the populations they serve.

Our findings reveal strong alignments between GovTech startups and the broader startup ecosystem, particularly regarding migration and socio-economic diversity (Isenberg, 2010; Niehaves and Klassen, 2024). However, GovTech diverges markedly from public administrations and citizens in terms of gender representation, while public administrations demonstrate notable underrepresentation of migration and socio-economic diversity compared to the citizenry. As such, we were able to exemplarily answer the first part of our research question. Nevertheless, our descriptive data - combined with previous literature - is insufficient to draw substantiated conclusions on the effects this might entail. We see a need for further qualitative research and sense making.

Another critical limitation of this study is the piecing together of data from differing sources. As no research has yet been conducted on our topic, we had to included data from different outlets as well as within a one and a half year timespan between publication. This limits quality and is intensified by the absence of detailed data on the labor and academic backgrounds of public administration employees. Without this information, it remains challenging to assess the socio-economic alignment of public institutions with the populations they represent. Future research must address this gap to provide a more comprehensive understanding of diversity dynamics in public sector organizations.

Additionally, the study's focus on a single country with strong public administrations limits its generalizability. An international comparison would offer valuable insights into how diverse governance contexts influence representation and innovation dynamics in GovTech. This is especially relevant, as both GovTech definitions are used politically motivated depending on the national contexts (Bharosa, 2022; Niehaves and Klassen, 2024), national metrics of migration and and academic versus labor, and public administrations culture differ greatly between national contexts. Such comparisons could reveal best practices and provide a broader foundation for understanding how diversity impacts digital public infrastructure globally.

Further data collection is essential to deepen our understanding of the factors driving discrepancies in representation across groups. Key areas for exploration include: 1) The reasons for observed discrepancies, particularly systemic barriers and organizational practices that hinder diversity. 2) The relative relevance of diversity dimensions, such as gender, migration background, and socio-economic status, from the perspectives of both public administrations and citizens. 3) Potential management practices that public institutions and GovTech startups can adopt to address diversity shortcomings and foster more inclusive ecosystems.

One promising approach for addressing these gaps is the use of focus groups that include representatives from all four groups—GovTechs, public administrations, citizens, and startups in geneal (Belanger et al., 2012; Conboy et al., 2012). These discussions could serve as a platform for evaluating the interplay between diversity, representation, and innovation, generating actionable insights and fostering collaborative problem-solving.

This study relies on descriptive statistics, providing an essential but limited foundation for understanding the complexities of diversity in GovTech. While these statistics offer valuable insights into the current state of representation, they do not capture the underlying dynamics or causal relationships that drive the observed pat-

terns. Future research may adopt mixed methods approaches, integrating qualitative and quantitative analyses to explore further topics relating diversity in GovTech.

Abstract. Digital transformation in public administration is increasingly driven by GovTech startups, which leverage innovative technologies to address complex societal and administrative challenges. Despite their growing importance, the business models underlying these startups remain poorly understood, limiting their effective integration into public sector ecosystems. While existing research focuses on defining GovTech and exploring its potential, little attention has been paid to the systematic analysis of the business models that enable these startups to align technological innovation with the unique requirements of public administration. Addressing this gap, our study develops a taxonomy of GovTech business models to provide clarity and actionable insights for stakeholders. Our research identifies 11 dimensions and 55 characteristics that structure the business models of GovTech startups, emphasizing meta-dimensions such as value proposition, value creation and delivery, and value capture. These insights offer a comprehensive framework to classify and analyse the diverse approaches within the GovTech sector. By analysing 85 GovTech startups in Germany through an iterative taxonomy development process, we reveal distinct patterns in areas such as funding strategies, stakeholder alignment, technological enablers, and operational scope. The taxonomy highlights how GovTech startups address key challenges like citizen engagement, operational efficiency, and compliance assistance, providing practical examples of successful implementations. This study contributes to both theory and practice by offering a structured understanding of GovTech business models. For researchers, the taxonomy provides a foundation for further exploration of this emerging field. For practitioners and policymakers, it serves as a strategic tool to foster public-private collaboration, optimize innovation adoption, and address public sector challenges in a dynamic environment.

1. Introduction

Governments play a central role in addressing complex societal challenges, yet they struggle to adapt their services to the demands of an increasingly digital world. While public institutions traditionally monopolized service provision, emerging technologies such as artificial intelligence (AI), the Internet of Things (IoT), and blockchain are reshaping this landscape. However, financial constraints, regulatory complexity, and a lack of technical expertise hinder their adoption (Bharosa, 2022). As standardized IT solutions often fail to meet the public sector's evolving needs, governments increasingly rely on GovTech startups to drive digital transformation. These startups offer agile, tailored solutions for key challenges such as digital identity management, smart infrastructure, and real-time data processing (Mergel et al., 2022). With a rapidly growing market—valued at 19.8 billion euros in Germany and 411 billion euros globally in 2021 (Public, 2021)—GovTech has become a key driver of public sector modernization, as demonstrated by successful innovations like *Vialytics'* smart road damage detection system (Stuck & Dieke, 2023).

Despite the growing importance of GovTech, successful collaborations between startups and government institutions remain limited, largely due to the uncertainty of GovTech business models. Unlike industry firms, startups in this sector face complex procurement processes, rigid regulatory frameworks, and long decision cycles, making it difficult to establish sustainable revenue streams (Hoekstra et al., 2023). Bureaucratic hurdles and varying digital maturity among public institutions further hinder scalability, leaving many promising innovations unable to gain traction (Kuziemski et al., 2022; Mergel et al., 2022). Without a clearer understanding of how GovTech startups can structure viable business models, governments risk missing out on critical technological advancements (Bharosa, 2022).

While existing research provides valuable insights into the technological applications, regulatory landscape, and ecosystem dynamics of GovTech, it falls short in addressing the business models that enable startups to navigate this complex sector. Studies on AI and blockchain in public administration highlight technological capabilities but overlook the structural barriers that GovTech startups face in scaling their solutions (Androutsopoulou et al., 2019; Engin & Treleaven, 2018). Research on GovTech ecosystems and their relationship to CivicTech (Yoshida & Thammetar, 2021) provides a macro-level perspective but lacks granularity in explaining how startups establish viable revenue models and sustain long-term collaborations with government institutions. While regulatory and market studies (Kuziemski et al., 2022; Mergel et al., 2022) acknowledge institutional constraints, they do not systematically classify the strategies startups use to overcome them. This disconnect underscores the need for a structured framework that captures the defining characteristics of GovTech startup business models. Without such an understanding, both academic research and policy discussions risk remaining too abstract to inform actionable strategies for fostering startup-driven public sector innovation.

While GovTech is gaining significance, research has yet to systematically classify the business models that enable startups to navigate technological innovation, regulatory requirements, and government procurement processes. Existing studies provide insights into ecosystem dynamics, regulatory challenges, and technological applications but do not comprehensively analyse the structural characteristics that shape GovTech business models (Bharosa, 2022). Given the sector's distinct challenges, including long procurement cycles, fragmented public sector demand, and reliance on public funding (Filer, 2019; Mergel et al., 2022), a deeper understanding of how these startups establish and sustain operations is necessary. Clarifying the key components of GovTech business models can enhance both academic inquiry and practical decision-making, supporting more effective collaborations between startups and government institutions. Against this backdrop, this study answers: *what conceptually grounded and empirically validated characteristics structure the business models of GovTech startups?*

To investigate this research question, we conduct a case-based analysis of GovTech startups in Germany, examining their business models to identify key characteristics. A case study approach captures the complexity of GovTech operations, while a purposive sampling strategy ensures diversity in sectors, technologies, and collaboration models. Data is drawn from company reports, industry analyses, and specialised databases, providing a comprehensive foundation. To structure findings, we apply an iterative taxonomy development approach (Nickerson et al., 2013), integrating theoretical insights with empirical observations.

The final taxonomy of GovTech startup business models consists of three meta-dimensions—*value proposition, value creation and delivery,* and *value capture*—covering 11 dimensions and 55 characteristics. It highlights the diversity of GovTech models and their strategies for public sector collaboration. In value proposition, startups focus on areas such as data-driven decision support and compliance, exemplified by *GovShare's* knowledge exchange and *Trail's* AI-powered automation. Value creation and delivery shows varying technological adoption, from established solutions to advanced AI and blockchain, with integration levels ranging from independent providers like *Breeze Technologies* to co-created solutions like *Convaise*. Value capture reflects financial constraints, with many startups relying on mixed funding and subscription models, while others lack clear revenue structures. This taxonomy offers a structured framework to analyse how GovTech startups develop, deliver, and sustain their services.

This study advances the understanding of GovTech startup business models by providing a structured taxonomy across value proposition, value creation and delivery, and value capture. It extends existing research on public sector innovation (Bharosa, 2022; Mergel et al., 2022) by identifying structural barriers such as limited openness, reliance on basic technology, and challenges in public sector integration. The findings refine business model frameworks for regulated environments (Wirtz et al., 2016) and offer practical insights for policymakers to foster startup-government collaboration. For entrepreneurs, the taxonomy provides strategic guidance on aligning business models with government needs and funding structures.

2. Theoretical Background

2.1 GovTech

GovTech, an acronym for "government" and "technology," (Bharosa, 2022) represents an emerging wave of digital transformation aimed at modernizing public sector operations through innovative socio-technical solutions. Unlike traditional e-government initiatives, which often rely on in-house development or large vendors, GovTech emphasizes the agility and innovation of startups and small and medium-sized enterprises (SMEs) to address public sector challenges (Mergel et al., 2022). The core technological competencies encompass AI, blockchain, big data analytics, cloud computing, predictive analytics, and the IoT (Dener et al., 2021; Engin & Treleaven, 2018). GovTech startups utilize these technologies to create public value by improving administrative processes, promoting citizen participation, enabling transparent governance, and contributing to the reduction of corruption risks (Santiso, 2022). A key characteristic of GovTech is its collaborative nature, where private organizations work closely with public sector entities to co-create value. This collaboration leverages the technological agility of private firms and aligns it with the mission-oriented focus of government agencies, enabling innovations that address complex societal needs (Bharosa, 2022).

GovTech has been defined in various ways (Mergel et al., 2022), highlighting different aspects such as collaboration with startups and SMEs (e.g., Filer, 2019), the use of innovative technology (e.g., Accenture & Public, 2018), and the improvement of efficiency in public administration (e.g., Yoshida & Thammetar, 2021). To navigate this conceptual variety, we follow the definition by Bharosa (2022, p. 3): "GovTech refers to socio-technical solutions – that are developed and operated by private organisations – intertwined with public sector components for facilitating processes in the public sector." This definition is particularly suitable for our purposes as it captures both the technological and organizational dimensions of GovTech and emphasizes the interdependence of public and private actors.

Despite its potential, the adoption of GovTech solutions faces several challenges. Public sector organizations often operate within rigid bureaucratic structures and stringent regulatory frameworks, making it difficult to implement agile and innovative solutions (Bharosa & Janowski, 2024). Additionally, traditional procurement processes are not well-suited for engaging startups, limiting governments' access to cutting-edge technologies (Filer, 2019; OECD, 2019). This "paradox of high potential but low adoption" underscores the importance of addressing barriers such as risk aversion, technical expertise deficits, and regulatory constraints (Hoekstra et al., 2023).

2.2 Business Models

The concept of the business model has been extensively explored in academic and practical domains since the 1990s, serving as both a theoretical framework and a practical tool for analysing and guiding business practices (Massa et al., 2017; Zott et al., 2011). Despite its widespread adoption, there remains a lack of consensus on its precise definition, leading to a variety of interpretations and frameworks. Scholars have proposed both simplified and comprehensive definitions, aiming to either focus on specific aspects or encompass the intricate interdependencies within business model elements (Foss & Saebi, 2017; Wirtz et al., 2016).

One of the earliest and most influential definitions by Chesbrough and Rosenbloom (2002) conceptualizes the business model as a mechanism for transforming technological potential into economic value by mediating between technological inputs and market demands. This perspective underscores the centrality of the business model in translating innovation into market success. Similarly, Teece (2010) defines a business model as a coherent framework that articulates the logic and evidence demonstrating how value is created, delivered, and captured. This widely accepted definition emphasizes three core components:

- **Value Proposition:** Identifies the problems a company solves for its customers and the needs it satisfies (Osterwalder & Pigneur, 2010; Wirtz et al., 2016).
- **Value Creation and Delivery:** Describes the organization of resources and key activities necessary to realize the proposed value (Teece, 2010).
- **Value Capture:** Focuses on how revenue is generated and managed alongside the associated cost structure (Teece, 2010; Wirtz et al., 2016).

The interconnected nature of these elements underscores the dynamic interdependencies within business models,

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

where changes in one dimension can significantly affect the others (Johnson et al., 2008).

With the rise of digital technologies, the concept of digital business models has gained increasing attention in Information Systems (IS) research (Sawy & Pereira, 2013). Digital business models leverage technological advancements to reshape how businesses operate and generate revenue. A defining feature of digital business models is their scalability and minimal reliance on physical assets, enabling businesses to offer highly personalized and efficient services at low marginal costs (Remane et al., 2022).

These advancements are especially relevant in sectors like GovTech, where digital tools enable more efficient governance, better public service delivery, and improved citizen interaction (Bharosa, 2022; Mergel et al., 2022). By facilitating innovative approaches to public sector modernization, digital business models play a pivotal role in addressing evolving societal needs.

3. Method

To ensure both practical relevance and scientific rigor, we employed design science research and utilized it as a guideline to elaborate further details of this research (Hevner, 2007; Hevner et al., 2004). Design science research is particularly well-suited for research aimed at developing and evaluating artifacts that address real-world challenges while contributing to the theoretical knowledge base (Hevner et al., 2004). This approach is applied to guide the iterative development of a taxonomy of GovTech startup business models, integrating insights from theoretical and empirical sources.

Taxonomy development is operated through three interrelated cycles: the rigor cycle, the relevance cycle, and the design cycle. The rigor cycle provides the theoretical foundation for the research by synthesizing existing literature and leveraging prior knowledge. The relevance cycle ensures the practical grounding of the research by testing the developed knowledge in real-world contexts. The design cycle serves as the iterative core of the research, where artifacts are continuously evaluated and refined based on inputs from both the rigor and relevance cycles. These three cycles are interconnected and ensure that the research process is both comprehensive and aligned with the study's objectives. Figure 1 illustrates these cycles and their respective activities.

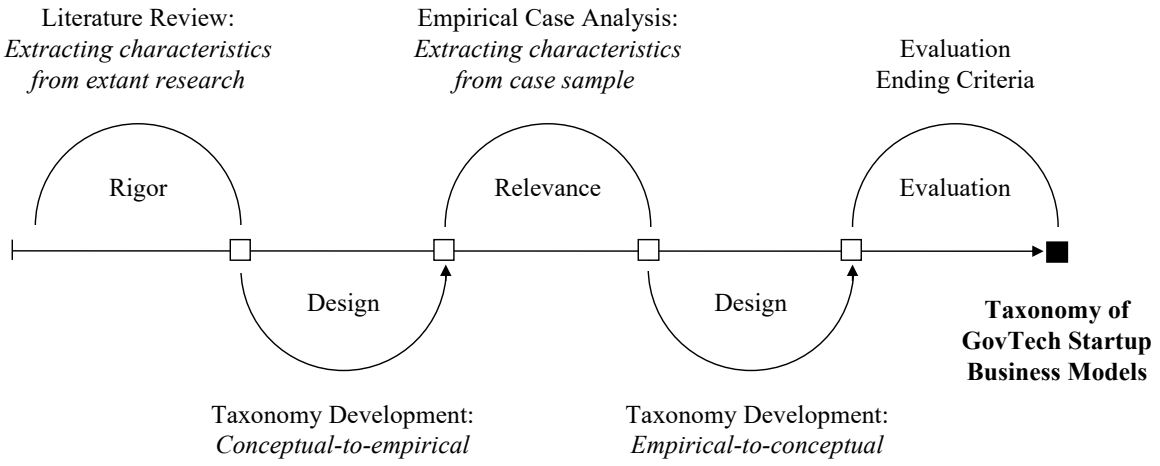

Fig. 1 - Iterative Design Science Cycles and Activities for Taxonomy Development.

The core of the design cycle is the taxonomy development method by Nickerson et al. (2013). This process develops a taxonomy with iterations from empirical-to-conceptual or conceptual-to-empirical until predefined ending-conditions are met. Nickerson et al. (2013) emphasized the importance of defining meta-characteristics at the very beginning since it eases the avoidance of examining many unrelated characteristics. The choice of meta-characteristics should be profoundly correlated with the taxonomy's purpose (Nickerson et al., 2013). In our case, the research purpose is to distinguish between various GovTech startup business models.

The **meta-characteristics** serve as the foundation for guiding the iterative development of the taxonomy and ensuring a structured and purpose-driven approach. As outlined by Nickerson et al. (2013), the meta-characteristic must represent the most comprehensive feature that aligns with the taxonomy's purpose and the needs of its users. For this research, the taxonomy is designed to assist stakeholders, including investors, public sector representatives, entrepreneurs, and researchers, in identifying, categorizing, and differentiating GovTech startups based on their business models. Accordingly, the meta-characteristic was defined as the identification of distinctive features within GovTech business models, encompassing universal business model components value proposition,

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

value creation and delivery, and value capture (Wirtz et al., 2016). This focus ensures that the taxonomy remains relevant to its primary users' needs, such as evaluating growth potential and scalability for investors, identifying tailored solutions for public sector challenges, and facilitating strategic differentiation for entrepreneurs. Grounded in prior studies across domains like AI startups (Weber et al., 2022), FinTech (Eickhoff et al., 2017), and blockchain startups (Weking et al., 2019), the meta-characteristic provides a universal framework for refining subsequent dimensions and characteristics, ensuring all elements logically stem from this foundational principle.

Ending conditions determine the point at which the taxonomy can be considered complete, providing clear criteria for concluding the iterative refinement process. Following Nickerson et al. (2013), this research adopts a dual approach by integrating both objective and subjective ending conditions. Objective criteria evaluate the taxonomy's structural integrity, ensuring that all objects can be classified, no dimensions or characteristics were added, merged, or split in the last iteration, and each dimension and characteristic is unique and relevant. Subjective conditions, on the other hand, focus on the taxonomy's utility, assessing its conciseness, robustness, comprehensiveness, extendibility, and explanatory power. By meeting these conditions, the taxonomy achieves a balance between structural rigor and practical relevance. Notably, this study incorporates universal business model components—value proposition, value creation and delivery, and value capture—as guiding principles throughout the iterative cycles. By doing so, the taxonomy avoids neglecting critical dimensions or characteristics, particularly those relevant to the physical environment of the public sector, ensuring a robust and contextually appropriate framework for GovTech startup classification.

The **rigor cycle** begins with a systematic literature review to provide a robust theoretical foundation for the taxonomy development. Following the methodology by Webster and Watson (2002), the literature review focuses on two key domains: GovTech and business model theory. The first step involved keyword-based searches in prominent academic databases, including Scopus, Web of Science, and IEEE Xplore. To ensure high-quality results, we targeted articles ranked as A+, A, or B in the VHB-JOURQUAL3 classification (VHB, 2022) and included relevant contributions from the Association for Information Systems (AIS) Special Interest Group on E-Government (AIS, 2011). The search string combined the keywords: "business model" AND ("digital government" OR "GovTech" OR "e-government" OR "government technology" OR "public sector"). This broad query minimized the risk of overlooking critical contributions and enabled a comprehensive understanding of the literature. Given the emerging nature of the GovTech field, grey literature sources such as industry reports and white papers were also included to supplement academic insights. This approach allowed for a more nuanced exploration of practical and theoretical dimensions in the domain. The initial search yielded 275 articles matching the search string in their title, abstract, or keywords. To refine this dataset, duplicate entries were first removed. Next, the titles and abstracts of the remaining articles were screened for relevance to the research domains. This process resulted in 41 articles. Further refinement through full-text screening reduced this number to 21 articles. In the subsequent step, a backward search was conducted, which involved reviewing the references cited in the selected articles, and a forward search, identifying articles that cited the selected publications. These efforts added 13 additional articles to the dataset. Therefore, the input of our rigor cycle was based on 34 journal articles or conference papers. The rigorous search and selection process ensured the inclusion of high-quality, relevant sources, providing a balanced mix of theoretical insights and practical applications.

In the **relevance cycle**, we extracted knowledge from real-world data and enhanced the practical consistency of our artifact. To achieve this, we followed a case survey guideline to ensure the sampling process is systematic, comprehensive, and theoretically sound (Larsson, 1993). For data collection, we selected Crunchbase as our initial data source, a widely recognized and comprehensive database with a focus on startups and innovative companies (Marra et al., 2015). Crunchbase has proven particularly useful for research on business model innovation in emerging markets, as it includes startups at all funding stages. Previous studies on successful taxonomy development have demonstrated the utility of Crunchbase data for similar research objectives (Weking et al., 2019). Using Crunchbase's filtering tools, we queried companies headquartered in Germany and tagged as GovTech under the Industries category, resulting in an initial list of 28 companies.

To enhance representativeness and address potential selection bias, we extended our search using multiple supplementary sources. These included blogs, articles, and reports identified via systematic web searches with keywords like "GovTech Startup." A key resource in this effort was the Berlin Startup Map, a dealroom-based platform that provided a list of 179 startups categorized as GovTech or CivicTech. Additionally, we identified 22 startups through participation in GovTech-specific events, such as the GovTech Tag 2022. Combining all sources, we compiled a preliminary sample of 209 startups headquartered in Germany.

We applied stringent inclusion criteria to this sample to ensure alignment with the research objectives. Verification involved a detailed examination of publicly available information, including startups' websites, press releases, and other supporting materials. This step confirmed the startups' classification as GovTech entities and verified their operational status and location in Germany. Further criteria included assessments of the startups' founding year, growth potential, and innovation in technology or business model to validate their classification as startups.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Following this rigorous screening process, 85 startups met all criteria and were included in the final sample. The substantial reduction in sample size was primarily due to entries from the Berlin Startup Map that did not meet the inclusion criteria. In rare instances, specific criteria, such as age limits, were relaxed when a startup's business model demonstrated strong alignment with GovTech, and its classification as a startup was consistently confirmed across multiple sources. These exceptions were applied sparingly and with careful consideration to preserve the theoretical integrity of the GovTech sector.

The final sample, along with links to their websites, is listed in Table 3 in the appendix. This structured and multi-sourced approach ensured a solid and representative sample for the development of our taxonomy. These empirical data served as input for the iterative refinement of the taxonomy.

The **design cycle** is the core of the research and follows the taxonomy development methodology by Nickerson et al. (2013). This iterative refinement process was initiated following the definition of meta-characteristics and termination conditions. This involved alternating between conceptual-to-empirical (deductive) and empirical-to-conceptual (inductive) approaches to develop a taxonomy of GovTech business models. The deductive approach leveraged insights from existing literature to propose new dimensions and characteristics, while the inductive approach derived dimensions and characteristics through the analysis of empirical objects, in this case, GovTech startups. Each iteration evaluated the taxonomy against the defined termination conditions to ensure its progressive refinement (Nickerson et al., 2013).

In the first iteration, we employed a conceptual-to-empirical approach grounded in the presented literature review in the rigor cycle. To garnish the business model aspect of the taxonomy, we appended the following four dimensions: *proposed solution, key channels, revenue model*, and *target customer* that originated in Osterwalder and Pigneur (2010) and are frequently discussed by other researchers. Additionally, we added dimensions like *key technology* (Amit & Zott, 2010). GovTech-specific dimensions, including *solution domain* (Stuck & Dieke, 2023), *public sector integration, data activity, operational scope* (Bharosa, 2022), and *funding sources* (Mergel et al., 2022), were also introduced.

Using these insights, we developed the initial dimensions and characteristics for the taxonomy, resulting in a preliminary, purely conceptual taxonomy. The identified dimensions were mapped to overarching meta-dimensions based on the meta-characteristic of identifying distinctive features of GovTech startup business models. This structure encapsulated the key elements of GovTech startup business models, including *value proposition, value creation and delivery*, as well as *value capture*. Several dimensions were enriched with specific characteristics. For instance, the *solution domain* dimension included characteristics such as *smart urban infrastructure, environmental monitoring, civic engagement, health and social services,* and *internal administration* (Stuck & Dieke, 2023). The *data activity* dimension featured characteristics like *personalized service delivery* and *data-driven decision support* (Bharosa, 2022).

In subsequent iterations, an empirical-to-conceptual approach was adopted, involving the sequential analysis of 85 GovTech startups. The sample was divided into multiple phases, with each phase introducing new startups to validate and refine the taxonomy. An overview of a selection of the startups analysed is provided in Table 1.

Tab. 1 - Analysed GovTech Startups (Excerpt).

Startup	Description	Website
Convaise	Converts form-based communication between citizens and public authorities into intuitive chat interactions using conversational AI, thereby optimising administrative processes and improving accessibility of public services.	www.convaise.com
GovShare	It facilitates municipal climate protection by enabling local governments to exchange practical solutions and experiences on an open platform.	www.govshare.org
Vialytics	An AI-powered system that uses smartphone technology to help local governments better manage infrastructure by assessing road conditions and planning efficient maintenance.	www.vialytics.com

During the empirical analysis, several refinements were made to enhance the taxonomy. For example, the *collaboration level* dimension was reinterpreted as *public sector integration*, providing a clearer description of the degree of integration with public systems and workflows. Additionally, new dimensions were introduced, such as *openness*, which encompasses open data and open-source initiatives, and *key technology*. At the same time, less relevant dimensions, such as *cost structure,* were removed to streamline the taxonomy. Some existing dimensions were consolidated to improve the taxonomy's usability and relevance. For instance, the *product/service offering* and *sector focus* dimensions were merged into a broader *solution domain* dimension. These adjustments significantly improved the taxonomy's practical applicability for classifying GovTech startups.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

By the final iteration, all 85 startups had been analysed, and the taxonomy met all termination conditions. The finalized taxonomy successfully classified all startups, with every dimension and characteristic represented by at least one object. The iterative development process concluded once all objective and subjective termination conditions (Nickerson et al., 2013) were satisfied. The finalized taxonomy of GovTech startup business models is presented in detail in the results section.

4. Results

The final taxonomy of GovTech startup business models is presented in Table 2, visualized as a morphological box. In this framework, combinations of characteristics define the business model of a GovTech startup. The taxonomy comprises three meta-dimensions, eleven dimensions, and three to seven distinct characteristics per dimension, resulting in a total of 55 characteristics. Each dimension captures critical and distinctive elements of GovTech startup business models, structured around the overarching meta-characteristic that organizes business model components into the meta-dimensions of *value proposition*, *value creation and delivery*, and *value capture*. Selecting one characteristic from each dimension generates a unique profile for a GovTech startup's business model. The numbers in parentheses indicate the number of startups in our sample that exhibit the respective characteristic.

Tab. 2 – Taxonomy of GovTech Startup Business Models.

Meta-charact.	Dimension	Characteristics						
Value Proposition	Proposed Solution	Data-Driven Decision Support (22)	Collaboration and Knowledge Sharing (6)	Citizen Engagement (22)	Operational Efficiency (17)	Compliance Assistance (2)	Safety and Risk Management (6)	Data Control and Security (10)
	Solution Domain	Internal Admini-stration (18)	Citizen Services (25)	Education and Workforce Development (5)	Health and Social Services (2)	Smart Urban Infrastructure (18)	Defence and Safety (4)	Environ-mental Monitoring (13)
Value Creation and Delivery	Key Technology	AI and Advanced Analytics (24)	Blockchain (3)	IoT and Smart Sensors (10)	Cloud Computing (2)	Digital Twins (6)	Digital Identity (5)	Basic Technology Stack (33)
	Data Activity	Data Collection and Integration (19)	Personalized Service Delivery (27)	Data Analysis and Automation (26)	Data Sharing and Accessibility (10)	Data Governance and Security (3)		
	Key Channel	APIs and Modular Software (10)	Physical Devices (11)	Digital Platforms (64)				
	Public Sector Integration	Independent (36)	Partially Integrated (35)	Fully Customized (14)				
	Openness	Open Source (9)	Open Data (4)	Open Source and Open Data (2)	Proprietary (70)			
	Target Customer	B2G (42)	B2B (3)	B2C (8)	B2G and B2B (32)			
	Operational Scope	Municipal (38)	State (36)	International (11)				
Value Capture	Funding Sources	Private (28)	Public (13)	Mixed (8)	None or Undisclosed (36)			
	Revenue Model	Subscriptions and Licensing (31)	Non-Profit (2)	Transaction-based (3)	One-time Payment (6)	Consulting and Implementation Fees (4)	Undisclosed (39)	

Following Nickerson et al.'s (2013) recommendations, all dimensions are mutually exclusive to ensure clarity and applicability. For example, a startup cannot simultaneously be classified as leveraging *blockchain* and *digital twins* as its *key technology*.

Although multiple characteristics may theoretically apply to a single startup, each startup is assigned only one characteristic per dimension that fits best. This approach guarantees distinct classification within the taxonomy. Some dimensions, such as *funding sources*, are exhaustive and encompass all possible options for GovTech startups, while others, like *key technology*, reflect the most used technology.

The following sections detail each meta-dimension, its respective dimensions, and their defining characteristics, supplemented by examples from our empirical case sample.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

4.1 Value Proposition

The first meta-dimension, *value proposition*, explores the benefits that GovTech startups deliver to their stakeholders. This meta-dimension is captured through two distinct dimensions: *proposed solution* and *solution domain.*

The *proposed solution* dimension outlines the core benefits GovTech startups aim to provide, driving the digital transformation of the public sector by addressing specific stakeholder needs. These benefits include the leveraging *data-driven decision support* that enable public agencies to effectively analyse large amounts of data to make informed decisions. *Collaboration and knowledge sharing* enable stakeholders to exchange information and work together on governance challenges. *Citizen engagement* focus on improving the quality and ease of public interactions with governments. *Operational efficiency* help optimize resources and reduce expenditures in public services. *Compliance assistance* supports organizations in adhering to regulations and standards. *Safety and risk management* enhance the protection of public resources and infrastructure. Lastly, *data control and security* ensure that sensitive data is controlled and protected within legal frameworks. For example, *GovShare* facilitates intergovernmental knowledge sharing by offering a platform for best practice exchange, while Trail automates regulatory compliance processes through an AI-powered copilot.

The *solution domain* dimension categorizes the operational focus of GovTech startups, emphasizing the primary areas where solutions are applied. *Internal administration* streamlines internal processes within governmental organizations. *Citizen services* enhance public-facing services such as healthcare or transportation. *Education and workforce development* improve access to learning and employment opportunities. *Health and social services* address public health challenges and social welfare. *Smart urban infrastructure* focuses on optimizing city management and infrastructure development. *Defence and security* improve security measures and emergency response capabilities. *Environmental monitoring* addresses sustainability and ecological concerns. For instance, *JobKraftwerk* connects job seekers with employers via a digital platform, supporting workforce development, while *SONAH* uses sensor-based technology to provide actionable data for urban planning.

4.2 Value Creation and Delivery

The second meta-dimension, *value creation and delivery*, examines the mechanisms through which startups generate and deliver value. This meta-dimension is comprised of seven dimensions: *key technology, data activity, key channel, public sector integration, openness, target customer,* and *operational scope.*

The *key technology* dimension identifies the primary technologies that drive GovTech solutions. *AI and advanced analytics* enable predictive insights and process automation. *Blockchain* provides secure and distributed systems based on blockchain technology. *IoT and smart sensors* gather real-time data from physical environments. *Cloud computing* offers scalable storage and processing capabilities. *Digital twins* simulate and analyse spatial data. For example, *Edgeless Systems* uses cloud computing to protect sensitive data, while *Natix* incentivizes users to collect geospatial data via smartphones for real-time applications. *Digital identity* refers to secure and verifiable online identification solutions that enable citizens and businesses to authenticate themselves for government and private sector services, thereby improving security, accessibility, and compliance with legal frameworks. One example is *Verimi*, which offers a secure digital identity platform for storing and verifying ID documents and facilitates digital signatures, logins, and payments. At the same time, most of the startups (33) leverage a *basic technology stack*, utilizing established and widely adopted technologies without incorporating advanced or disruptive elements–e.g., basic web applications.

Data activity captures how startups engage with data. *Data collection and integration* involve aggregating information from diverse sources, such as sensors. *Personalized service delivery* tailors services to individual users. *Data analysis and automation* streamline processes through advanced analytics. *Data sharing and accessibility* improve collaboration across stakeholders. *Data governance and security* ensure compliance with data protection standards. For example, *Brifle* provides a personalized digital mailbox service, while *Natix* focuses on integrating and monetizing geospatial data.

The *key channel* dimension explores how GovTech startups deliver their solutions. *Application Programming Interfaces (APIs) and modular software* enable seamless integration with existing digital infrastructures by facilitating interoperability between different systems. *Physical devices* combines hardware solutions with software functionalities. *Digital platforms*, such as web and mobile applications, provide user-friendly interfaces for accessing services. For instance, *Green City Solutions* offers physical air purification devices, which use moss filters to bind particulate matter and provide real-time air quality data through IoT sensors.

Public sector integration highlights the extent of collaboration with government workflows. *Independent* startups operate without direct involvement from public sector entities. *Partially integrated* startups utilize public sector data or systems. Customized solutions are developed in close collaboration with government agencies. The

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

independent *Breeze Technologies* provides standardized air quality monitoring solutions, whereas *Convaise* collaborates with public entities to transition citizen communication into an individualized chat-based system.

Openness reflects the degree to which startups adopt open principles. *Open source* and *open data* promote transparency and collaboration, while *proprietary solutions* protect intellectual property. For example, *HeiDi* offers modular applications for municipalities based on open-source principles, enabling easy customization and integration with existing systems. The software is developed collaboratively with 334 municipalities and cities, making it cost-effective, efficient, and strengthening communities.

Target customer and *operational scope* examine the stakeholders served by GovTech startups. As *target customers,* GovTech startups address governments *(B2G)*, businesses *(B2B)*, or individual citizens *(B2C)*. Most of the GovTech startups in our sample target government intuitions. While 42 operate as a pure B2G business, another 32 have a mixed business and also address business customers *(B2G and B2B)*.

The *operational scope* dimension further explores at which scale their solutions apply, distinguishing between *municipal*, *state*, and *international* levels. For example, a startup might operate nationally but their solutions only apply to cities on a municipal level. With 38, most startups operate at the local level in communities, closely followed by the state level with 36 startups. *FixMyCity*, for example, exemplifies a municipal-level B2G startup enhancing public services for the general population by providing a platform for citizens to report and track the resolution of urban issues such as potholes or broken streetlights. Only 11 startups operate internationally.

4.3 Value Capture

The final meta-dimension, *value capture*, focuses on how GovTech startups sustain their operations and generate income. This meta-dimension includes two dimensions: *funding sources* and *revenue model*.

Funding sources refer to the mechanisms by which financial support for startups is provided. *Private funding*, the most frequently mentioned category with 28 startups, includes investments from individuals, institutions or organizations, including venture capitalists or crowdfunding efforts. *Public funding*, on the other hand, consists of government grants or subsidies aimed at promoting innovation and growth. *Mixed funding* represents a combination of different funding sources, reflecting a diversified approach to securing resources. Most startups did not disclose their funding details or did not receive any funding (36), making *none or undisclosed* the most common funding source observed in our sample.

Revenue model describes how startups generate income. *Subscription and licensing models*, which involve recurring payments for service access, are the most disclosed revenue models used by 31 startups. *Transaction-based models* charge customers per usage, while *one-time payments* are single transactions for specific services. *Consulting and implementation fees* generate income through expertise or service deployment. Some startups operate under a *non-profit model*, focusing on creating value without direct profit, often relying on grants, donations, or other funding sources to sustain their activities. The largest group comprises startups with *undisclosed* revenue models, accounting for 39 startups.

5. Discussion

Understanding the business models of GovTech startups is key to driving the modernization of the public sector in an increasingly complex and technology-driven era. GovTech ecosystems have emerged as disruptive forces, with startups tackling critical public challenges such as administrative inefficiencies, regulatory complexity, and citizen engagement (Bharosa, 2022; Mergel et al., 2022). Despite their transformative potential, governments often face significant barriers to adopting these innovations due to strict procurement processes, complex legal frameworks, and an overall reluctance to embrace novel business models (Filer, 2019; OECD, 2019). However, countries like Germany, which boasts a rapidly growing GovTech market, show how customized digital solutions can effectively meet specific governmental needs. This highlights the importance of matching technological capabilities with the unique requirements of public institutions (Stuck & Dieke, 2023).

Our taxonomy provides a systematic framework for understanding how digital technology is implemented in various aspects of GovTech startup business models. By synthesizing research findings with empirical observations, the taxonomy reduces the complexity of the GovTech landscape and offers a clear, structured overview (Nickerson et al., 2013). Within the frame of business models, it articulates how startups can leverage digital technologies across three key dimensions: value proposition, value creation and delivery, and value capture (Wirtz et al., 2016).

For the dimension of *value proposition*, our research reveals that in the *solution domain,* 25 startups focus on *citizen services*, making it the most prominent domain in the GovTech landscape. These startups aim to improve citizen communication, enhance access to digital public services, and offer personalized solutions. For instance, *TaxFix*

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

simplifies tax returns, making the process faster, more accessible, and user-friendly. Similarly, *FixMyCity* enables citizens to report urban issues, such as potholes or broken streetlights, directly to local governments, fostering more efficient resolution mechanisms. Solutions targeting *internal administration* and *smart urban infrastructure* follow closely, with 18 startups each addressing these domains. For example, *GovRadar* streamlines public procurement through AI-powered vendor matching, while *Smart City Systems* optimizes urban infrastructure with automated parking management systems. This distribution reflects a dual intent: startups aim to enhance citizen-centric service delivery while governments seek to improve operational efficiency and engagement. Conversely, sectors like *defence and security*, as well as *health and social services* remain underrepresented, likely due to their heightened organizational complexity and reliance on sensitive data. These underrepresented areas underscore the need for targeted initiatives to reduce barriers to innovation and broaden GovTech's scope in addressing public-sector challenges (Bharosa & Janowski, 2024).

Value creation and delivery is substantially characterised by their key technologies, openness, and the degree of public sector integration in their business models. Among the 85 startups analysed, 33 employ a basic technology stack as *key technology,* such as simple web applications, rather than advanced innovations like AI or blockchain. This reliance points to persistent gaps in the public sector's digital infrastructure, where foundational technological needs remain unmet (Dener et al., 2021). Consequently, startups prioritize addressing these deficiencies to create immediate value. For instance, *Vilisto* offers straightforward scheduling software to help local governments manage resources more effectively, bridging critical operational gaps (Stuck & Dieke, 2023). These findings emphasize the urgent need for public administrations to invest in digital infrastructure and workforce training, creating a supportive environment where advanced technologies can flourish. A stepwise, incremental approach to technological transformation appears more feasible in the short term, allowing governments to address fundamental needs before adopting more complex innovations.

Another noteworthy finding is the limited *openness* of GovTech startup business models with the dominance of proprietary solutions. A clear majority of startups (70) offer proprietary solutions, with only nine startups applying open-source principles and four utilizing open data. An example of a startup with an open-source approach is *HeiDi*, which develops open-source municipal tools, enabling cost-efficient customization of digital services for local governments. *Geospin*, on the other hand, leverages open geodata alongside proprietary datasets to provide predictive analytics and geospatial insights for smarter urban planning and optimized business decisions. The overwhelming reliance on proprietary software highlights a missed opportunity for fostering openness and reducing vendor dependency. Governments must actively promote the development and procurement of open-source solutions to foster competition, enhance transparency, and build internal expertise (Yoshida & Thammetar, 2021). By encouraging the use of open-source technologies, public institutions could strengthen their resilience, reduce long-term costs, and establish a more diverse and competitive market ecosystem.

Public sector integration influences the success and adaptability of GovTech startups by affecting the alignment of their business models with government systems. Startups with high integration, such as *Vialytics*, which works with over 200 municipalities on AI-powered road maintenance, demonstrate the viability of deeply integrated models. These startups often adopt co-creation-based business models and work closely with public agencies to deliver *customized solutions* for specific needs such as administrative efficiency or infrastructure management (Bharosa, 2022; Stuck & Dieke, 2023). By embedding their services in public authority workflows, these startups ensure higher adoption rates and sustainable value creation, establishing themselves as indispensable partners. By contrast, *independent* startups with lower integration offer generic solutions such as web applications. While these solutions address immediate needs, their limited integration limits their systemic impact and long-term scalability (Mergel et al., 2022). Barriers to greater integration, such as rigid procurement processes, outdated IT systems, and cultural resistance, have direct implications for GovTech business models. Startups that focus on open innovation ecosystems and use open-source models could reduce these barriers by promoting adaptability and cost efficiency (Yoshida & Thammetar, 2021). In addition, startups can rely on platform-based models that enable modular integration and allow for a phased roll-out without overhauling existing systems. This highlights the need for business models that can be adapted to different levels of public sector readiness. Ultimately, prioritizing a public sector integration not only improves the alignment of startup solutions with public sector needs but also ensures the scalability, resilience, and broader adoption of public sector innovation.

For *value capture*, our results underscore the crucial role of *funding sources* in shaping the GovTech landscape. Of the startups that disclosed their funding, 28 rely on *private capital*, while only 13 startups benefit from *public funding*. GovTech startups often rely on venture capital funding, which can clash with the slower, fragmented nature of public procurement, limiting their scalability and growth (Mergel et al., 2022). This limited public investment reflects a missed opportunity to strategically support startups that address pressing government challenges. Scaling up public funding programs could significantly accelerate the growth of the GovTech sector and ensure that startups with tailored solutions receive the resources they need. Aligning public funding with modernization goals would also improve the sector's ability to deliver sustainable innovation.

Limitations

We must acknowledge two limitations of this study. First, taxonomies are inherently iterative and cannot claim to be complete or final (Nickerson et al., 2013). In developing our taxonomy, we specifically focused on the characteristics of business models that distinguish GovTech startups in Germany. While this approach ensures the clarity and relevance of the taxonomy, it may exclude certain characteristics that could be relevant in other geographic or regulatory contexts. This trade-off was made to strike a balance between comprehensiveness and parsimony, ensuring that the taxonomy remains both actionable and understandable for the target audience.

Secondly, our empirical data is mainly drawn from publicly available information on 85 GovTech start-ups in Germany, supplemented by secondary sources such as Crunchbase. While this approach provides a solid foundation, the sample is inherently skewed towards start-up business models and may not fully capture the strategies of larger, more established technology providers or innovations originating from the public sector. Nevertheless, the iterative process of taxonomy development mitigates this limitation by integrating conceptual insights from the literature to ensure broader applicability. Given the central role of start-ups as drivers of innovation in the GovTech sector (Bharosa, 2022). the taxonomy remains a valuable tool for researchers and practitioners seeking to promote digital transformation in public administration.

Practical Implications

First, the taxonomy of GovTech startup business models presented in this study equips public administrators, startup founders, and policymakers with a robust framework to navigate the complexities of GovTech ecosystems. Specifically, it allows stakeholders to identify strategic opportunities and challenges across the value proposition, value creation and delivery, as well as the value capture dimensions. For example, public sector organizations can utilize the taxonomy to prioritize engagement with startups offering tailored solutions for more citizen-centred services or operational efficiency, as these domains demonstrate significant potential for value creation. Simultaneously, startup founders can adopt the taxonomy to align their offerings with the needs of public institutions, improving the scalability and adoption of their innovative solutions. This structured approach supports both proactive planning and reactive decision-making, enabling more resilient and adaptive public sector modernization.

Second, our taxonomy highlights the necessity of fostering partnerships and open innovation practices to overcome systemic barriers such as procurement inefficiencies and rigid regulatory frameworks. Public administrators are encouraged to explore collaborations with startups that embrace open data and open-source technologies, reducing vendor dependency and promoting adaptability. Similarly, GovTech startups can leverage the taxonomy to refine their strategies for public sector integration, ensuring their solutions are not only innovative but also practical and implementable within government systems. By bridging the gap between technological capabilities and public sector readiness, the taxonomy facilitates a co-creative ecosystem conducive to sustained innovation and efficiency.

Theoretical Implications

The taxonomy extends existing literature on digital transformation in the public sector by introducing a structured framework that emphasizes the interplay between technological innovation and public sector constraints. Unlike prior studies that focused predominantly on technological capabilities or ecosystem dynamics, this research provides a granular analysis of business model components tailored to GovTech startups. It contributes to the understanding of how value proposition, value creation and delivery, and value capture dimensions are interrelated and how these interrelations drive innovation in regulated environments. This framework enriches theoretical discussions on digital government by offering new perspectives on how startups navigate and mitigate the unique challenges of public sector ecosystems.

Furthermore, the study advances business model theory by illustrating how contextual factors such as regulatory complexity, public funding dynamics, and citizen-centric goals shape the design and evolution of business models in the GovTech sector. By integrating empirical data with theoretical constructs, the taxonomy offers a foundation for comparative analyses across different domains and geographies, shedding light on the universal and context-specific characteristics of GovTech startup business models. This theoretical contribution not only fills a critical gap in the literature but also opens new avenues for interdisciplinary research on public-private innovation in digital government.

Future Research

Our taxonomy provides a foundation for studying transitional pathways between different GovTech business models. Future research could investigate how startups evolve their business models in response to changes in regulatory environments, technological advancements, or public sector demands. For instance, analysing the

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

transition from proprietary to open-source models or from independent solutions to fully integrated public sector systems could shed light on the antecedents and enablers of successful GovTech scaling. Such research could also examine how specific dimensions of the taxonomy, such as public sector integration or funding sources, influence the scalability and sustainability of GovTech innovations.

Another promising avenue for future research lies in exploring the performance implications of different business model designs within the GovTech sector. By leveraging the taxonomy as a coding scheme or survey instrument, scholars can compare the economic, social, and operational outcomes of various GovTech models. For instance, researchers could analyse whether startups focusing on citizen engagement outperform those targeting operational efficiency in terms of public value creation or long-term adoption. These insights could help refine the taxonomy further and provide actionable guidance for both academics and practitioners seeking to optimize GovTech innovations.

6. Conclusion

The growing importance of GovTech startups highlights their critical role in driving digital transformation in public administration, addressing complex challenges such as regulatory constraints, operational inefficiencies, and citizen engagement. This study aimed to systematically explore the business models of these startups, providing clarity on how they align technological innovation with the unique needs of the public sector. By developing a taxonomy structured around value proposition, value creation and delivery, and value capture, we offer a comprehensive framework that classifies and analyses diverse approaches within the GovTech sector. The findings underscore the importance of tailoring business models to overcome public sector constraints while leveraging opportunities for co-creation and innovation. Moreover, our taxonomy advances theoretical understanding of business models in regulated environments and offers practical guidance for fostering collaboration between startups and public institutions. In doing so, it equips stakeholders with actionable insights for fostering innovation and modernizing public services, ultimately contributing to a more agile and responsive public sector.

Abstract. Governments depend on procurement to help them achieve their digital transformation goals. Historically, public sector technology contracts have overwhelmingly flowed to large technology firms. However, governments have begun to explore opening up the procurement process to GovTech startups to drive innovation. Yet, this policy goal has proved challenging to implement. This paper explores why this is the case by presenting the case study of GovTech startup procurement in the United Kingdom. By focusing on the role of temporal dynamics in shaping procurement processes and drawing on 32 primary interviews with stakeholders across the UK GovTech ecosystem and supplementary archival data, this study identifies how the financial, staffing, and strategic processes within public sector bureaucracies enact an erratic and unpredictable procurement rhythm. It further demonstrates the challenges startups face when encountering this rhythm, struggling to predict or synchronise with it. Startups who are successful face new challenges from managing multiple rhythms. While conventional discourse often frames this procurement challenge as a mismatch between the "slow" public sector and "fast" startups, this paper instead reveals the complex and contradictory rhythms that frustrate GovTech procurement.

Keywords. GovTech, Public Procurement, Temporality, Digital Government, Startups.

1. Introduction

Policymakers understand that digitalisation is a key component of building a strong and effective public sector. As a result, governments around the world are racing to digitalise their often crumbling, outdated, and legacy information systems. Getting this right requires key decision-makers to navigate an increasingly complex environment defined by rapid technological innovation and change. As most governments are likely to lack the necessary internal capabilities to build and innovate state-of-the-art technological solutions, procurement serves as a key mechanism of digitalisation. While many governments have experience procuring technology from large "primes" (Margetts & Dunleavy, 2024), there is a growing interest in opening the procurement process to the broader "GovTech" ecosystem. As defined in the European Interoperability Act, GovTech "means technology-based cooperation between public and private sector actors supporting public sector digital transformation" (EU, 2024, Article 2). The same act provides specific provisions dedicated to "facilitating the development of an open European GovTech ecosystem, including cooperation with SMEs, research and educational institutions, and start-ups" (EU, 2024, Article 11). The potential, according to a recent World Economic Forum article, is large, with the GovTech industry representing a "$9.8 Trillion Opportunity" (World Economic Forum, 2025). Yet, despite the

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

importance ascribed to GovTech and its potential to drive governmental innovation, governments face challenges in realising this potential (Bharosa & Janowski, 2024). In particular, they have struggled to maximise procurement from small GovTech providers (Bharosa, 2022; Filer, 2019; Mergel et al., 2022; Taylor & Viner, 2021).

This dichotomy represents a clear opportunity for academic research. Interestingly, despite recommendations to focus on the role of procurement in GovTech innovation (Bharosa, 2022; Hoekstra et al., 2023), there is still a general lack of empirical studies exploring how procurement practices are preventing GovTech suppliers from working with the public sector. Although GovTech innovation does not necessitate a specific type of supplier, startups, as a specific type of small and medium-sized enterprise (SME), are often the particular focus of attention. Unlike larger and more established technology primes, GovTech startups are viewed as more innovative due to their ability to work in an agile fashion, rapid prototyping, and lower costs (OECD, 2024). Notwithstanding some vital public policy reports (Filer, 2018, 2019), and some pioneering early studies (De Coninck et al., 2018; Hoekstra et al., 2023), more empirical work is needed to understand how GovTech startups interact with other suppliers, investors, buyers, and intermediaries in governmental procurement processes.

This paper represents an initial attempt at providing empirical evidence on the barriers that impact the involvement of GovTech startups and SMEs in governmental procurement processes. To do this, the paper focuses on a single case study: the United Kingdom's GovTech ecosystem. The UK case is interesting in that the country has long understood the importance of procurement for digitalisation and it has faced several scandals involving procurements from large technology firms. However, despite its pronouncements to increase procurement from GovTech startups and SMEs, it has had limited success to date (British Chamber of Commerce, 2024; Cabinet Office, 2020).

In the UK, efforts at fostering innovation through public sector digitalisation have often been criticised for being too slow. Increased collaboration with startups is presented as having the ability to help the public sector speed up. This context was well articulated during a 2017 meeting at the House of Lords Select Committee on Artificial Intelligence, when Matt Hancock—then Secretary of State for Digital, Culture, Media and Sport—was questioned on the NHS's "very slow" record of innovation and the "GovTech Catalyst" scheme, a programme designed to harness startup innovation to solve challenges across government. Hancock responded, "Most of GovTech is about procurement […] Getting procurement rules right is one of the most important parts of driving improvements in technology through government" (House of Lords, 2017). However, while GovTech startups may move fast, the assumed slowness of government processes is often seen as a fundamental barrier to increasing procurement from startups, with time-consuming procedures and slow sales cycles. In surveys of UK and US public-sector-facing startups, 61% of respondents identified procurement as their most significant barrier, calling out its "time-consuming" procedures (Taylor & Viner, 2021, p. 25) and the time taken to secure government contracts (Orazem et al., 2017). In a sector where "innovation" equals "competitive advantage", companies whose products "have a nine-month 'shelf life' before the competition catches up […] fear their technology will be obsolete" by the time the government resolves its decision (ibid.). The notion of "speed", with government assumed to be "slow", and startups "fast", can be observed across government policy documents, academic literature, and the broader grey literature. This appears to suggest the importance of temporal dynamics in governmental procurement processes. Yet, these "mismatched time frames" (Filer, 2019) remain un-theorised and empirically untested in Digital Government and Procurement scholarship. Thus, this paper asks the question: How is public procurement from GovTech startups complicated by temporal dynamics? While procurement challenges relating to time (e.g. payment timelines) have been noted in previous scholarship (Loader, 2013), a more comprehensive investigation of temporal dynamics leveraging more recent advances from wider management research has not yet been conducted. Such research emphasises that surface-level issues such as slow processes or payment timelines may stem from underlying dynamics in the (mis)alignment of rhythms of organisational processes.

Methodologically, the paper relies on evidence gathered from 32 primary interviews conducted with multiple stakeholder groups across the UK, as well as supplementary archival documents. Drawing on this empirical material, the research explores the barriers that are impeding the UK's efforts to procure from GovTech startups. As a result of this research, this paper makes several contributions. It addresses the need for research on public procurement barriers to GovTech start-ups and provides empirical evidence to show that temporal dynamics play an important role. Examining these temporal dynamics in depth, the paper offers novel theoretical contributions that show how Public Sector Buyers' (PSBs) organisational processes enact an erratic and unpredictable procurement rhythm that is both too slow and too rushed for startup suppliers to engage with effectively. Startup suppliers encountering this procurement rhythm face a sequence of challenges – predicting, synchronising, and managing the rhythms of multiple internal and external processes. Thus, the paper challenges the dominant, simplified understanding that GovTech procurement issues can be ascribed to a simple clash of 'slow' bureaucracies and 'fast' startups, pointing instead to the complex temporality that arises when different organisational forms interact. Overall, the findings broaden our understanding of procurement barriers, contextualising systemic constraints and conflicting policy objectives as part of organisational processes and conflicting rhythms.

2. Theoretical Background

In an attempt to overcome the failings that accompanied earlier New Public Management approaches to digital transformation, many governments have embarked on a "comprehensive public administration reform agenda" (Boots et al., 2024, p. 300). This transformation has been a gradual process, manifesting in several waves (Dunleavy & Margetts, 2006b, 2006a; Margetts & Dunleavy, 2013, 2024). The most recent wave has been associated with calls for improved state capacity, particularly when it comes to digital technologies and data analytic capabilities (Mazzucato & Kattel, 2020). As the public sector is still often believed to have fallen behind technologically (Clarke, 2020; Clarke & Margetts, 2014; Dunleavy & Margetts, 2006a), governments have sought to modernise their approach to IT procurement: making contracts smaller and shorter (particularly for software), building more in-house expertise, buying from varied supplier sizes, and choosing open-source solutions (Boots et al., 2024). Though procurement plays a critical role in most governmental digital transformation initiatives, and there is substantial research on the procurement of technology and procurement of research, its role in Digital Government is often surprisingly "overlooked" (Boots et al., 2024, p. 297). This is unfortunate, as the history of digital transformation can only be understood in relation to procurement practices. However, recent research is now beginning to pay specific attention to how governments can better procure important emerging technologies, such as Cloud Computing (Jones, 2015) or Artificial Intelligence (McBride et al., 2021; Sanchez-Graells, 2024), as well as the role of new technologies in E-Procurement processes (Chen et al., 2021).

Focus has also begun to move beyond exploring the procurement of specific technologies necessary for digitalisation, looking into the broader procurement ecosystem and how the procurement process itself could be innovated upon (Boots et al., 2024; House of Lords Defence Committee, 2023). Of particular note, many policymakers have started to look to 'GovTech' as a means of improving their digital capabilities. It is argued that collaborating and procuring from GovTech startups would help to reduce dependence on legacy IT suppliers, support local firms to stimulate growth, and increase innovation in the public sector (Bharosa, 2022). Governments worldwide have implemented new measures to foster GovTech ecosystems that they can procure from (Hoekstra et al., 2022). However, progress has been slower and patchier than expected (Taylor & Viner, 2021), with procurement from startups hindered by barriers (Bharosa, 2022; Filer, 2019; Hoekstra et al., 2023). Existing work into why this is the case has predominantly focused on the technical barriers—such as interoperability and data security—inhibiting procurement from startups. These explanations are insufficient (Barcevičius et al., 2019). However, one potentially interesting dimension of barriers, which remains underexplored in the literature, is temporality. In their exploratory case study of GovTech ecosystems in the Netherlands and Lithuania, Hoekstra et al. reference the potential role of temporal dynamics as one of the barriers, highlighting that the pace of the private sector is perceived as "too slow for a startup or scale-up" (Hoekstra et al., 2023, p. 283). This barrier merits a more systematic exploration.

While theories of time and temporality are often discussed in management research, there is significantly less usage of this work in digital government studies. In management research, temporality continues to become a well-established "research lens" (D. G. Ancona et al., 2001; Blagoev et al., 2023), as more and more management scholars have found their focal phenomena – such as organisational change, conflict, identity, and strategy – to be underpinned by actors' subjective experience of speeds, rhythms, and time horizons. Digital government research can now leverage and apply these theoretical advancements. For scholars of digital government, several temporal contributions are especially relevant. First, cultural practices within organisations shape how individuals experience and conceptualise time (Orlikowski & Yates, 2002). Second, the stories actors tell can shape temporal norms, determining if, when, and how an organisation might decide to act (Wood et al., 2021). This enables and precludes strategic possibilities (Kaplan & Orlikowski, 2013). Third, multiple rhythms and tempos exist within and across organisations (D. Ancona & Chong, 1996; Bluedorn, 2002). Fourth, when organisations with different temporal dynamics "collide", this can cause tensions (Reinecke & Ansari, 2015). Finally, organisations can "adjust the pace or cycle of [one] activity to that of another" (D. Ancona & Chong, 1996, p. 253) as they try to synchronise to dominant cycles (Pérez-Nordtvedt et al., 2008; Sandra et al., 2023). However, synchronising to one cycle can lead to misalignment with others, creating new conflicts (Bluedorn, 2002). Given that Digital Government discourse is often framed as a way to speed up "slow bureaucratic machines" (Bharosa, 2022, p. 4)", and that GovTech ecosystems involve multiple types of organisations interacting, Digital Government scholars could likely benefit from existing theoretical tools for analysing organisational rhythms, processes, and interactions.

3. Research Methods

3.1 Research Design

Following Yin's single case-study approach, this paper looks at the UK GovTech ecosystem as the 'unit of analysis' (Yin, 2013, p. 31). The UK GovTech ecosystem comprises diverse stakeholders such as Public Sector Buyers (PSBs) in central government, local government, and healthcare; suppliers, including large incumbent suppliers, startups, and investors; and intermediaries, such as consultants and lawyers. Collectively, these organisations constitute an organisational field (DiMaggio & Powell, 1983), shaping institutional norms, practices, and procurement dynamics

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

within GovTech innovation. This ecosystem constitutes a revelatory case (Eisenhardt & Graebner, 2007) for understanding GovTech procurement dynamics for five reasons. (1) The UK is heralded as a global leader in many international digital government rankings (OECD, 2019). (2) Its public sector relies heavily on procurement (NAO, 2011, 2025); (3) but has been criticised for its reliance on large technology providers (Bracken, 2020; Greenway, 2020). (4) It has implemented a series of programmes and policy postures to promote innovation and diversity in technology procurement (e.g. GovTech Catalyst, Spark). (5) These attempts have had limited success (Science and Technology Committee - House of Commons, 2019). These factors mean that stakeholders acutely understand both the drivers and barriers to increased procurement from startups, rendering it particularly susceptible to this study.

The UK government spends an estimated £14 billion on digital programmes and technology annually (NAO, 2025). Historically, attempts at transforming UK digital government have been linked to procurement reforms, with the creation of the Government Digital Service (GDS) in 2011 linked in part to numerous expensive technology contracting failures. To counteract these failures, GDS enacted several reforms: developing spend controls and digital service standards, simplifying information classification levels, and building internal digital capabilities across government (Clarke, 2020). The following year, procurement procedures were streamlined with the introduction of G-Cloud, which enabled companies to list their offerings without a full tender or competition process (Science and Technology Committee - House of Commons, 2019, p. 51). The goal of this reform was, in part, to reduce costs and increase innovation by including more SMEs and startups. At the beginning, GDS's reforms did have success in diversifying procurement spending, with the market share of the top ten ICT suppliers falling from 53% to 39% (Kotecha & Desmond, 2017, p. 5). However, startups (as opposed to all SMEs) still only won less than 3% of government procurement spending between 2012 and 2014 (Spend Network, 2015). In 2018, a new "GovTech Catalyst" fund was created and provided £20 million to support the procurement of innovative solutions to several 'public sector challenges' from GovTech startups. However, Select Committee evidence from a roundtable of startups suggested that the programme was undermined by insufficient funding and cumbersome processes (Science and Technology Committee - House of Commons, 2019, p. 54). The new Labour government that came into power in 2024 has made reforming procurement, and increasing GovTech startup procurement in particular, an explicit policy goal.

3.2 Data Collection

Collecting and engaging with archival data provided foundational context. It informed our sampling strategy and helped interpret the primary data, which consisted of 32 expert interviews conducted between May and July 2024, each lasting approximately one hour. Participants were selected using purposive sampling based on their experience in the UK GovTech ecosystem. We identified potential interviewees—across public sector organisations, startups, investment bodies, and intermediary roles—by reviewing grey literature, government websites, and relevant programme listings. Given the difficulty of accessing senior decision-makers, we also employed convenience and snowball sampling. According to the inclusion criteria, all participants had direct or indirect experience with public procurement. While we considered providing further detail on participants' roles, we avoided role-specific identifiers due to the risk of de-anonymisation in a small and interconnected ecosystem. Participants are categorised by stakeholder type, and the sample reflects a wide range of seniority and sectoral experience (see Table 1).

As the final column shows, many participants had additional experience in other stakeholder groups that informed their experiences. For example, many investors had experience in startups and many GovTech founders had experience in government. The sample likely skews towards those already interested in procurement reform and those who agreed to be interviewed may be further self-selecting, biasing towards an extreme (Collier & Mahoney, 1996). However, the research design was oriented towards an "information-oriented selection," prioritising information richness over representativeness (Flyvbjerg, 2006).

Tab. 1 – Participant Sample

Stakeholder Type	Stakeholder Group	# Participants currently in group	#Additional Participants with experience in group
PSB	Civil Servant	2	10
	Government Advisor	1	0
	Procurement Official	1	1
		4	
Mediator	E-Procurement Startup	3	0
	Lawyers	2	1
	Procurement Consultants	3	1
		8	
Supplier	Startup	9	6
	Digital Consultants	3	9
	Large Corporates	1	2
		13	
Investors		**7**	2
Experts		**3**	1
TOTAL		**32**	

A semi-structured interview approach was employed, with protocols tailored to each stakeholder group (see Appendix), enabling flexible responses to new information. Interviews focused on procurement experiences, challenges, and organisational processes, encouraging detailed accounts of recent cases (e.g., tendering, bidding, investing). Temporal dynamics were explored indirectly through follow-up questions when raised organically, to reduce priming and social desirability bias.

3.3 Data Analysis

Data analysis took place concurrently with data collection, ensuring that emerging insights informed subsequent interviews. All interviews were recorded and transcribed, and an initial round of open coding (Gioia et al., 2013) was conducted by MAXQDA. Initial coding rounds produced 658 codes, many of which related to systemic constraints in GovTech procurement for both Public Sector Buyer (PSB) and startup supplier barriers. A breakthrough moment came in one of the earliest interviews when a startup lobbyist remarked: "With procurement, the number one issue, along with speed and stuff—it's not actually the rules that are the problem, it's the interpretation of the rules… they interpret rules in a really conservative way and sort of fuck over startups that way" (P1). This offhand reference to "speed and stuff" might appear insignificant at first. However, as more interviews were conducted, similar temporal analysis emerged, with participants discussing the "speeds", "rhythms", "cadences", and "cycles" of GovTech procurement. Recognising the significance of temporality, subsequent rounds of analysis linked first-order constructs into both systemic constraints and rhythms, together constituting organisational processes that were related to finance, staffing, or strategy (Table 2).

Tab. 2 –Example Data Structure: PSB Organisational Processes

Category	Theme	Codes	Exemplar Quote
PSB Organisational Processes: Financial	Shrinking Budgets	Economic Climate	*"The macroeconomic trend of government having less and less money to go around" (P6)*
		Budgetary Pressures	*"as always, there are budgetary pressures, you want the middle manager to say, no, this is indispensable" (P17)*
	Financial Rhythm	Spending Reviews	*"[Annual] Spending Reviews […] make it very difficult for you to commit to contracts that run beyond twelve months"* (P7)
		Financial Year	*"It's to do with budget allocations in a year. Departments are held accountable for going over budgets, but they're also held accountable for going under budget. So as you get towards the end of the financial year there's lots of scrapping around" (P8)*
PSB Organisational Processes: Staffing	Lacking Knowledge	Information Asymmetry	*"Not knowing what's out there in the market" (P4)*
		Technology Knowledge Gaps	*"Technology feels like a bit of an outlier" (P7)*
		Ignorant of Startups	*"So, in terms of a lack of understanding or empathy, I think I think there is that barrier there; to be honest, a lot of civil servants have only been in the civil service. They've never seen it from the startup perspective" (P26)*
	Staffing Rhythm	Churn	*"Churn happens because the mechanics of the system aren't set up to allow continuity of longer than a year"* (P5)
		Losing Institutional Knowledge	*"You've just got to know startups, and now you're gone" (P3)*
PSB Organisational Processes: Strategy	Avoiding Failure	Bigger as Safer	*"Nobody is gonna give you a prize for excluding G4S" (P24)*
		Fearing legal challenge	*"So, all these things are driven by, if you like risk that arrives from the rights of any supplier to claim that public sector buying decision over 140 grand has been distorted in some way." (P12)*
		Avoiding Media	*"If you waste a bit of money in failure, you will have to explain that to the public. If you wasted a lot of many on shit programs, that slow shitness doesn't get in the news" (P16)*
		Misaligned Incentives	*"It' s not that the individuals are shit but they're not incentivised to…do anything better. Their incentive is to find something safe*" (P5).
	Strategy Rhythm	Short-termism	*" I don't commit to a very long procurement" (P27)*
		Disjointedness	"*Current procurement processes are like a poor relay race" (P18)*

Subsequent rounds of axial coding (Strauss & Corbin, 1990) identified the processes connecting these categories, surfacing how PSB organisational processes enacted the procurement process rhythm and how startup organisational processes determined how they encountered this rhythm (Figure 1). This allowed us to connect otherwise distinct systemic constraints, verifying that temporal dynamics were an important explanatory factor.

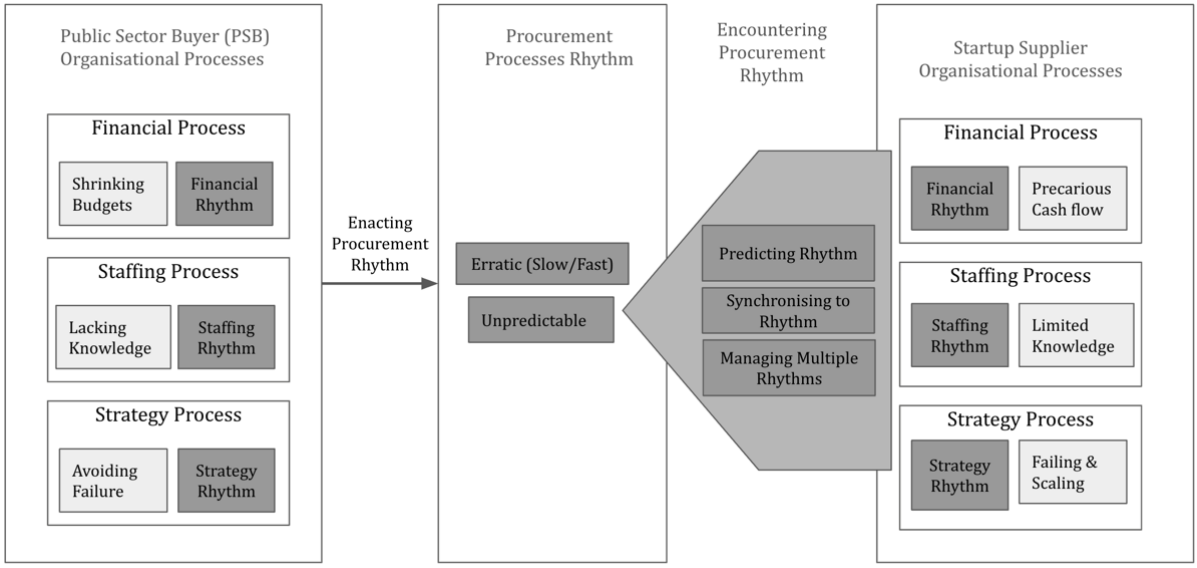

Fig. 1 – Data Structure of Axial Coding Categories and Themes

4. Results

From the interviews, participants with experience in both PSBs and startups described their organisation's systemic constraints that prevented increased procurement from startups. In both types of organisations, participants described constraints relating to financing, staffing, and strategic goals. Our analysis helps explain these experienced procurement challenges by pointing to the temporality of their underlying organisational processes. As the following results section will demonstrate, throughout each of these processes, distinct rhythms compound and exacerbate systemic constraints in GovTech procurement.

4.1 Organisational Processes of Public Sector Buyers (PSBs)

Financial Processes: Participants discussed the challenges of limited and often decreasing budgets (P5, 6, 9, 13, 17, 25). Limited budgets encourage buyers to focus more on cost and less on innovation. Across the public sector, there is "*the macroeconomic trend of government having less and less money to go around*" (P6), creating "*budgetary pressures*" (P17). These constraints are acutely felt by local government (P6, 9, 13). Two interviewees highlighted the trend of many councils declaring bankruptcy (P6, 25), despite the "*risk-averse*" and "*tightly controlling*" policies of procurement officials (P25). Other participants challenged the public narrative of shrinking budgets, offering examples of considerable funding that was allocated to local government. However, in these examples, the funding either had to be returned to the central government when it expired, or startups were late to hear about it (P9, 20).

Temporal dynamics help explain these financial processes. Across government, the financial rhythms of budgets exacerbate challenges for GovTech procurement. Many civil servants raised that the combination of Treasury Accounting and the recent succession of annual spending reviews led to a pattern in the fiscal year of hesitant spending in the first half and a "*rush to march*" in the latter half, to avoid underspending (P8, 13, 20). These budget cycles had further impacts on both staffing and strategy processes.

Staffing Processes: PSBs lack knowledge about technology and startups (P8, 16, 26, 24). As one former civil servant reflected, "*within the procurement service…additional technology feels like a bit of an outlier*" (P28). Another described the daily routine of their colleagues as "*procuring pens in the morning and scooters in the afternoon*" (P24). As such, there is little specialist knowledge regarding technology within many commercial functions. Participants acknowledged that this was slowly changing and there were highly skilled individuals (P17, 25). However, buyers with technological skills were described as "*peripheral figures*" who often struggled to "*properly embed new technology*" (P17).

This systemic constraint can only be understood in relation to the compounding rhythms within PSBs. Under-resourced and under-skilled PSBs are further undermined by the nature of budget cycles, which contributes to high churn in the lower levels of the civil service. Consequently, startup suppliers described how buyers "*always changed*" (P1). An ex-civil servant frustratedly explained, "*Churn happens because the mechanics of the system aren't set up to allow continuity of even longer than a year…this is a very big problem*" (P27). Others reiterated that even in public sector organisations that were explicitly focused on startups and innovation, high churn had

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

detrimental effects on knowledge (P16).

Strategy Processes: PSBs are, understandably, risk-focused; particularly given the high stakes involved in many procurement decisions (P8). Legal constraints are designed to mitigate risks: of being sued, of malfunctioning technology, or of suppliers going bust. Other goals, such as avoiding public failure and media attention, create further constraints that prevent collaboration with startups (P14, 27). One participant with experience in large-scale health technology procurement characterised the risk position as "*extremist*". He continued, "*this survival mode" is "the total opposite of a transformation program", which ought to "throw it up in the air and make change happen*" (P27). Participants tended to agree that the strategic process was undermined by misaligned incentives (P5, 11, 12, 13, 14, 16, 18).

These persistent challenges are easier to understand when situated in the context of the 'Strategy Rhythm'—the temporal dynamics that underpin decision-making and goal setting. The siloing of teams creates a disjointed working rhythm, undermining the ability for joined-up thinking. Throughout the interviews, participants used verbs that imply a lack of intention or even carelessness, such as "*lobbing*" and "*chucking*" (P5, 13, 18). Reflected on their time in a PSB, one participant explained that performance management does not facilitate "*the next person down the chain to actually add value*" (P18). Another with similar experience offered a memorable metaphor—procurement processes as a "*relay race*", where each actor focuses on working as quickly as possible without considering the handover between different stages of the procurement process (P18). Budget cycles further undermine attempts at implementing strategic processes. One civil servant remarked that a budget "*is not a real budget*" because it must be agreed by the department annually. He continued, "*I don't commit to a very long procurement, and I don't necessarily get value because I don't know if I've got the money in year two, three, and four. And this is bad for public sector value*" (P27).

4.2 PSBs Enacting Procurement Process Rhythm

Our results further demonstrate how PSBs' interrelated organisational processes are enacted in the temporal dynamics of the procurement process itself (Figure 2). This process is erratic, both too rushed and too slow, and unpredictable.

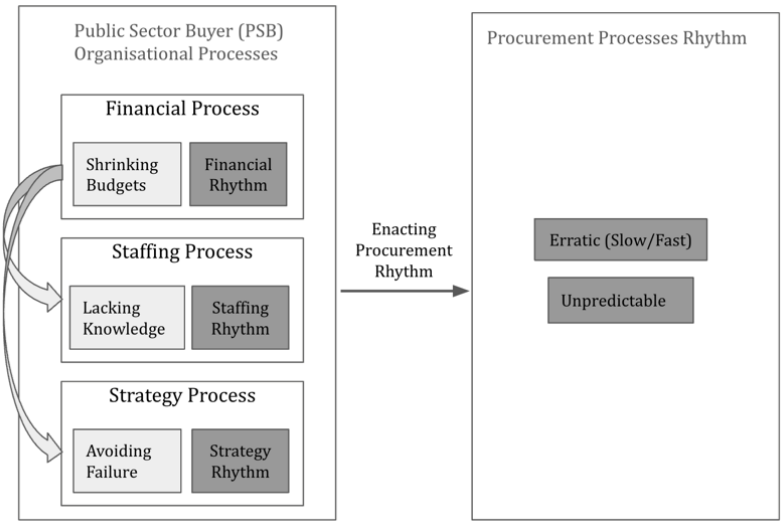

Fig. 2 – PSB Organisational Processes Enacting Procurement Rhythm

Erratic (rushed): PSBs often rush through improper pre-market engagement. Participants described how commercial teams focus on the contracting phase of procurement (P18, 25, 27, 32). An experienced buyer described how "*all the efforts go into the procurement phase. They really should go into the pre-procurement phase, the dialogue phase, the signal-to-market phase…The procurement, by the time you get there, should be the least intense part of the process*" (P27). Pre-market engagement is particularly important for suppliers who are less likely to have established connections with the public sector. Hurried pre-procurement and post-procurement phases reflect a broader phenomenon of rushed processes. Commercial teams rush to address expiring contracts and issue "*irregular contract extensions*" (P2). Local councils discover available project funding at the last minute and rush to meet deadlines (P9, 20). Civil servants acknowledged the increased use of frameworks (closed groups of pre-approved suppliers) because in many cases, "*there simply isn't the time*" to run formal procurements (P8). While frameworks are not inherently problematic, their current usage disadvantages smaller suppliers. Finally, buyers and suppliers alike discussed the impact of the financial year (P5, 13, 20). Buyers described a "*flurry to purchasing*", causing a "*mad scramble*" (P8). Likewise, suppliers described the "*frantic*" and "*crazy deadlines*" (P20).

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Erratic (slow): At other points, procurement rhythms were described as too slow by all types of stakeholders (P16, 26, 27, 31). Formal procurement processes, unlike direct awards, can take "*six to eight months*" (P13) with multiple "*different hoops*" for suppliers (P20). Involving multiple departments or teams can slow things down (P12, 20, 26). One local authority supplier described the "*luck*" necessary to have the "*right stakeholders*" simultaneously aligned, particularly during holiday periods (P20). "*Little redundancy*" means that "*when things don't go to plan, there are delays everywhere*" (P24). Another startup similarly described how overworked staff members in local authorities realised they had holiday to take at the end of the fiscal year when extra staffing was needed to meet rushed deadlines, with conflicting financial and staffing rhythms further slowing procurement processes (P20). Corroborating existing research, the slow sales cycle was a repeated feature of interviews (P8, 9, 16, 17, 21, 31).

Unpredictable: This erratic rhythm—lurching between slow and rushed—combined with an opaque procurement process makes the process hard to predict (P24). While suppliers could anticipate some patterns in government sales cycles—for example, noting more tenders during summer and winter holidays (P2, 4, 8, 15)—in other ways, the procurement process was much harder to predict. One senior civil servant acknowledged this, describing, perhaps hyperbolically, that procurement was "*an uncertain process that could take three months or three years*" (P8). This uncertainty was exaggerated by political cycles, with suppliers "*relying on cash for the next couple of years of work*" that "*could evaporate*" with a General Election (P8). Another senior civil servant with experience in startups and investing described a broader, cultural "*tension*" between suppliers and buyers, who "*operate in a certain way, knowing that: governments only have a certain lifespan, a programme is never really a programme, timescales are never timescales*" (P27). These tensions from contrasting cultures are manifested in unpredictable procurement processes that make it difficult for suppliers to plan.

4.3 Organisational Processes of Startup Suppliers

Those with experience working in startups also discussed how their experience of procurement complications related to financial, staffing, and strategy processes. As in the case of PSBs, startup suppliers' temporal dynamics also compounded systemic challenges, albeit in different ways (Figure 3). These results were predominantly informed by those working in GovTech startups. Analysing the perspectives of those who had experience in other types of organisations, including PSBs and larger technology suppliers, served as additional data to confirm our results.

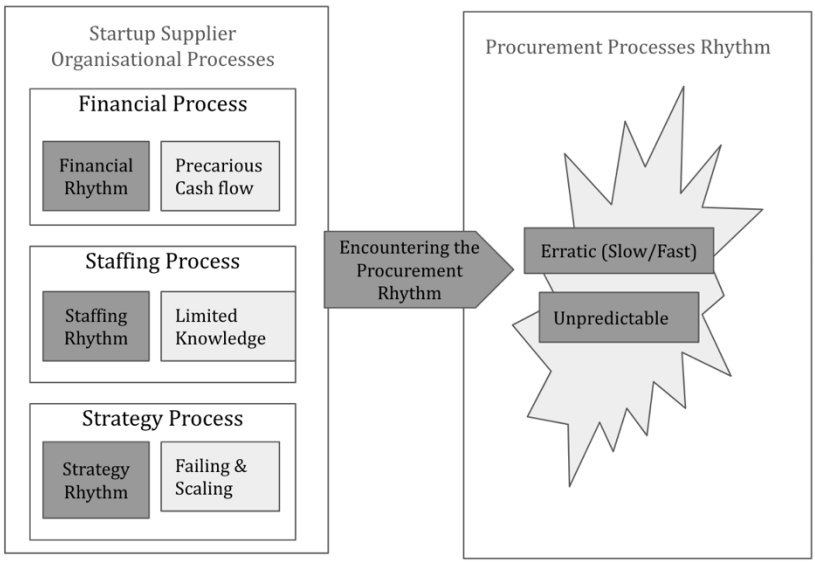

Fig. 3 – Startup Supplier Organisational Processes Encountering Procurement Rhythm

Financial Processes: Startups face challenges of constrained financial resources compared to larger suppliers. The temporal dynamic—of founders balancing their funding and revenue, on the one hand, and their expenses, notably paying employees and developing technology, on the other—was encapsulated by one supplier as "*cash flow is king*" (P16). In part because of limited financial resources and the strategic goal of scaling quickly, many startups seek external funding, often in the form of Venture Capital (VC). This imposes a financial rhythm of raising every 12 to 18 months, which can further complicate temporal dynamics. As we will see in subsequent sections, this creates challenges for startups encountering the rhythm of procurement.

Staffing Processes: Many startups discussed the challenge of lacking dedicated expertise in public sector sales, compared to larger companies who had bidding teams (P4, 5, 13, 21). Due to financial processes, many startups without large VC funding must retain staff on short-term contracts. One founder explained: "*We make do with*

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

subcontractors, and we can't really build a proper team" (P6). This staffing rhythm was compared to consulting firms by participants with experience in both types of companies, where "*the beauty of a human consulting service model is you can move to [government as a secondee] and you don't lose things when the winds have slowed down… If you're selling a technology product you can't. The IP is the thing, and the thing can't move with you*" (P31).

Strategy Processes: Participants discussed the systemic constraints for startups that necessarily have to try and scale. Compared to the United States' large internal market for the public sector (P21) or the consortium buying of Norway (P24), the UK's market is smaller and more fragmented. This creates challenges for suppliers trying to scale by selling to multiple public sector customers because the "*route to market is a sort of jigsaw puzzle*" (P1). Conversely, large technology suppliers benefit from their scale to "*absorb the instability*" (P27). However, temporal dynamics frustrate startups' capacity for long-term planning. "*Time to market is the critical thing for a startup*", both to develop technology, find product-market fit, and avoid running out of resources.

4.4 Challenges for Startups Encountering Procurement Process Rhythm

Startups that seek to sell to the public sector encounter the erratic and unpredictable procurement process rhythm. As they do so, their organisational processes create challenges in predicting this rhythm (Figure 3). Those who overcome the prediction challenge face further difficulties synchronising with the procurement rhythm. Finally, those who synchronise successfully face tensions in managing multiple rhythms.

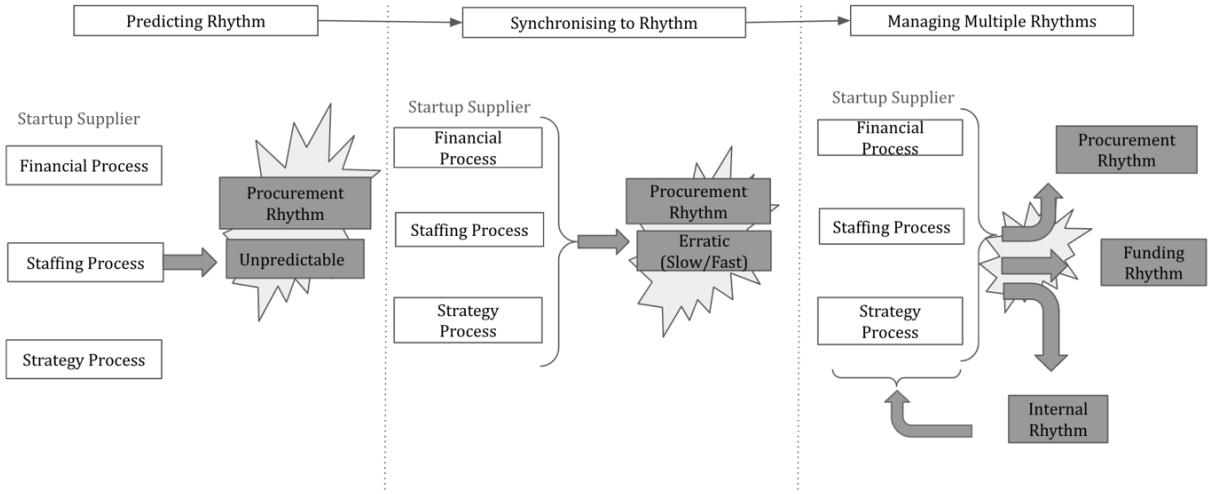

Fig. 4 – Challenges for Startup Suppliers Encountering Procurement Rhythm

Predicting Rhythm: As Figure 4 shows, to successfully bid, suppliers must navigate identifying relevant opportunities and frameworks. Joining most frameworks is time-consuming and uncertain, and they re-open for new entrants infrequently. Finding bidding opportunities was described by one as a "*waste of time*". Another claimed, "The system favours the incumbents who are happy to let things happen slowly". Many suppliers also discussed finding opportunities late. The rise of new e-procurement startups further reinforces the view that temporal dynamics disadvantage some suppliers. These mediators have built fast-growing businesses addressing these pain points. One successful e-procurement startup brands itself as enabling users to "*keep a pulse on their market and the opportunities that they should be chasing down*" and stay "*proactive*" (P22).

Synchronising with Rhythm: Given these temporal dynamics, there are challenges around government sales cycles. Startups "*try and offer purpose-built stuff for the public sector, but nine times out of ten get killed by the long sales cycles*". Short contracts exacerbate slow processes. One startup founder described their attempts to align various short-term contracts and maintain cash flow. Startups on short-term contracts "*don't know if it's going to continue*" (P9). This is further aggravated by high churn. A former startup CEO noted that the combination of slow sales cycles and fast turnover is "*completely deadly*" (P21). This combination was also noted by a former founder whose startup had gone bankrupt. He explained, "*People move on so fast… If you're dealing with early-stage tech companies, two-year postings are not very helpful*" (P16). An experienced civil servant explained how this temporal misalignment is "*Bad for startups or anyone trying to innovate... We end up with those that are the most stable companies with the deepest pockets becoming the easy buys*" (P27). Startups "*wade*" through the time-consuming bidding process under rushed deadlines (P25). This raises the question articulated by one interviewee – "*how can people pace themselves and move in a way that aligns with government cycles* (P31)?" The difficulties in aligning internal rhythms with the public sector go some way in explaining why many startups fail when selling to government, and why others never try to begin with.

Other participants described adapting their behaviour to align with the public sector. One digital consultant who

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

worked closely with startups explained startups' varying levels of success in "*pacing*" themselves to "*align*" to these cycles (P15). They explained that for many smaller suppliers, "*bidding doesn't come naturally*". Others "*know how to bid [and] have their own rhythm*". Those with bidding teams "*have their own cadence of how they do things*". Reflecting on their firms' success selling products and services to the public sector, they described how "*unlike a lot of other SMEs, we are quite in tune to what those rhythms look like*". Another former employee of the same firm mirrored this sentiment. The firm's "*evolution is a story of reacting to the signals being sent in the dance that we do with government. As they sort of slow... you kind of cue each other's movements*" (P31).

Managing Multiple Rhythms: While some startups struggle to synchronise to government cycles altogether, others face difficulties because they synchronise to these same cycles. As Figure 3 shows, startups can face tensions between procurement rhythms and their internal rhythms. For example, startups can become "*addicted to grant funding*" (P16) – dependent on a succession of precarious short contracts. This creates problems in retaining permanent staff and developing technology (P6, 32). "*User input is crucial*" for technological development as it enables startups to "*learn something and iterate from it*". However, in GovTech there are often "*less opportunities for…internal feedback*" (P31). These barriers are amplified by small, short-term contracts because "*Startups can't build products because the contracting mechanisms and what government is asking for don't correlate with the cost of developing technology*" (P32). A succession of short-term contracts creates challenges for intellectual property and hiring staff.

A second tension arises between the procurement and funding rhythm. As GovTech startups try and scale, many face barriers from investors sceptical about government customers. Due to the speed of procurement sales cycles, many Venture Capital Investors (VCs) see startups selling to government as "*un-investable*" (outside of Defence) (P30). For those who can attract external investment, the cadence of fundraising every eighteen to twenty-four months clashes with government sales cycles. Startups expressed an awareness that they will "*die if they don't raise again*" (P17). VC timelines are, therefore, a source of further tensions for public-sector-facing startups. These barriers have a cascade of disincentivising effects. Eight interviewees discussed startups bankrupting themselves when trying to sell to PSBs.

5. Discussion

Based on this single explorative case in the UK, our findings make a series of empirical and theoretical contributions with implications for policymakers and practitioners.

5.1 Empirical Contributions

First, we address calls for further research into the role of public procurement as a barrier for GovTech and the need for empirical case studies (Bharosa, 2022; Hoekstra et al., 2023). We identify barriers that prevent increased procurement from startups. In doing so, we nuance previous studies of public procurement from SMEs (Loader, 2013), disaggregating the specific experiences of GovTech startups due to their characteristic goals of developing novel technologies, disrupting markets and scaling quickly (Hoffman & Yeh, 2018). Second, we provide rigorous empirical evidence to demonstrate the role temporal dynamics play in GovTech barriers (Figure 1), confirming previously anecdotal evidence in the grey literature and further developing lines of argument in recent work (Hoekstra et al., 2023).

5.2 Theoretical Contributions

This paper makes two distinct theoretical contributions: (1) a general contribution to procurement theory and public sector innovation by illuminating underlying temporal dynamics beneath surface-level issues like perceived slowness, suggesting systemic rather than simplistic 'speed-up' solutions; and (2) a specific contribution to GovTech scholarship by revealing the unique temporal tensions faced by startups due to their position at the intersection of innovation, scaling pressures, and public sector processes.

Conventional understandings of the procurement barriers have focused on the systematic constraints that PSBs and startup suppliers face. By using "time as a research lens" (Ancona et al., 2001; Blagoev et al., 2023), we elucidate the complex temporal dynamics of GovTech procurement. While confirming that time plays an important role, our contributions challenge the assumption that underpins much of the GovTech discourse – that the conflict can be reduced to a heuristic of government being slow, startups being fast. Our research also surfaces the role that rushed government processes play in limiting GovTech procurement, "precluding strategic possibilities" (Kaplan & Orlikowski, 2013). We show that there are multiple conflicting rhythms within PSBs (D. Ancona & Chong, 1996; Bluedorn, 2002). These enact a procurement rhythm that is erratic and unpredictable. This may explain irrational-seeming procurement processes that procurement scholars have primarily attributed to conflicting policy objectives (Lember et al., 2014, 2015).

Rather than a uniform slow pace, the varied and erratic rhythm of PSBs creates challenges for the GovTech startups

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

that encounter them. Startups struggle to predict the rhythm of buyers and to subsequently synchronise with them. Nuancing more simplistic accounts that can be found in individual interviews with startups or in the grey literature, procurement challenges cannot be attributed solely to an incompatibility between 'fast' startups and 'slow sales cycles'. This is just one challenging temporal dynamic among many as startups attempt to manage multiple rhythms.

5.3 Implications for Practitioners and Policymakers

The findings of this research provide several practical insights for policymakers and practitioners aiming to enhance GovTech procurement from startups. Rather than solely focusing on simplifying procurement rules or enhancing buyer capacity, it is crucial to also develop a deeper understanding of how temporal dynamics and rhythms across the public sector and GovTech ecosystems align or misalign. Policymakers should look beyond simply accelerating procurement processes and instead improve how procurement rhythms are communicated and managed, helping startups better predict and synchronise their internal processes with public sector cycles. For instance, the recent introduction of pipeline notices under the new UK Procurement Act represents a promising initiative. If effectively implemented, these notices could greatly enhance suppliers' ability to anticipate procurement rhythms and better prepare their bidding and financing strategies accordingly. Improving transparency around procurement timings and rhythms could thus significantly mitigate the temporal barriers identified in this research. Additionally, addressing temporal misalignments not only facilitates greater involvement of innovative suppliers but also helps avoid problematic dependency on large incumbent providers. In light of unfolding geopolitical developments, this could also positively impact digital autonomy by promoting a more diversified and resilient supplier ecosystem within the public sector.

5.4 Limitations and Future Research

As a single case study, more work is required to validate these findings and test their applicability to other contexts. The findings are primarily based on experts' perceptions of barriers and would benefit from alternative methods, including quantitative research. Specific boundary conditions, such as the UK's distinct administrative, budgetary, and legal environment, limit the direct generalisability of our findings to other national contexts. We recommend future research pursue some of the lines of inquiry opened by this case study and continue to explore the fruitful cross-pollination of temporality and digital government.

Future research should examine how specific policy interventions could help address these temporal misalignments whilst supporting greater strategic autonomy in government technology procurement. This might include studying how procurement vehicles could be redesigned to better balance the competing needs for innovation, stability, and sovereign control; investigating how successful GovTech startups navigate competing timeframes whilst building sustainable public sector solutions; or exploring how digital technologies themselves might help bridge these temporal gaps without creating new dependencies. There is also scope for comparative studies examining how different jurisdictions manage temporal dynamics in their GovTech ecosystems whilst maintaining appropriate levels of digital autonomy. Given the growing importance of GovTech in public sector digital transformation, understanding and addressing these temporal barriers will be crucial for fostering more effective and sustainable public-private collaboration in government technology innovation.

6. Conclusion

Commentators often claim that public procurement is broken. This study has shown how temporal dynamics play a critical role in frustrating the stated policy goal of increasing public procurement from GovTech startups. While conventional wisdom frames the challenge as a clash between "slow" government and "fast" startups, our findings suggest a more complex and patterned problem: the erratic and contradictory procurement rhythms enacted by public sector organisations. Startups struggle not only with delays but with unpredictability and misalignment with multiple rhythms. Fixing procurement will require more than government moving faster—it will require learning to better move together. To do so, researchers must continue to explore time as a structural feature of governance—and policymakers must begin to take time seriously.

Appendix

Below is a sample protocol used for interviews with public sector buyers. Similar structures were used for other stakeholder groups (e.g., startup founders, intermediaries), with content tailored accordingly. All questions were followed by flexible prompts depending on interviewee responses.

Core Question	Associated Prompts & Follow Ups
1. Can I confirm you understand and agree with the informed consent procedures?	
2. Could you describe your current role and how you got there?	Perceptions of UK procurement; motivation for working in procurement.
3. In what ways do you interact with procurement in your work?	Organisational context; specific responsibilities; constraints.
4. Can you walk me through the process of recent procurement decision you were involved with in detail?	Specific hurdles; supplier engagement; interdepartmental coordination.

Track 12: Increasing citizen engagement and active citizenship through digital government

Track Description

Citizen engagement has been identified as a crucial factor in several studies seeking to derive benefits from digital government strategies. Making public institutions open and transparent, and generating public value, is a massive challenge that cannot prescind from citizens' participation in the process of thinking, discussing, modeling, approving, implementing, and evaluating public services and solutions. Consultation and participation processes have brought governments and society closer together. However, new challenges await, particularly as society's trust in governments is compromised in many parts of the world, and misinformation and disinformation emerge. Consequently, it is paramount to advance understanding of engagement as an institutional, structural, social, cultural, and political phenomenon, as well as the individual cognitive process of deciding to get involved at all levels, from town to nationwide public management discussion. This track focused on citizen engagement and digital citizenship through active citizen participation in public discourse, aiming to improve digital public services and the impact of digital government.

Abstract. The digital transformation of government services fundamentally reshapes how citizens engage with public institutions and services, creating new opportunities and challenges for inclusive governance in the digital age. Amongst the most critical yet often overlooked stakeholders in this transformation process are children, who represent a significant portion of the global population and the future drivers of digital innovation and civic participation. As digital platforms become central to service delivery, children's unique needs, rights, and vulnerabilities must be explicitly addressed to ensure equitable access, protection, and empowerment. This paper examines the implications of government digital services for children in some selected countries. The paper focuses on governments' role as stakeholders in shaping public services and the importance of contributing to digital literacy, safeguarding privacy, and promoting child-friendly participation mechanisms. Drawing on five-country case studies – Bangladesh, Brazil, Ghana, Sweden, and Timor-Leste - the paper highlights the challenges and opportunities associated with integrating child-sensitive approaches into digital governance. The cases provide insights into how digital government services can increase active citizenship and civic engagement among children and their families while addressing disparities in access and usage. The findings build on a collaborative study conducted in 2021 by the United Nations Children's Fund (UNICEF) and the United Nations University Operating Unit on Policy-driven Electronic Governance (UNU-EGOV). The study underscores the transformative potential of child-sensitive digital government initiatives in promoting early civic participation and empowering marginalized communities. The analysis emphasizes the need for a nuanced understanding of age-specific requirements, improved data collection mechanisms, and a coordinated whole-of-government approach to digital transformation. By integrating child-sensitive practices into digital governance, children's rights are not only safeguarded by governments but also spurs a generation of digital literates, active citizens who are empowered to impact their communities and futures. This paper calls for a concerted effort to prioritize children in digital governance strategies, ensuring that no child is left behind in the digital era. Key contributions include the identification of best practices in inclusive ecosystems, the articulation of a holistic framework for digital service delivery and online safety, as well as the enhancement of strategies for bridging digital divides for marginalized children.

Keywords. Children, COVID-19 Era, Digital transformation, Government digital services, Inclusivity.
Research paper, DOI: https://doi.org/10.59490/dgo.2025.975

1. Introduction

Digital technologies, through rapid advancement, are fundamentally reshaping economies and societies, presenting the potential to permanently transform the nature of modern governance (UNICEF & UNU-EGOV, 2021) and public service delivery. Societal transformations driven by digital technologies have reshaped how individuals interact with governments globally (Van Veldhoven & Vanthienen, 2022). Moreso, it has offered transformative opportunities to improve the efficiency, reach, and quality of government services (Nagy, 2017; UNICEF & UNU-

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

EGOV, 2021) for citizens. The advent of the 'digital evolution' holds the promise of enhanced governance, more inclusive service delivery, and increased responsiveness through the utilization of information and communication technologies (ICT) (Nagy, 2017). Therefore, digital government services have emerged as critical tools for enhancing citizen engagement, streamlining bureaucratic processes, and addressing complex societal challenges (Nagy, 2017; Van Veldhoven & Vanthienen, 2022). Governments worldwide have embraced this transition to e-government, with a central focus on digitizing sectors such as public health, education, social services, and identity management.

During the COVID-19 pandemic, the adaptation of digital solutions accelerated globally (Van der Voort, 2020), demonstrating the potential to maintain essential public services in times of crisis (Amankwah-Amoah, Khan, Wood & Knight, 2021; Janssen & Van der Voort, 2020). However, the accelerated pace of digital transformation also brought to the forefront existing inequalities and created new challenges, particularly for marginalized and vulnerable populations, including children (Ranganai, Muwani, Zivanai, Munyoro & Sakadzo, 2022). Children, as a demographic group, are distinctively positioned in the digital transformative narrative (Keeley & Little, 2017; Livingstone & Third, 2017) as both active users of digital services, particularly in education, healthcare, and social protection and passive recipients of the broader public policies that increasingly rely on digital tools and technologies (UNESCO, 2016; Van Veldhoven & Vanthienen, 2022). Despite their critical significance as stakeholders, children's specific needs and rights are often overlooked in digital governance strategies. Issues such as access disparities, digital literacy gaps, online safety, data privacy, and age-appropriate service design remain underexplored and inadequately addressed in many countries (Fosch-Villaronga, Van der Hof, Lutz, C., & Tamò-Larrieux, 2023; Livingstone & Third, 2017).

Globally, disparities in digital inclusion persist, shaped by socioeconomic inequalities, infrastructural limitations, and governance frameworks (Helsper, 2021). These challenges are majorly present in low-middle-income countries, where children face intense barriers to accessing digital services (UNICEF & UNU-EGOV, 2021). For instance, children in rural areas often struggle with limited internet connectivity, while those in urban poor communities may lack access to affordable digital devices or adequate digital literacy training. In high-income countries with advanced digital infrastructures, gaps in child-focused policies and practices persist, which may undermine the potential benefits of digital government services (Livingstone, Stoilova & Nandagiri, 2019). Addressing these challenges requires a nuanced understanding of the socio-economic, cultural, and institutional contexts that shape digital service delivery for children (Hammond, Polizzi & Bartholomew, 2023).

Furthermore, the rapid digitization of government services raises critical questions about equity and inclusivity (Latupeirissa, et al., 2024; Ranchordas, 2022). Are these services designed to accommodate children from diverse backgrounds, including those with disabilities, those from minority groups, and those living in fragile contexts? Are the risks associated with increased online engagement, such as cyberbullying, exploitation, and exposure to harmful content, adequately reduced? While digital technologies offer transformative potential, their benefits cannot be fully realized without addressing these pressing challenges. Consequently, digital services have become increasingly common in the 21st century; their significance has been magnified during the global COVID-19 pandemic, especially for children and their families (Robinson, et al., 2020; Mok, Xiong & Bin Aedy Rahman, 2021). This presents a pressing need to ensure digital services align with inclusivity, child rights, and safety. Despite the potential of digital services to improve the relevance and accessibility of services for children, there is a lack of systematic comprehension regarding available service types and the facilitating factors that guarantee their alignment with inclusivity, child rights, and safety (Latupeirissa, et al., 2024). The need for systematically exploring the discourse and the practices that ensure government digital services advance and protect the rights of children and young adults cannot be overemphasized (Hammond, Polizzi & Bartholomew, 2023; Ranchordas, 2022). Governments must enhance their capacity to secure data and address the demands of parents and society in ensuring inclusivity, online safety and delivering improved services.

The article critically examines the challenges and opportunities of digital government services for children across five diverse countries: Bangladesh, Brazil, Ghana, Sweden, and Timor-Leste. These countries were selected as they represent a broad spectrum of socio-economic development, different levels of government maturity, and digital infrastructure; providing valuable insights into how digital transformation impacts children in varied contexts. Bangladesh and Ghana, for instance, highlight the barriers faced by low-income nations with limited resources (Graham, 2019), while Brazil showcases a middle-income country's efforts to balance rapid urbanization with digital inclusion (Mazzucato, 2024). In contrast, Sweden exemplifies the approach of a high-income nation with advanced digital systems (Ericsson & Mealy, 2019), and Timor-Leste offers a unique perspective as a post-conflict country striving to build a resilient digital future (McWilliam, 2020). An in-depth study analysis was conducted on the countries' government and norm-setting institutional websites (UNICEF & UNU-EGOV, 2021). Explorative interviews were also conducted in 2021 to complement the data collected from the respective government repositories. The findings of this study underscore the urgent need for child-sensitive digital government strategies that prioritize inclusivity, equity, and the protection of children's rights.

This article adds to the extant literature and makes key contributions, including a holistic framework for online

safety and advancing strategies for bridging digital divides for marginalized children. It extends theoretical discussions by linking digital government services to active citizenship and early civic engagement. Practical and actionable recommendations for creating a safer, more inclusive digital future for children are proposed for policymakers, educators, and technologists. By integrating child-centric perspectives with strategies for inclusion and equity, the study provides a roadmap for creating safer and more inclusive digital ecosystems for children globally. The remaining part of the paper is structured as follows: Section 2 describes the research methodology used to conduct the study. Section 3 discusses the findings relating to the key issues and challenges raised in the study, and proposes a holistic whole-of-government framework for delivering government digital services. Sections 4 and 5 conclude with the article's conclusion and recommendations for ways forward and further analysis.

2. Methodology

2.1 Global survey

A comprehensive global survey of government and norm-setting institutional websites was conducted (UNICEF & UNU-EGOV, 2021) to address the persistent issues mentioned in the introduction. The survey aimed to identify the digital services available to children and their families, focusing on understanding their unique needs, rights, and vulnerabilities (Keeley & Little, 2017; Singh, et al., 2020). The survey also sought to uncover gaps in accessibility, usability, and inclusivity, highlighting areas where digital government services could be improved to better serve marginalized and underserved communities.

A thorough review of relevant academic and grey literature was conducted to complement this approach. The review provided a foundational understanding of the broader socio-political and technological contexts in which digital services are developed and implemented. It also provided insights into best practices, emerging trends, and persistent challenges in digital governance for children. Furthermore, to know citizens' perspectives, explorative interviews were conducted with 28 representatives from government institutions, civil society organizations, and international bodies (UNICEF & UNU-EGOV, 2021). These interviews provided nuanced, context-specific insights into the five countries' design, implementation, and challenges of digital government services.

2.2 Case Study Analysis

All five countries were selected based on their varied socioeconomic conditions, levels of digital infrastructure, and strategic approaches to digital governance. Bangladesh and Ghana represent low-income countries grappling with significant barriers to digital inclusion, such as limited connectivity and resource constraints (Graham, 2019). Brazil is a middle-income country demonstrating the complexities of balancing rapid urbanization with equitable digital access (Mazzucato, 2024). Sweden is a high-income country with advanced digital infrastructure and presents best practices and innovative strategies for inclusivity (Ericsson & Mealy, 2019; UNESCO, 2020). Finally, as a post-conflict state, Timor-Leste provides a unique perspective on the challenges and opportunities of building resilient digital systems in fragile contexts (Ribeiro, Clarke & O'Donoghue, 2020; Timor-Leste Ministry of Education, 2022).

The findings from the survey, literature review, and interviews have been synthesized to provide a holistic understanding of the challenges and opportunities associated with digital government services for children. Key themes explored include accessibility, digital literacy, online safety, data privacy, and the alignment of digital services with child rights and inclusivity principles. Table 1 below presents a concise overview of all five countries, highlighting their socio-economic profiles, digital maturity levels, and strategic focus areas for digital government services. This contextual information global survey and case study analysis are critical for understanding the impacts of digital transformation on children and for identifying scalable and context-sensitive solutions that prioritize equity and inclusivity.

Tab. 1 – Countries considered for the study and a brief description of each.

Country	Income group	Structural set-up	Area of interest
Bangladesh	Low-income	Federal, with central coordination of digital transformation. Federal authorities deliver the majority of services. Weak local authorities.	An emerging Asian economy where digitizing services, increased inclusion, and accessibility in rural areas is a key strategic focus (https://a2i.gov.bd/).
Brazil	Medium-income	Federal, strong state, and local government rights and autonomy. The majority of services are delivered by state and local authorities. A	An emerging Latin American economy, where the rights and well-being of minors follow a mainly classical ICT approach.

		mix of strong and weak local authorities.	
Sweden	High-income	Unitary, strong central government coordination but with decentralized implementation. Over 70% of services are delivered by local authorities.	A European country known for its innovative approaches to education (e.g., educational outcomes, blended play, and experience-based learning) and also technology.
Ghana	Low-income	Unitary, strong central government coordination. The central government delivers the majority of services. Weak local authorities.	Emerging African economy with an emerging tech scene and increased focus on public sector transformation and access to technology and government services.
Timor-Leste	Low-middle-income	Unitary, strong central government, no regions or local authorities. The central government delivers all services.	Asian and emerging within the tech scene. Beginning to aim towards public sector transformation, access to digital technology and services.

Source: Author, UNICEF & UNU-EGOV

The selection of countries also aims to provide a diverse representation, encompassing various levels of economic development, a spectrum of service portfolios, and different stages of governmental digital transformation. For instance, in Table 2 below, Timor-Leste identified as a low-middle-income country with limited public services, is in the initial phases of ICT infrastructure rollout, accompanied by comprehensive plans for e-government. In contrast, Sweden, a high-income welfare state consistently ranked amongst the top 10 countries globally in e-government development, offered a contrasting perspective with its advanced digital transformative initiatives.

Tab. 2 – Current socioeconomic indicators of case countries.

Indicator Description	**Bangladesh**	**Brazil**	**Ghana**	**Sweden**	**Timor-Leste**
Population, total (World Bank, 2023)	171.47	211.14	33.79	10.54	1.38
Percentage of the child population	38.79	32.99	47.83	23.12	59.69
Urbanization (Worldometer, 2024)	42%	91%	57.90%	87.0%	36%
GNI per capita ($) (PPP) (World Bank, 2023)	9,510	20,470	7,450	71,780	5,620
Literacy rate (% ages 15 - 24) (WB)	95% (2021)	99.28% (2022)	93.48% (2020)	99% (2023)	85.10% (2020)
Employment to population ratio (% ages 15 and above – modeled ILO estimated)	55.73%	57.9%	66.38%	62%	65.5%

(WB, 2023)					
Youth not in school or employment (% ages 15 and above) (WB, 2020)	27.39	24.16	30.50	6.13	20.95
Internet users (% of the population) (WB, 2023)	44.50%	84.15%	69.84% (2022)	95.70%	40.75% (2022)
Mobile phone subscriptions (per 100 persons) (WB, 2022)	105.26	98.89	119.62	125	110
E-Government Development Index Ranking (UNDESA, 2025)	0.6570	0.8403	0.6317	0.9326	0.4020

Source: Author. Adopted from UNICEF and UNU-EGOV, 2021, and updated to current data.

2.3 Development and preparation of semi-structured interviews

The interview guide and questions were mainly developed, drawing upon literature from government repositories, academic publications and reports. These resources provided a solid foundation for framing the questions (International Social Security Association, 2019; Neilson, 2019), ensuring they addressed the specific aspects of digital government services for children and their families. The interview was designed to explore a range of topics, including accessibility, usability, inclusivity, data privacy, and the overall impact of digital government services on children. To capture the diverse needs and experiences of children, the study focused on three distinct age groups:

- Infants and young children (ages 0-4): This group primarily relies on their parents and guardians to access government services. Questions for this group focused on the impact of digital services and the role of parents or caregivers in navigating these systems.

- School-age children (ages 5-14): As direct beneficiaries of many government services, such as education and healthcare, this group often accesses digital services through intermediaries like teachers, healthcare providers, or family members. The questions emphasized their experiences and the effectiveness of intermediaries in facilitating access.

- Adolescents (ages 15-18): This group has growing independence and, in many cases, legal rights comparable to those of adults. Questions addressed their direct use of digital services, their perspectives on accessibility and usability, and their awareness of privacy and data protection issues.

The semi-structured interview underwent multiple rounds of review and refinement to ensure cultural sensitivity and contextual relevance. It was designed to facilitate open-ended responses, encouraging interviewees to share detailed insights and personal experiences related to digital government services. The interview guide will be shared via email upon request.

2.4 Data collection and field activities

The data collection process was a collaborative effort between UNICEF and UNU-EGOV, with a focus on ensuring comprehensive and representative findings. The first step involved the careful selection of the five case countries listed in Table 1 above. The countries were chosen to reflect a diverse range of socio-economic conditions, levels, and stages of digital transformation, and their strategies for digital governance. The next phase involved identifying key stakeholders, including government agencies, non-governmental organizations (NGOs), international non-governmental organizations (INGOs), civil society organizations (CSOs), and other relevant entities. Potential interviewees were selected based on their expertise and involvement in digital service delivery, policy-making, or

advocacy relating to children's rights and digital governance.

The data collection exercise took place between February and April 2020. Semi-structured interviews were conducted using the prepared interview guide. This allowed for flexibility in probing specific themes while maintaining consistency across interviews. The interviews were carried out by team members from both UNICEF and UNU-EGOV (UNICEF & UNU-EGOV, 2021), ensuring a balanced representation of expertise and perspectives during the data collection process. Furthermore, field activities included the analysis of policy documents, government reports, and service delivery frameworks to contextualize the insights from interviewees. This multi-method approach ensured a robust understanding of the challenges and opportunities associated with digital government services for children. This systemic and collaborative process allowed the study to generate detailed context-specific findings that highlighted the transformative potential of the digital services of the case countries while also addressing the specific needs and vulnerabilities of children in the case countries.

3. Findings and Discussion

3.1 The general state of affairs of digital services for children globally

Accessing digital services in recent times has created a unique space for children, transforming them into active users of the internet and digital technology (Janssen & Van der Voort, 2020; Keeley & Little, 2017; Fosch-Villaronga, Van der Hof, Lutz & Tamò-Larrieux, 2023; Helsper, 2021). Thus, the rise in internet connectivity and the availability of digital platforms have significantly reshaped how children interact with the world (Keeley & Little, 2017). This transformation has been further accelerated by the advent of the COVID-19 pandemic, which has necessitated the shift to online spaces for education, healthcare, and various social and entertainment activities – many of which have educational components. These developments have redefined childhood experiences, creating new opportunities and challenges for minors in the digital age.

Global data highlights the pervasive reach of digital technologies, with an estimated 3.89 billion people in 2018 (Hammond, Polizzi & Bartholomew, 2023; Hernandez & Roberts, 2018). However, since COVID-19, this has increased to an estimated 5.52 billion people, which is equivalent to 67.5% of the world's total population (DataReportal, 2025). Following this new and intense era of crisis for children and recent technology trends, the potential risks for children have indeed become a continuation of the reality of the past several years. Children aged 15 years and older have emerged as the most avid subgroup of minors and young adults connected online. As of 2023, approximately 79% of children and young adults aged 15 to 24 globally are active Internet users (International Telecommunication Unit, 2023). This indicates that 21% of the age group remains unconnected (ITU, 2025).

A growing body of evidence underscores the multifaceted benefits of digital access for children (Hammond, Polizzi & Bartholomew, 2023; Keeley & Little, 2017). Access to digital services has proven instrumental in various ways, particularly in education (Haleem, Javid, Qadri & Suman, 2022; Williamson, 2017). Online school activities and out-of-school educational resources are two prominent avenues through which children leverage digital technologies (McNaughton, et al., 2022). These tools have democratized access to quality education, enabling learners to access diverse resources and engage with interactive content irrespective of geographic or socioeconomic barriers (Keeley & Little, 2017). However, the advantages of digital opportunities extend far beyond education (Parveen & Ramzan, 2024). Children engaging with digital services, particularly in the global northern hemisphere, encounter various opportunities, including developing digital literacy and communication skills and exploring creative and innovative activities (Haddock, Ward, Yu & O'Dea, 2022). For instance, digital platforms often serve as spaces for collaboration, where children can connect with peers globally, exchange ideas, and participate in social and civic initiatives and engagements.

Findings from the 2018 Programme for International Students Assessment (PISA) reveal that 95% of 15-year-olds across OECD countries have access to some form of digital services (Avvisati & Givord, 2021). This high level of connectivity suggests that digital technologies have become an integral part of young people in the global northern hemisphere. However, notable disparities exist in accessibility and usability across different demographic and geographic groups, particularly when considering children in the global south. More so, while substantial data on internet usage by adolescents aged 15 to 18 exist, there still remains a significant gap in the digital experiences of younger children aged 0 to 14 (Livingstone, Stoilova & Nandagiri, 2019).

The literature review revealed limited data on the ages of 0 to 14, leaving gaps and critical questions on their technology access and usage patterns. Furthermore, other significant indicators such as gender, age, and geographic location are often underexplored, resulting in an incomplete understanding of the state of affairs or digital landscape for children. This lack of data poses a challenge for policymakers, educators, and stakeholders aiming to ensure equitable access and address the risks associated with digital engagement (Livingstone, Stoilova & Nandagiri, 2019). To address these gaps, there is a pressing need for comprehensive research that explores the digital experiences of younger children, disaggregated by key variables such as age, gender, socioeconomic status,

and geographic location.

3.2 Accessibility

The study revealed significant disparities in children's access to digital government services, primarily driven by socioeconomic and geographic factors. In low- and middle-income countries such as Bangladesh and Ghana, inadequate infrastructure and high costs of digital devices are major barriers. For instance, recent ITU (2023) statistics show that only 40% of households in low-income countries have internet access, compared to 90% in high-income countries. More so, rural areas often lack the connectivity needed to access digital services, leaving children in these regions disproportionately disadvantaged.

In Bangladesh, programs such as "*Digital Bangladesh*" aim to improve access by providing internet-enabled education hubs and affordable devices (Digital Bangladesh Vision, 2020; United Nations Development Programme, 2021). However, logistical challenges and resource constraints often limit their reach (Dappe, Kunaka, Lebrand & Weisskopf, 2019). Ghana has made advancements with initiatives such as public-private partnerships to expand connectivity, yet progress remains slow in rural areas. Furthermore, these challenges are spurred by socioeconomic inequalities, as families in lower-income brackets often prioritize basic needs over digital resources.

In Timor-Leste, digital transformation is in its nascent stages (Timor-Leste Ministry of Education, 2022), facing unique challenges, including the lack of localized content and limited awareness of digital tools among educators and parents (Ribeiro, Clarke & O'Donoghue, 2020). Community-based approaches, such as local internet hubs and collaborative education platforms, have shown promise (Srinivasan, Jishnu & Shamala, 2021) but require scalability and sustainability to create a meaningful impact (Guglielmi et al., 2021). In contrast, Sweden exemplifies best practices through universal broadband coverage and subsidized digital services and devices for students, ensuring equitable access (Lazar, Goldstein & Taylor, 2015). However, in high-income countries, children from immigrant and minority backgrounds often encounter linguistic and cultural barriers to accessing government digital services, highlighting the need for tailored approaches and alignment to inclusion.

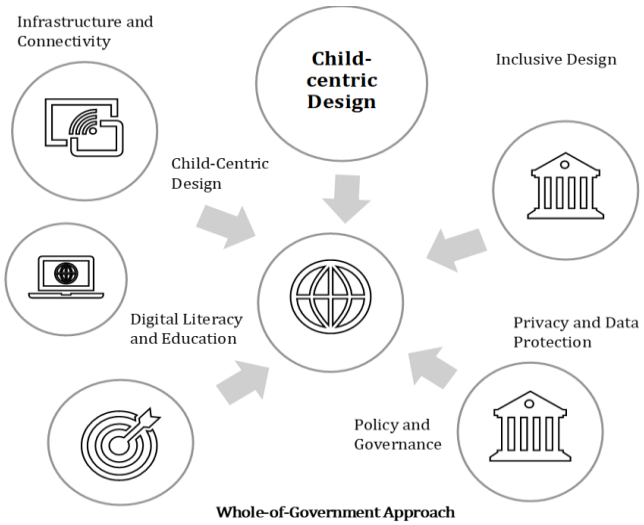
3.3 Online Safety

Online safety emerged as a critical concern across all case study countries. Children's increased use of digital platforms has brought about exposure to risks such as cyberbullying and identity theft, as well as exposure to harmful content. According to the UNICEF report (2021), 1 in 3 internet users globally is a child. Yet, fewer than half of all countries have implemented comprehensive online safety policies that align with the needs of children online. In Brazil, the legal framework for child protection in digital spaces includes initiatives for eliminating cyberbullying and preventing exploitation (Third, Livingstone & Lansdown, 2019). However, there are gaps in enforcing these laws (Brazilian Internet Steering Committee, 2021), leaving children vulnerable, especially children in underserved regions where digital literacy remains low.

In Ghana and Bangladesh, vulnerabilities are exacerbated by limited awareness among parents and educators. Thus, children are often left to navigate online spaces without adequate guidance or safeguards (Ghana Investment Fund for Electronic Communications, 2022; United Nations Development Programme, 2021). These regions urgently need structural training programs to educate stakeholders on digital safety practices engagement (Livingstone, Stoilova & Nandagiri, 2019). Sweden has proactive measures in place, such as "Digital Resilience Programs," which are integrated into school curricula (Swedish National Agency for Education, 2021). These measures ensure that children are taught how to identify and mitigate online risks. The programs also lay emphasis on parental involvement, recognizing the critical role-play of families in promoting safe online behaviors.

3.4 Inclusivity in Education

Digital education holds immense potential to bridge learning gaps, yet inequalities are often intensified (Bozkurt, et al., 2020). The COVID-19 pandemic exposed the fragility of digital education systems, particularly in low-income countries (Srinivasan, Jishnu & Shamala, 2021; West, Kraut & Ei Chew, 2019). In Ghana, only 20% of students had access to online learning platforms during school closures (Agormedah, Henaku, Ayite & Ansah, 2020; GIFEC, 2022; Owusu-Fordjour, Koomson & Hanson, 2020), compared to almost universal access in Sweden (Pramling Samuelson, Wagner & Eriksen Ødegaard, 2020; SNAE, 2021). These disparities showcase the urgent need for targeted intervention to ensure inclusivity.



Innovative solutions, such as mobile-based learning platforms and community internet hubs, have shown possibilities in improving access in resource-constrained settings (Srinivasan, Jishnu & Shamala, 2021). For instance, Brazil has presented programs that use television and radio to deliver educational content to students without internet access, ensuring a broader reach (Brazilian Network Information Center, 2021). More so, partnerships with technology companies have enabled the distribution of low-cost tablets and preloaded educational content to underserved communities (NIC.Br, 2021; Third, Livingstone & Lansdown, 2019).

Sweden's inclusive education model incorporates assistive technologies for children with disabilities and multilingual platforms for immigrant students, ensuring no child is left behind (Tajic & Bunar, 2023; UNESCO, 2020). The findings emphasize the significance of integrating digital literacy into school curricula, providing teacher training on digital tools, and ensuring that digital platforms are accessible to children from diverse socioeconomic backgrounds. Furthermore, creating partnerships between public institutions and private organizations can help fund innovative solutions for inclusive education ((Tajic & Bunar, 2023).

3.5 Government digital services for increased citizens' engagement

This section presents a holistic framework to illustrate some of the key components and interconnections required to design and deliver inclusive and effective government digital services for children in all five case study countries.

Fig. 1 – Framework for Government Digital Services

Source: Author

Elements in the framework play a critical role in ensuring that services are accessible, equitable, and responsive to citizens' needs, especially children. The infrastructure and connectivity pillar presents the foundational layer of digital services (Camarinha-Matos, Fornasiero, Ramezani & Ferrada, 2019; Serrano, 2018). It focuses on ensuring that the physical and technological infrastructure, such as broadband networks, mobile towers, satellite coverage and electricity are readily available and accessible, especially in the underserved and remote areas. Thus, without robust connectivity, citizens in marginalized regions risk being excluded from accessing government digital services.

The digital literacy and education component presents the capability of citizens to effectively use digital technologies. Programs within this area must push for the use of digital skills among children, educators, parents and communities. This will help ensure that citizens are equipped to navigate digital or online government platforms, use e-learning tools, and access resources safely and effectively. The Child-centric design pillar focuses on designing digital platforms and services that align with children's unique needs and rights. Services around this pillar must feature intuitive interfaces, age-appropriate content, and tools for meaningful citizen participation. For instance, digital platforms must integrate child-friendly features, such as simplified navigations and visuals that reverberate younger users.

The privacy and data protection pillar highlights the need to safeguard sensitive data, particularly for children, as they may be conversant with the digital risks associated with online activities. It lays emphasis on implementing encryption, anonymization, and robust data protection policies to ensure users' safety (Third, Livingstone & Lansdown, 2019). Legal frameworks and monitoring mechanisms are also critical to enhancing trust in digital systems, especially for children (Felzmann, Villaronga, Lutz & Tamo-Larrieux, 2019). The policy and governance pillar provides the strategic and regulatory framework for the delivery of digital services, emphasizing cross-sector collaboration, inclusive policies, and government accountability. Thus, the governance framework ensures equitable accessibility to resources while addressing the digital divide, cybersecurity, and other challenges.

The inclusive outcomes and whole-of-government approach are the central elements of the framework. The inclusive outcomes represent the ultimate goal of digital services, which are equitable access, inclusion, and

empowerment of all citizens, especially children and marginalized communities. The whole-of-government approach highlights the need for coordination across multiple multilateral collaborators and sectors for the delivery of both unified and seamless digital services for children.

4. Conclusion

The digital transformation of government services continues to present unique opportunities for addressing systemic inequalities and empowering children. However, realizing this potential requires a sustained and strategic commitment from policymakers, educators, and technology developers. The paper examined the challenges and opportunities inherent in using digital platforms to improve accessibility, online safety, and inclusivity for children. The findings emphasize that while significant strides have been made globally, many systemic barriers persist, including infrastructure limitations, socioeconomic disparities, and gaps in online safety. Children's access to digital government services is often dictated by their geographic location, household income, and the availability of localized, culturally appropriate resources (Mathrani, Sarvesh & Umer, 2022; UNICEF & UNU-EGOV, 2021). Addressing these disparities requires efforts toward bridging the digital divide through robust infrastructure investment, affordable access to digital devices and the internet, and policies that prioritize the needs of underserved communities.

Governments must approach digital transformation through a child-centered perspective to ensure that digital services accommodate children's basic needs and actively contribute to their empowerment and protection. Thus, governments must continue adjusting their digital transformation strategies while embracing children's needs. This will require moving beyond short-term fixes to adopt long-term, sustainable strategies that address the root causes of digital exclusion. More so, ensuring that children can safely navigate digital platforms, particularly due to their high susceptibility to risks is of great significance. Governments must implement comprehensive and effective online safety frameworks that balance not only regulation with education but also empower both children and their guardians to use digital tools and technologies responsibly.

Governments must collaborate with international organizations, civil society groups, and the private sector to establish inclusive digital ecosystems. Furthermore, ensuring transparency and accountability in the implementation of digital initiatives. This is critical to building trust and achieving outcomes. Success in digital transformation efforts and initiatives will depend on adapting to evolving technologies while maintaining a persistent commitment to equity, safety, and inclusivity. Finally, the study underscores the need for international and multilateral collaborations to develop and share best practices, including tools for monitoring digital activities and implementing early warning systems and scalable frameworks for cross-border cooperation.

5. Recommendation

The study recommends the following key points:

5.1 Infrastructural expansion

Investing in robust and accessible internet infrastructure, prioritizing underserved and rural areas to bridge the digital divide. More so, governments' introduction of subsidized initiatives and programs will result in digital tools and internet accessibility that are also affordable for low-income families.

5.2 Enhancing online safety

Establishing comprehensive and effective online safety policies that include education on digital risks, implementing robust content filtering systems, and stringent penalties for cybercrimes targeting children. Also, having effective collaborations to develop a unified framework for child online protection.

5.3 Promoting inclusive education

Inclusivity in education remains a key foundation for equitable digital transformation. The integration of digital literacy into educational and school curricula, as well as the provision of continuous professional development for educators and teachers to effectively use digital tools is extremely significant. Also, expanding access to assistive technologies for children with disabilities and designing multilingual platforms to accommodate diverse linguistic needs cannot be overemphasized.

5.4 Pushing for collaboration

Develop multi-stakeholder partnerships that bring together government, non-governmental organizations (NGOs), international organizations, and the private sector to co-create solutions that address accessibility, safety, and inclusion. Making use of public-private partnerships to fund innovative projects and initiatives, and also ensuring the sustainability of these projects and initiatives are significant factors for consideration.

5.5 Implementation of data-driven strategies

Governments must regularly collect and analyze data to monitor the effectiveness of their digital initiative. The use of evidence-based research and/or data to refine strategies, identify emerging challenges, and adapt to the changing technological landscape is critical to the success of any digital transformation journey.

5.6 Encouraging civic engagement and community participation

Actively involve children, parents, and local communities in designing and implementing digital services to ensure real needs are addressed and cultural contexts are considered.

Abstract. Context: Innovation and agility are critical needs in the public administration, driving the development of methodologies that optimize collaborative processes. **Goal**: This study focuses on co-creating a digital solution for a Service Plan of Functions through a Service Design Workshop. We propose and apply a fast track for collaborative Solutions approach, integrating large language models (LLMs) to streamline idea consolidation and facilitate consensus in service design workshops. **Method**: We conducted a workshop aimed at rethinking an existing solution from the perspective of the service user. This involved defining personas, mapping the user journey, proposing functionalities, and aligning these functionalities with the journey stages. **Results**: The proposed methodology significantly reduced execution time and enhanced the efficiency of service design processes involving large groups, without compromising decision quality. The study provides a detailed description of the methodology, the prompts employed, and the outcomes of a case study conducted in a Brazilian public-sector state-owned enterprise.

1. Introduction

The public administration is under increasing pressure to innovate and adapt to rapidly changing societal needs. Collaborative initiatives in this domain often face significant challenges, particularly when organizing ideas and reaching consensus in large, diverse groups. The complexity of these processes is further compounded by constraints on time, resources, and the need to address the interests of various stakeholders (Pajula et al., 2024; Venson et al., 2024). Collaborative decision-making in public administration frequently encounters obstacles such as fragmented communication and misaligned objectives, which can undermine the efficiency and effectiveness of innovation initiatives (**DBLP:journals/jucs/MarsicanoCPRF24**; Leonardi & Not, 2022). Similarly, (Not et al., 2024) highlighted that the growing complexity of public service design requires novel approaches to manage diverse perspectives and foster actionable outcomes.

Studies have identified several critical challenges in implementing co-production processes in public administration. Co-production is defined as a strategy that enables the production of public goods and services through the sharing of responsibilities and power among public agents, private entities, and citizens (Osborne

et al., 2021). There are two main types of co-production: 1) Simultaneous Co-production: This occurs when citizens actively participate during the delivery process of public services, directly collaborating in its execution; and 2) Sequential Co-production: This involves citizen participation in distinct stages of the production process, such as planning, implementation, or evaluation, but not necessarily during the direct delivery of the service. These types highlight different moments and forms of citizen engagement in the co-production of public services (Osborne et al., 2021). Among the key issues are the absence of clear theoretical frameworks to guide public managers, insufficient managerial skills, a lack of tools for effective implementation and capacity-building, and limited awareness among public managers about the concept of co-production (Figueiredo, Venson, et al., 2024), (Figueiredo et al., 2022). These challenges underscore the need for enhanced management education in this area (Pedrosa et al., 2022), (Sicilia et al., 2016). Additionally, other studies highlight that public administrations (PAs) often struggle to determine the starting point for initiating co-production efforts (Leonardi et al., 2023). They frequently lack structured approaches for managing work plans and documentation, face difficulties in overseeing tasks and handovers, and encounter challenges in sustaining processes that span months or even years. The inconsistent and unsystematic use of technology further exacerbates these issues. Public administrations often rely on a patchwork of devices and tools without a cohesive strategy, with inadequate planning for the regular and effective use of ICTs emerging as a significant challenge (Clifton et al., 2020).

Another issue is the lack of a consolidated guidelines of practices or institutional knowledge in co-production. Public administrations often need to reconfigure the process from scratch each time, as there are no established best practices or precedents to rely on (Leonardi & Not, 2022). (Leonardi & Not, 2022) also highlighted the pressing need for guidance in managing the numerosity and heterogeneity of stakeholders involved, as well as the evolving structure of collaborative networks. These challenges are compounded by bureaucratic and cross-organizational barriers that further hinder co-production efforts (Leonardi & Not, 2022). Support is also required to reduce the costs of user engagement and improve its effectiveness. Key strategies include creating collaboration settings that mitigate perceived power asymmetries between public officers and users, enabling continuous monitoring and iterative evaluation of the co-production process, and ensuring its accountability and sustainability. Together, these measures aim to foster a more structured and inclusive approach to co-production, addressing both operational and relational challenges within public administration (Loeffler, 2018).

Traditional methods for facilitating workshops in the public administration, while widely used, often fall short in addressing these challenges. Conventional workshop techniques can be time-intensive and struggle to accommodate the input of large, heterogeneous groups effectively. Furthermore, these methods may not provide the agility needed to rapidly adapt to emerging insights or unexpected constraints during the design process. This inefficiency is particularly problematic in scenarios where timely decision-making is critical (Belkacem et al., 2024). Recently, the Service Design (SD) approach has been used in the context of public services digitization to tackle some of these challenges. SD enables organizations to view their services from the perspective of citizens and those involved in delivering an innovative service (Figueiredo, Venson, et al., 2024; Trischler & Westman Trischler, 2022). It is a user-centered, collaborative, and holistic approach designed to create services that balance the needs of citizens with those of the organization, delivering seamless and high-quality experiences to improve existing services and develop new ones (Koskela-Huotari et al., 2021; Leinonen & Roto, 2023). To address these challenges, this study explores the potential of integrating large language models (LLMs) into collaborative design workshops in the public administration. LLMs, with their advanced natural language processing capabilities, have shown promise in consolidating ideas, generating insights, and facilitating consensus in various domains. However, their application in public administration contexts remains under-explored. This gap presents an opportunity to investigate how LLMs can enhance the efficiency and effectiveness of collaborative processes in this domain. The reliance on traditional methods for organizing and facilitating workshops in the public administration often hinders innovation, primarily due to their limited scalability and inefficiency in addressing the diverse inputs of participants. To overcome this challenge, this study aims to explore the following research question:

RQ.1. How can a "Fast Track for Collaborative Solutions" supported by LLMs optimize design workshops in public service?

We hypothesize that the integration of LLMs into workshop methodologies can accelerate the consolidation of ideas and facilitate consensus among participants, ultimately enhancing the outcomes of collaborative processes. This paper presents the following contributions: i) The development of specific prompts tailored for

the consolidation of ideas and the facilitation of consensus in collaborative workshops; ii) A methodology based on the concept of a "Fast Track for Collaborative Solutions," designed to enable agile and effective workshops, particularly in large and diverse groups; iii) The proposed approach is validated through a case study conducted in a Brazilian public-sector state-owned enterprise. By addressing a real-world challenge in the public administration, this study aims to provide a practical framework for improving service design processes, leveraging the capabilities of LLMs to overcome traditional workshop limitations.

2. Background and Related Work

(Stephen P Osborne & Strokosch, 2016) defined co-production as active or passive participation of public service users in activities such as the design, management, delivery, or evaluation of public services. Co-production of public services signifies that services are not solely delivered by professionals and managers from public agencies but are collaboratively created and subsequently provided to users and citizens (Brandsen & Honingh, 2016; Figueiredo, Pedrosa, et al., 2024). Additionally, (Scupola & Mergel, 2022) defined co-production as a collaborative process where multiple stakeholders (e.g., citizens, public and private organizations) work together to create public value during the digital transformation of public services. This process encompasses three main phases: 1) Co-design: Collaborative planning to address stakeholders' needs; 2) Co-development: Implementation phase where stakeholders jointly build the proposed solutions; and 3) Co-delivery: The cooperative delivery or execution of the developed solutions. This approach represents a more inclusive method for developing and delivering public goods and services, involving citizens, users, and public organization members in the entire process of creation, execution, and long-term sustainability (Sorrentino et al., 2018). Co-production highlights the role of users as active agents rather than passive beneficiaries. This alternative approach often results in better long-term outcomes. The growing interest in promoting more participatory service creation arises from the traditional challenges in delivering public goods and services. Moreover, user participation has been further driven by socio-economic crises and the challenges governments face, including increasing demand for public services, rising user expectations, and, in many cases, constrained government budgets for service provision (Bovaird & Löffler, 2013).

The distribution of power and responsibility between public and private actors can vary significantly, leading to different models of co-production. Stakeholders and users can assist the government in improving public performance and more effectively meeting the desires and needs of citizens. Additionally, the government can help citizens enhance their daily productivity, decision-making, and well-being by offering efficient and easily accessible public services (Linders, 2011). However, achieving this requires diverse collaborative processes, which can be facilitated and influenced by the introduction of ICT in various ways (Capolupo et al., 2020). According to (Not et al., 2024), co-production encompasses a wide range of practices and activities, including the use of Service Design approaches, co-design techniques (involving internal stakeholders, partners, and suppliers), and co-creation practices (with end users). These approaches may involve participants at varying levels of engagement, be applied at different stages of the creation process, and depend on the type of service, the activities, and the strategies and responsibilities involved. (Figueiredo, Venson, et al., 2024) employed a Service Design (SD) approach to foster innovation in public services through co-design and co-creation activities focused on citizen-centered solutions. The methodology was structured into four iterative phases: exploration, creation, reflection, and implementation. The authors applied SD to various government projects and concluded that using SD to co-design and implement public service solutions enhanced stakeholder engagement and contributed to service innovation. Additionally, the iterative practices of SD were found to lead to solutions more aligned with user and organizational needs, enabling the delivery of greater value to society.

Despite the benefits of co-production, it requires greater attention to governance and accountability, and relies on high levels of trust among the various parties involved to achieve successful outcomes (Not et al., 2024). To effectively implement co-production processes and impact traditional public policies and services, organizational structures must be developed with low centralization, high connectivity among actors, and an ethos of mutuality and equality among the different participants, including the end users. Therefore, co-production demands active citizen participation and a more engaged role from public organizations in service delivery (Not et al., 2024). The adoption and use of Artificial Intelligence (AI) technologies by the public administration have grown significantly. Governments have deployed AI systems for predictive policing, cybersecurity defense, regulatory enforcement, adjudicating benefits and privileges, and as chatbots to address citizen inquiries and assist with filling, searching, and drafting documents (Dunleavy & Margetts, 2023; Henman, 2020). With the rapidly increasing adoption of Generative AI (Gen AI) tools by the general public, governments have

begun experimenting with these technologies and issuing guidelines on how they could be used by public administration. Gen AI, in particular, presents opportunities for government organizations not only to enhance their interactions with citizens but also to integrate and leverage their internal knowledge assets to improve the development and delivery of public services (Dunleavy & Margetts, 2023).

AI can be leveraged to enhance government operations and services by designing systems and programs capable of solving problems, learning, perceiving, understanding, reasoning, and becoming aware of their environment (Mellouli et al., 2024). AI relies on identifying and processing data, selecting training datasets, choosing algorithms, conducting training, and evaluating outcomes. These data are often high-volume and pertain to diverse situations with varying complexity and contexts (Mellouli et al., 2024). Among these contexts, public administration stands out as a domain where AI can be applied across various sectors, including health, education, sustainable development, transportation, and the like. AI has emerged as a critical strategic element in government agendas. As public administrations strive to harness the power of AI to better serve their citizens, new opportunities for innovation and efficiency in public administration are arising. AI holds the potential to transform public services and policies, offering innovative capabilities that empower civil servants with enhanced support for decision-making processes (Mellouli et al., 2024; B. W. Wirtz & Müller, 2019). AI acts as a catalyst for creating innovative services for citizens, governments, and public organizations. By adopting AI, governments can unlock substantial benefits, such as improved service quality, increased productivity, and cost-effective service excellence (J. Wirtz, 2020). In this context, this research presents the integration of LLM tools into the design of a workshop aimed at facilitating the rapid collection and synthesis of ideas, agile consensus-building, and the generation of instant feedback and documentation to prototype the improvement of a public service.

3. Research Design

The methodology for this study was designed to evaluate the effectiveness of a fast track for collaborative solutions approach supported by LLMs in a service design workshop for the public administration. This section details the planning, execution, and tools used in the workshop, structured to facilitate rapid idea consolidation, agile consensus-building, and the prototyping of solutions. The agenda incorporated the following stages: 1. Workshop Context; 2. Integration of LLMs; 3) Deliverables; and 4) Evaluation. **1. Workshop Context** The workshop aimed to tackle inefficiencies in the submission and analysis of public service plans, focusing on co-creating a digital solution to optimize these processes. Its primary objective was to redesign the service with an end-user perspective, improving both user satisfaction and organizational efficiency. A total of 28 participants from various roles and public organizations took part in the workshop. These participants included key stakeholders, such as public servants, managers, and technical staff, ensuring a diverse range of perspectives and expertise. The workshop spanned two days, with each session designed to progressively build toward a minimum viable product (MVP) for the proposed service. The Workshop Context stage encompassed the following:

1. Introduction and Contextualization: Participants were introduced to the objectives of the workshop and the processes under analysis. Ice-breaking activities were conducted to foster a collaborative atmosphere, followed by a shared understanding of the existing challenges. The workshop aimed to co-create a digital solution based on the service design approach for the Functions Plan process. #P3 presented the process flow: a) Proposal/Amendment/Reconsideration/Start Process: The process begins when the state-owned company submits a proposal, a plan amendment, or a request for reconsideration; b) Insert Proposal Type: There are four types of analyses: a new functions plan proposal, a functions plan amendment, a request for reconsideration, and proposals with conditions; c) Insert Documentation: The state-owned company must gather all necessary documentation to support the analysis; d) Forward Proposal to Supervisory Ministry: The proposal is sent to the Supervisory Ministry, which verifies compliance with the company's policy and business guidelines; e) Receive Proposal: The proposal is received by Secretariat of Coordination and Governance of State-Owned Enterprises (SEST) (Canedo et al., 2021) to begin the technical analysis; f) Review and Forward to SEST: The proposal is forwarded to SEST for a more detailed analysis; g) Verify Complete Documentation: The first phase of SEST's analysis involves checking the completeness of the documentation; h) Request Additional Information or Proceed: If any documents are missing, SEST requests additional information; i) Merit Analysis: Once the documentation is complete, SEST conducts a merit analysis of the proposal, which involves comparing data and identifying necessary adjustments; j) Review of the

Technical Report Draft: After the analysis, a draft technical report is prepared and reviewed; k) Consolidation/Signature of the Technical Report: The final technical report is consolidated and signed; l) Send Feedback to the Company: After being signed, the technical report is sent to the company along with an official communication; m) Deadline for Compliance with Conditions: If the analysis imposes conditions, the company is given a deadline to comply with them; and n) Conclude Process: The process can be concluded when the company fulfills the conditions. If the deadline passes without compliance, the process is closed without fulfillment.

2. Problem Identification and Consolidation: Participants worked in groups to brainstorm issues related to the current process, using tools such as post-its for idea collection. These ideas were then consolidated into a unified problem statement during a plenary discussion.
   The primary focus of the workshop was the analysis of function plans by SEST, addressing the need to adapt to frequent changes in the dynamic structures of the process workflow. The majority of the workload is related to new plans or modifications to existing ones, while job and salary processes occur less frequently but are more complex. One of the key challenges is ensuring the speed of the process, which involves three main stakeholders: the state-owned enterprise, the analyzing body (such as the speaker's coordination team), and the supervising Ministry.
   #P3 detailed the documentation stages and emphasized the importance of complying with legal standards. There are four types of processes: new function plan proposals, plan modifications, reconsideration requests, and proposals requiring conditional approval. SEST's initial task is to verify the completeness of the documentation. If any documents are missing, the state-owned enterprise is notified to provide the missing items. Technical analysis is then conducted, with the possibility of requesting additional information. At the end of the process, a technical report is prepared and reviewed internally by SEST before being sent to the enterprise. This report may include conditions that the enterprise must fulfill within a stipulated timeframe.
3. Solution Exploration: Through the "Is-Is Not / Does-Does Not" framework, participants explored the characteristics and functionalities of the ideal solution. Group discussions were followed by collective consolidation of the insights.
4. User-Centered Redesign: Using design thinking principles (de Sá Araújo et al., 2019), participants defined personas (Canedo et al., 2023) representing typical users of the service, such as "Luci," a 45-year-old HR manager. Then, they mapped user journeys, identifying pain points and opportunities for improvement.
5. Journey-Based Functionality Design: Functionalities were proposed and aligned with specific stages of the user journey. This phase emphasized prioritization and feasibility, ensuring alignment with user needs and organizational goals.
6. Prototype Development: Low-fidelity prototyping methods, such as storyboards and wireframes, were employed to visualize the proposed solution. Groups collaborated to create initial designs, which were then unified into a final prototype.

2. Integration of LLMs. LLMs were used throughout the workshop to support: 1. Idea Consolidation: Synthesizing inputs from participants to create cohesive problem statements and solutions. At this stage, participants simultaneously shared their contributions through a platform integrated with the LLM. An example of the prompt used: "Group and synthesize ideas on [topic X] submitted by multiple participants, identifying key patterns and main themes." Outcome: A consolidated overview of the primary suggestions; 2. Consensus Facilitation: Summarizing group discussions to streamline decision-making processes. The LLM organized the grouped ideas into clear options for voting or discussion. An example of the prompt used: "Generate three options based on the main ideas, considering different perspectives, to facilitate group decision-making." Outcome: Concrete and structured proposals for decision-making; and 3. Feedback and Documentation: Generating instant summaries of each session, ensuring comprehensive records of insights and decisions. Real-time automated summaries of the discussions and decisions were generated. An example of the prompt used: "Create a detailed summary of the decisions made and the corresponding justifications provided by stakeholders during this session." Outcome: Comprehensive reports of the discussions and decisions finalized at the end of the workshop.

3. Deliverables. The workshop concluded with the development of an MVP (and its prototypes), outlined by a value proposition, user personas, key functionalities, and expected outcomes. This provided a tangible output for stakeholders to further refine and implement. **4. Evaluation**. The methodology was evaluated based on participant feedback, the quality of the MVP, and the efficiency of the workshop process. Metrics included the time required for each stage, the perceived effectiveness of LLM integration, and the alignment of the final prototype with user and organizational needs.

The service design workshop conducted with Startup EstataisGov provided significant insights and actionable outcomes aimed at enhancing the management and submission of public service plans. Held over two days, the workshop facilitated collaborative discussions among key stakeholders, including representatives from public enterprises, supervisory ministries, and SEST. The following section detail the main results achieved, categorized into problem identification, user journey development, functional prototyping, and recommendations for technological and procedural improvements.

4. Results

The central focus of the workshop was to systematically identify and categorize the challenges in the current system for public service plan management. Participants used tools such as post-its and facilitated group discussions to map the primary pain points, which were later consolidated into categories. During **the introduction and contextualization phase**, participants were divided into small groups to gain insights into the problem. After their discussions, they recorded their ideas about the issue on post-it notes. The participants generated 48 insights related to the problem (Function Plan), as summarized in Table 1. During the problem identification and consolidation phase, these insights were processed using a Large Language Model (LLM). The text submitted to the LLM was: *"With a specialized perspective on Service Design, analyze the texts presented in the post-its (1) and organize them into commonly practiced categories. If you cannot identify a word with more than 90% accuracy, ask me".*

In response, the LLM reported successfully analyzing the content and organizing it into categories. Some words or phrases were flagged as open for further clarification regarding their categorization. Overall, the accuracy level was high, as the categories identified by the LLM aligned closely with the responses provided by stakeholders. In addition to categorizing the insights, the LLM offered context for its decisions and highlighted the significance of each problem raised. A subsequent prompt was used to consolidate the information into seven primary problem categories. This allowed the data to be reduced without compromising quality, enabling quicker comparison with the participants' feedback. With the LLM's assistance and validation by participants, the following problem categories were established: 1. Function Plans of Companies; 2. Improvement of SEST Services;3. Processes and Analyses; 4. Challenges and Limitations; 5. Innovations and Tools; 6. Business Needs and Sustainability; and 7. Agility and Optimization. Moreover, leveraging the LLM's suggestions and further validation from participants, the core problem was defined as follows: *"The process of submitting and analyzing the function plan faces challenges related to the lack of agility, standardization, adequate information, and functionalities."*

Tab. 1 – Insights for the Functions Plan

ID	Insight
1	High demand volume: The process faces a large volume of requests.
2	Complex analysis: High quantity of documents requiring thorough review.
3	Merit analysis: Evaluation of the request's intrinsic merit.
4	Document analysis: Reviewing and validating submitted documents.
5	Order-based merit review: SEST technical merit analysis is conducted in the order of submission.
6	Document verification and checklist: Documents submitted by the supervising ministry are analyzed and checked.
7	Service automation: Automate the functions plan workflow to enhance user experiences for SEST, ministries, and state-owned enterprises.
8	Communication with supervisory authorities: Ensure effective communication within and outside the system.
9	Comparative analysis: Compare approved and proposed functions plans within the same state-owned enterprise and across others.
10	Initial submission: The process begins at the state-owned enterprise, which provides documents for analysis.

Continued on the next page

ID	Insight
11	Process agility: Accelerate the overall process to improve efficiency.
12	Guidelines and business context: Establish clear directives and align with organizational goals.
13	Technical note drafting: Prepare a technical note for review by coordinators and directors before approval by the secretariat.
14	Non-implementation of functions plan: Address instances where the enterprise fails to implement the plan.
15	Limited team: Small team available to handle the analyses.
16	Report generation: Extract reports of approved functions plans.
17	Document iteration: Revisions and resubmissions consume significant time.
18	System forms: Leverage system-based forms for data collection.
19	Procedural standardization: Establish a systematic approach to the process.
20	Legal basis review: Ensure the request adheres to legal requirements.
21	Largest requests: Prioritize significant or complex cases appropriately.
22	Improved SEST services: Enhance SEST's functions plan services for state-owned enterprises.
23	Proposal withdrawal or substitution: Determine whether ministries or enterprises can withdraw or replace proposals.
24	Modernization and simplification: Update and simplify regulatory frameworks.
25	Business needs: Address specific organizational requirements.
26	New functions plan proposals: Process new plan submissions effectively.
27	Final deliverable: Issue the technical note or official document to the state-owned enterprise.
28	Merit evaluation criteria: Define what aspects are considered in the merit analysis.
29	Reconsideration requests: Allow enterprises to submit reconsideration requests with SEST's response.
30	Functions plan scope: Evaluate and refine the functions plans of state-owned enterprises.
31	Process tracking: Enable access to the status of SEST processes.
32	Limited technical resources: Few technicians available to conduct analyses.
33	SEST role justification: Clarify why enterprises must undergo SEST's review process.
34	Information quality: Ensure accurate and comprehensive information is submitted.
35	Conditional responses: Provide responses with conditions, setting deadlines for the enterprise's reply to SEST.
36	Scope and approach review: Revise the scope and operational mode to align with goals for state-owned enterprises.
37	Alignment reviews: Use alignment sessions to complement information and enhance understanding.
38	Email communication challenges: Question the necessity of involving the supervising ministry when email suffices for enterprise communication.
39	Streamlining the process: Explore ways to make the process faster and more efficient.
40	Fast-track options: Consider "FAST-TRACK" workflows for groups of enterprises with similar characteristics.
41	Request complexity levels: Address the challenge of diverse complexity levels competing in the same workflow.
42	Risk supervision: Incorporate risk oversight mechanisms (e.g., Previc).
43	Financial sustainability: Ensure that plans are financially sustainable.
44	Participation scope: Clarify if all enterprises are required to submit these requests.
45	Transparency: Improve transparency by providing access to SEST's decisions and publishing timelines in official directives.
46	AI utilization: Implement AI tools to support analyses and decision-making.

Continued on the next page

ID	Insight
47	Excel and historical data: Use Excel spreadsheets to compare current requests with past proposals.
48	Enterprise versatility: Adapt to the unique characteristics of different enterprises.

In **the solution exploration phase**, after group discussions, participants identified the following critical points/contradictions: a) Compliance vs. User Guidance; b) Intelligent Automation vs. Analyst Replacement; c) Access Control vs. Transparency; d) Detailed Reporting vs. Merit Analysis; e) Process Standardization vs. Necessary Customization; and f) AI Usage for Analysis vs. Norm Review. Table 2 presents the results from applying the "Does" and "Does Not Do" technique. We asked the LLM to create a persona and a user journey representing an average Brazilian individual who uses the services presented during the workshop, focusing on the following information: Name, Age, Questions, Tasks, Feelings, Motivations, and Objectives. The LLM generated a persona that could potentially be used in the development of the workshop. However, the information was not directly presented to the group of participants. Instead, it was compared with the personas created by the participants themselves. During this comparison, some differences were identified, particularly concerning the "pain points" highlighted by more experienced stakeholders. Nevertheless, the prompt proved effective and has potential for improvements in future applications. To enhance the process, future iterations of the prompt should focus on prioritizing the "pain points" and "critical demands" raised by the participants, while maintaining the necessary randomness and divergence for problem exploration.

Tab. 2 – Solution Exploration with the Does and Does Not Do Technique

Does	Description
Receives and Categorizes Requests	Receives and categorizes user requests and processes.
Generates Reports	Provides detailed reports on the status and progress of requests.
Compliance	Assists in meeting norms and regulations.
User Guidance	Provides automated instructions and help to facilitate usage.
Uses AI for Analysis	Analyzes data using artificial intelligence, improving accuracy and efficiency.
Access Control and Security	Manages who can access specific information and functionalities.
Generates Indicators	Provides insights and performance metrics for users and managers.
Standardizes Requests	Defines a standardized workflow for handling different types of requests.
Intelligent Automation for UX	Automates processes to ensure a better user experience.
Communication and Integration	Serves as a bridge to connect information between systems and teams.
Provides Templates	Facilitates the creation and management of standardized documents.
Does Not Do	**Description**
Norms Review	Does not review or modify legal or regulatory norms.
Merit Analysis	Does not decide on the merit of issues; it only organizes the data.
Analyst Replacement	Does not replace human expertise or analysts' decisions.
Replicate Processes	Does not replicate processes without adaptations; it organizes but requires customization.
Generate Work	Does not create work automatically; it only manages and optimizes existing processes.

In **the User-Centered Redesign phase**, participants contributed to creating the persona profile. During the creation process, the workshop moderator facilitated discussions within each group, addressing their questions and providing any necessary information. Each group presented their persona's profile, including behavior and habits, pain points and frustrations, as well as needs and goals. Figure 1 illustrates the persona proposed by Group 1. We kept the image in Portuguese to preserve the authenticity and reliability of the content created during the workshop. The final persona profile was developed after extensive discussions and

comparisons of the proposals presented by all groups. The consolidated persona profile is detailed in Table 3. The first day of the workshop concluded with the definition of the persona's profile and behavior.

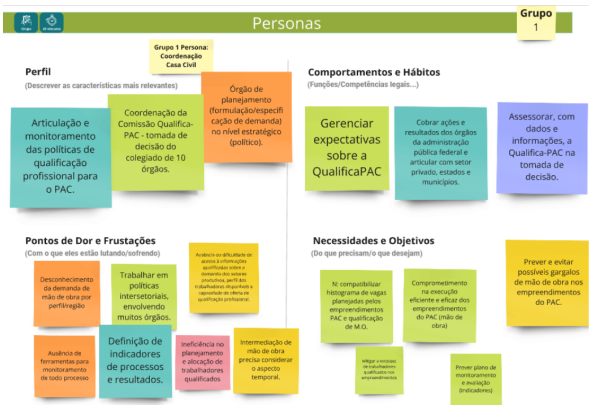

Fig. 1 – Persona Construction

Tab. 3 – Persona Profile/Behavior

Profile	Behaviors	Pain Points and Frustrations	Needs and Goals
SEST Analyst	Adds requested information, Analyzes personal files, Maintains financial health, Makes automated decisions.	Lack of understanding of requests, Incorrect demands, Distrust, Work overload.	More data and inputs, Clearer requests, Simplified communication with the company.
State-Owned Enterprise Career Analyst	Enjoys talking and discussing ideas, Promotes solutions, Open to change, Motivated by challenges.	Issues with expenses, Lack of subsidies, Conflicts of interest, Union pressures.	Autonomy in HR management, Quick information, Agility in proposal creation.
HR Manager (People Management)	Liaises with top management and SEST, Negotiates with unions.	Lack of understanding of SEST's demands, Slow analysis process.	Clear guidance, Agility, Fewer barriers in the process.
HR Competence Unit	Sense of urgency.	Delayed responses, Lack of guidance, Communication difficulties.	Faster responses, Greater autonomy, Easy-to-use and guiding system.
Public Enterprise	10,000 employees, Treasury-dependent, Aviation sector: Renewable energy production, Medium-sized company, Activation zone, Average budget.	Promotes renewable energy projects across the country, Oversees project implementation and execution, Manages federal funds allocated for its activities, Supports sustainable development in Brazil.	Lack of autonomy for independent work, Difficulty obtaining market benchmarks, Challenges filling specific roles, Incompatibility between public administration response times and market dynamics, Lack of understanding of technological evolution by SEST.

The second day of the workshop began with the definition of user journeys (**Phase: Journey-Based Functionality Design**. A total of four journeys were created: 1) Management of Job Plans; 2) Request for a New Plan; 3) Login and Plan Management via Gov.br; and 4) Process of Transfers and Plan Execution. This generic user journey integrates the main steps outlined in the four specific journeys, organizing the flow cohesively: Access and Login; Classification and Completion of the Request; Submission and Validation; Monitoring and Alerts; Completion and Notification; and Process Finalization with Accountability. It adheres to the primary

Tab. 4 – Generic User Journey

Step	Description
1. Access the System	The user accesses the system based on their profile (e.g., Gov.br system or the company's corporate system). They log in and select the type of request to be made (e.g., job plan, workload, remunerations, etc.).
2. Define the Request	The user classifies the request: it can be a new plan, an amendment to an existing plan, a reconsideration of a decision, or compliance with specific conditions. The system provides the option to consult a checklist or tailored instructions for each type of request.
3. Fill Out and Submit the Request	The user completes a smart template provided by the system, including clauses related to the request, such as: i) Remuneration value; ii) Specific assignments (e.g., FG, workloads); iii) Access requirements for the role; iv) Workload estimation; and v) General/thematic justification for the request. The system allows the inclusion of attachments and document validation before submission. After completing the template, the user submits the request, generating a protocol.
4. Validate and Forward the Request	The system performs automatic document validation. The request goes through internal reviews (e.g., legal, councils, IT, etc., as necessary). The user can forward the request to the supervising ministry or another competent authority, including a technical opinion, if applicable.
5. Monitor the Request	The user can check the real-time status of the request, accessing all company submissions via a dashboard. The system generates automatic alerts about deadlines, updates, or the need for additional adjustments. The user has access to the history of completed analyses and can track pending and new requests.
6. Conclude the Request and Notify the Supervising Ministry	The request is automatically finalized in the system, and the final document is made available to the user. The system automatically notifies the supervising ministry or competent authority of the decision regarding the request. If applicable, payment guides (e.g., GRU) or other types of documentation are generated.
7. Close the Process	The process is concluded with the implementation of the plan or the accountability procedure. The system records all stages, ensuring transparency and traceability. Control bodies can access the data to monitor and oversee the execution of planned actions.

stages, such as request classification, template completion, and document submission, enabling the execution of each type of plan or function within the system.

The Prototype Development phase was conducted using storyboards, which allow illustrating user interaction with the service. Each group created their wireframes using flip-charts, post-its and colored pens. Afterwards, all groups presented their results and collaborated to define the final unified version of the prototype. Afterwards, the solution screens were designed by design professionals, using the Figma tool. In **the Deliverables phase**, the MVP was developed, including the following elements: 1. Value Proposition: A concise description of the value the MVP will provide to users, focusing on the primary pain point or need it will address; 2. Personas: Identifies and describes the main user profiles of the MVP, including relevant characteristics, needs, and behaviors; 3. Journeys: Outlines the key steps a user will take when interacting with the MVP, focusing on the most critical interactions to deliver value; 4. Features: Lists the essential features the MVP must have, prioritizing only what is necessary to validate the main hypothesis; 5. Expected Outcomes (Prototypes): Describes the results expected from the MVP, including both business and user outcomes; 6. Metrics: Defines the key metrics that will be used to measure the success of the MVP, ensuring they align with the expected outcomes; 7. Cost and Timeline: Estimates the total cost to develop and launch the MVP, creating a high-level timeline with key stages and deadlines; and 8 Delivery Date: Sets a clear delivery date for the MVP, helping to maintain focus and prevent scope creep.

These components serve as the foundation for developing the MVP, ensuring a focused, result-driven approach that allows for quick adjustments as needed. In **the Evaluation phase**, the methodology was assessed through participant feedback, the quality of the MVP, and the overall efficiency of the workshop process. The evaluation

focused on metrics such as the time spent on each stage, the effectiveness of integrating LLMs, and how well the final prototype aligned with user and organizational needs. This feedback provided valuable insights for refining the methodology and improving future workshops.

The results of the Service Design workshop, Startup EstataisGov, provided an overview of the management and submission process for job plans in state-owned enterprises. It highlighted the main process stages and the challenges faced by public servants in these organizations. The proposed solution was developed through participant insights, presentations, and prototyping activities. The narrative focused on enhancing efficiency, transparency, and innovation in addressing the activities and challenges of the job plan process. Over the two-day workshop, several critical areas for improvement were identified, particularly the lack of standardization and speed in handling requests, as well as the need for more effective communication between state-owned enterprises and SEST. Workflow analysis emphasized how automating certain process steps could reduce response times while ensuring a better user experience. The use of generative AI across all stages helped improve the quality of analyses and discussions, ensuring responses were faster and more accurate. Thus, the outcomes achieved during the workshop were highly positive, providing a clear roadmap of current issues and challenges, as well as practical and innovative solutions. The focus on digital solutions, standardization, user experience, and the adoption of new technologies aims to create a significant positive impact on the efficiency and transparency of the job plan management process in state-owned enterprises. These results paved the way for a more agile, integrated, and effective system, capable of meeting the demands of state-owned enterprises and supervising ministries while ensuring compliance with current regulations and accelerating processes.

RQ.1 Summary: A fast track for collaborative solutions supported by Large Language Models (LLMs) can optimize design workshops in public service by automating repetitive tasks, such as data categorization and summarization, enhancing real-time collaboration, and providing instant access to relevant information. LLMs can facilitate idea generation and decision-making by analyzing vast amounts of textual data and identifying key patterns. This reduces time spent on manual processing, allowing participants to focus on high-value activities. Moreover, the integration of LLMs can improve communication and alignment between stakeholders by ensuring consistency and clarity in the shared content.

5. Discussions

This section highlights several critical challenges identified within public service workflows, including process inefficiencies, high demand and limited resources, inadequate communication, and lack of transparency. These challenges are not exclusive to this study but are consistent with those reported in other research on public sector operations. **Process Inefficiencies**: The workflow for analyzing public service plans is hindered by bureaucratic delays, lack of standardized templates, and high variability in submission quality. Participants highlighted the prolonged timelines required for document verification, merit analysis, and internal reviews. Other studies have similarly highlighted inefficiencies in governmental decision-making processes, often attributed to bureaucratic complexities (Eom & Lee, 2022; Harfianto et al., 2022).

High Demand and Limited Resources: SEST faces an overwhelming volume of requests with a limited number of technical analysts. This imbalance often results in delays and bottlenecks, especially for complex submissions. (Daßler et al., 2024) conducted 17 expert interviews to investigate the co-production process, the measures utilized, and the challenges faced. Four key challenges were identified: recruiting citizens, managing resources, navigating political hurdles, and fostering cooperation between administration and citizens. The study also highlighted that financial constraints are a common issue in collaborative projects involving citizens, with personnel shortages presenting a significant challenge. The authors emphasize the importance of adequate budgets and professional facilitation to ensure the sustainability of projects and their efficient implementation by public agencies. **Inadequate Communication**: Communication gaps between public enterprises, supervisory ministries, and SEST were noted as a major issue. Misaligned expectations and unclear guidelines exacerbate these challenges. This finding aligns with other studies in the literature (**DBLP:journals/jucs/MarsicanoCPRF24**; Androniceanu, 2021; Canedo et al., 2021; Criado & Villodre, 2022; Daßler et al., 2024; Figueiredo, Venson, et al., 2024; Venson et al., 2024), which also highlight challenges stemming from communication difficulties, particularly in maintaining consistent citizen engagement, managing diverse stakeholder interests, and aligning differing schedules.

Lack of Transparency: Stakeholders identified the need for greater visibility into the status of submissions and decisions, emphasizing that a transparent process would build trust and accountability. (Androniceanu, 2021) investigated the level of transparency in Romanian government ministries by analyzing public data and information available on the websites of 18 ministries and conducting online surveys with 45 employees from the ministries' Information and Documentation Departments. The authors concluded that administrative transparency remains a challenge for Romanian government ministries. They emphasized that access to information builds citizen trust in public agencies, enables citizens to understand government decisions, and increases their confidence and satisfaction in using public services offered by the government. This finding reinforces the results of our research. Despite identifying some challenges during the public service design workshops supported by LLMs, several key advantages were observed: **1) Time Reduction**: The implementation of the Fast Track reduced the duration of workshops by at least 30%; **2) Improved Collaboration**: Enhanced participant engagement driven by the agility and clarity of the process; and **3) More Informed Decisions**: The effective consolidation of ideas resulted in stronger and more robust proposals. The facilitation of the workshop enabled greater efficiency in handling large volumes of information and reduced fatigue during extended collaborative processes, given that the processes analyzed by SEST are complex and require the involvement of various stakeholders. However, the reliance on certain tools and the need for adequate infrastructure to conduct the workshop, as well as challenges in participants' initial adaptation to the tools used, may impose limitations on the use of the fast track for collaborative solutions. Despite these limitations, the proposed methodology for conducting workshops has the potential to transform the way workshops with Brazilian federal public administration agencies are conducted in the public sector, fostering agile and collaborative decision-making among all participants. Furthermore, the fast track can be adapted to any public service in different countries.

6. Threats to Validity

In this study, several potential threats to validity have been identified, which may influence the reliability and generalizability of the results. Following the framework of Wohlin et al. (2012), these threats can be categorized into internal, construct, external, and conclusion validity. **Internal validity** refers to the extent to which the study can establish causal relationships between the interventions (for instance, the use of AI and automation) and the outcomes (for example, efficiency improvements, decision quality). A potential threat to internal validity could be the presence of uncontrolled variables, such as external organizational changes or variations in the level of experience of the participants (for instance, technicians and managers). Additionally, biases in the selection of participants or sample sizes could influence the observed outcomes. Efforts were made to mitigate this threat by involving a diverse set of participants from various roles within the public sector companies, ensuring a broader understanding of the system's impact.

Construct validity concerns whether the measures used in the study truly represent the concepts they are intended to measure. In this study, the main constructs include process efficiency, decision quality, and user satisfaction. A potential threat is the use of subjective assessments (for instance, user feedback) to evaluate these constructs, as different participants may interpret or report their experiences differently. To mitigate this, multiple sources of data were used, including surveys, interviews, and system logs, which helped triangulate the findings and reduce the bias associated with any single source. **External validity** concerns the generalizability of the findings beyond the specific context of the study. One potential threat is that the results may not be applicable to all public sector agencies or to other governmental systems that do not use similar technologies. The study was conducted in a specific setting (state-owned companies and focused on a particular process: Function Plan). As such, caution must be exercised when generalizing the findings to other contexts. Future studies in different sectors or with larger sample sizes could help improve external validity and expand the generalizability of the results. **Conclusion validity** concerns the degree to which the conclusions drawn from the study are accurate and reliable. A possible threat to conclusion validity is the improper use of analysis, which could lead to false positive or negative results. To address this, appropriate methods were applied to analyze the data, ensuring that the results were statistically significant and reflective of the true impact of AI and automation. However, limitations in the sample size and study duration could still affect the robustness of the conclusions. Future research should focus on expanding the scope of this study, potentially involving a larger and more diverse set of public sector organizations, as well as incorporating longitudinal data to assess the long-term effects of AI and automation on process efficiency, decision quality, and user satisfaction. Additionally, further studies could explore the impact of different AI models and automation technologies on the outcomes of the process, ensuring the reliability and robustness of the findings across different contexts.

7. Conclusions

The workshop outcomes provided valuable insights into the existing challenges and opportunities for improving the management of job plans in state-owned enterprises and the SEST. The comprehensive mapping of problems revealed key issues such as delays in the analysis process, lack of standardization in documentation, and complex workflows, all of which were hindering the efficiency of the system. These findings formed the foundation for proposing practical solutions to streamline and optimize the entire process. The development of user journeys provided a deeper understanding of the different user interactions with the system. By mapping out the steps for various types of demands—such as new plans, modifications, reconsiderations, and compliance requests—participants were able to identify critical touchpoints that require optimization for improved user experience and efficiency.

Prototyping and refining system functionalities were crucial to visualizing the potential improvements, such as the use of intelligent templates, workflow automation, and automated report generation. These prototypes not only allowed for the testing and validation of ideas but also laid out a clearer path for future system implementation. The consensus around integrating advanced technologies, particularly automation and AI, was a pivotal outcome. Participants identified that automating document analysis and demand tracking could significantly reduce the time required for merit evaluations, enabling SEST technicians to focus on more complex tasks. This would also improve the accuracy and consistency of the analysis process, minimizing errors and rework. Standardization emerged as a central theme, aiming to unify demand management with clear workflows and standardized models. This approach is intended to simplify tasks for both technical staff and managers, while enhancing transparency throughout the process. It would also create a more predictable workflow, allowing for better expectations management for both state-owned enterprises and supervising ministries. Furthermore, the focus on improving user experience (UX) underscored the importance of creating an intuitive, accessible, and adaptable system that caters to the diverse needs of different user profiles. This not only involves system interface design but also emphasizes real-time communication and information sharing between all parties involved.

Several innovative ideas and simplifications were proposed, including the creation of a FAST-TRACK for less complex demands and the modernization of the regulations governing job plan processes. Simplifying workflows and granting greater autonomy to state-owned enterprises were seen as necessary measures to address the growing volume of demands. These innovations align with the need to ensure the sustainability of the process and its compliance with government policies and business directives. In conclusion, the workshop successfully provided a roadmap for creating a more efficient, transparent, and user-centered system for managing job plans in state-owned enterprises. The integration of technology, standardization, and user-focused solutions offers a promising path toward improving process efficiency and ensuring compliance with regulatory requirements. Considering the fundamental role of artificial intelligence and automation in improving the organizational efficiency of public sector companies, a future study should focus on evaluating the real impact of generative AI. This should not only include the operational efficiency of processes but also assess the impact on the quality of decisions made by technicians and managers in state-owned companies. Furthermore, it is important to evaluate the accuracy of automated analyses and how this affects the satisfaction and trust of users in government systems.

Acknowledgments

Submitted: 31 January 2025, Revised: 26 March 2025, Accepted: 21 April 2025, Published: 21 May 2025

Abstract. Gamification may foster citizen relationships with the government but can also result in a disinterest in participation. In the context of digital government, we do not know which game elements specifically contribute to citizen engagement. In this paper, we conduct an integrative study, drawing from existing literature on citizen engagement through gamification. We examined the citizens' motivation to engage with the government, linked it with game elements explored in the literature, and finally exhibited how these elements could support or inhibit citizens' motivation. Using self-concordance and civic engagement models, we investigated gamification focusing on individual experiences, both personally and as citizens. The findings of this research show a link of static game elements with external and introjected forms of motivation. In contrast, dynamic game elements seem more aligned with intrinsic and identified motivation. We develop a taxonomy outlining these relationships, enabling further research on game elements and their impact on citizen engagement over time.

1. Introduction

Involving citizens in government activities and encouraging their engagement leads to successful collective action (Firmstone & Coleman, 2015; Graham et al., 2019; Kaur et al., 2022). This engagement promotes inclusivity, addresses inequalities, and attracts citizens' interest and opportunities (Arndt et al., 2020; Lopez et al., 2024). However, in the context of digital government, traditional methods such as town hall meetings and public hearings are struggling to engage citizens effectively (Fung, 2015; Irvin & Stansbury, 2004; Kumagai & Ilorio, 2020). The main challenge is making information and opportunities accessible and enjoyable for everyone (Balestrini et al., 2017; Fung, 2015; Purwanto et al., 2020). Digital technologies offer promising solutions to this issue (Firmstone & Coleman, 2015; Geiselhart, 2004; Haro-de-Rosario et al., 2018; Mossberger et al., 2007).

Building on the potential of digital technologies to increase citizen engagement, gamification has emerged as an innovative approach in the digital government context (Van Zoonen, 2020). Gamification has been used to boost citizen participation in activities such as urban planning, public policy feedback, and civic involvement (Hassan & Hamari, 2019; Kazhamiakin et al., 2015; Schrape, 2014). Gamification makes government processes more

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

interactive and enjoyable, thus increasing engagement (Bianchini et al., 2016; Hassan, 2017; Hassan & Hamari, 2019). However, it also risks shallow engagement and may not sustain long-term involvement (Hassan et al., 2018; Raftopoulos, 2020; Steffens et al., 2017).

Given these factors, it is essential to understand the game elements that make gamification work. For example, the Mechanics, Dynamics, and Aesthetics framework defines a game's mechanics as rules, dynamics as user behavior, and aesthetics as emotional responses (Hunicke et al., 2004). Other definition focuses on motivation, goal completion, and engagement (García Iruela et al., 2019), while another delves into motivation-focused components such as flow, relatedness, purpose, autonomy, and mastery (AlMarshedi et al., 2014). Despite multiple definitions, there remains a notable lack of comprehensive overviews specifically detailing how these elements influence citizen engagement in government activities. This gap is also noted by Resek et al. (2024) and Contreras-Espinosa & Blanco-M (2022). Without a clear understanding of these elements, governments and researchers may struggle to engage citizens effectively using gamification.

This paper bridges the gap by establishing a taxonomy of these elements. We aim to open new avenues for research into citizen engagement and contribute to educational technology by providing insights into how gamification can be effectively applied in civic contexts. Academically, this study contributes to the digital government and participation literature by identifying game elements that influence citizens' engagement in government activities. Practically, it provides insights for governments on using gamification to increase citizen engagement.

In addressing these objectives, we develop a protocol to direct our study. First, we focus on understanding the motivations of citizens to participate in gamified citizens' engagement, both personal and civic motivations. Then, we examine the drivers and barriers that influence their participation. Finally, we explore the game elements that bridge these motivations, drivers, and barriers, providing a comprehensive taxonomy of game elements enabling citizens' engagement.

To present these insights effectively, this study is structured as follows: the research approach, findings, discussion, and conclusions.

2. Research Approach

This paper systematically integrates studies on game elements for citizen engagement using the PRISMA protocol due to its structured and transparent approach (Moher et al., 2009). To complement this approach, we use backwards and forward snowballing (Wohlin, 2014) and materials from Scopus and Web of Science. Then, we discuss the findings with prior studies to reflect on existing knowledge and further contextualize our results within the broader literature.

To guide our study, we formulate three research questions:

RQ1: What motivates citizens to participate in gamified citizen engagement initiatives within digital government?
RQ2: What factors enable or hinder citizen participation in gamified digital government platforms?
RQ3: What are the game elements for gamifying citizen engagement in digital government contexts?

Our search protocol follows the PRISMA phases: identification, screening, eligibility, and inclusion. In the first phase, identification, we use Scopus and Web of Science databases since they are both widely recognized databases for academic literature (Martín-Martín et al., 2018). The search strings in titles and abstracts consist of four sets of keywords: gamification, factors, interaction, and stakeholders, as depicted in Tab. 1. We include "participation" and "engagement" since they are often used interchangeably to describe citizens' involvement. Specific strings in gamification, interaction, and stakeholder sets must exist in the articles' keywords to narrow the search to gamification in government. The publication language is English because studies suggest no evidence of systematic bias in using only English (Jüni et al., 2002; Morrison et al., 2012). We limit the start year of publication to 2010 because it marks the first appearance of the word "gamification" in Google Trends (Google, 2024). During the second phase, screening, we eliminate studies that are not pertinent to the research issue. In the third phase, eligibility, we thoroughly evaluate the remaining research for their relevance and quality. Studies that do not correspond with the research aims are excluded. The rationale for exclusion is recorded to guarantee openness. In the final phase, inclusion, studies that satisfied all inclusion criteria are incorporated into the review. This phase involved a detailed examination of the selected studies to extract relevant data on the gamified citizens' engagement.

For the backward search, we include articles authored by similar researchers within the context of gamification in citizen engagement. For the forward search, we include subsequent articles citing the current article that also focused on gamification in citizen engagement. Our inclusion criteria require that the title or abstract addresses gamification in government settings and that the article's content pertains to citizen engagement. Conversely, articles failing to meet these criteria are excluded.

We conducted our search in May 2024. Initially, we found 117 studies: 96 from Scopus and 21 from WoS, resulting in 99 papers after removing duplicates. In the screening, eligibility, and inclusion phases, we included 3 studies from backward and forward searches and excluded 24, totaling 78 studies consisting of conference papers, articles, and book chapters from 2011-2024. Our reason for exclusion is that the study should relate to citizens' engagement. The overall process is outlined in Figure 1.

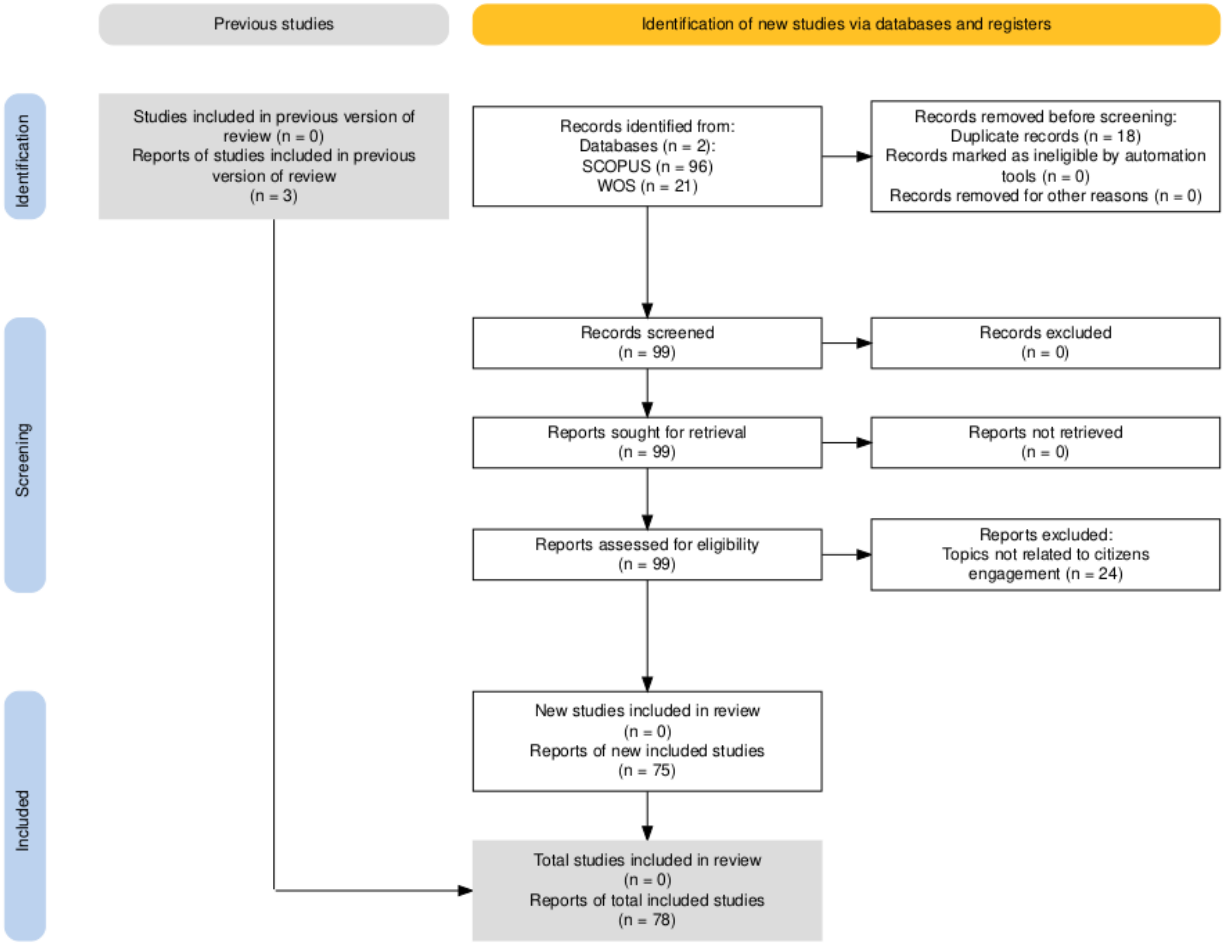

Fig. 1 - PRISMA flow diagram of citizens' motivation, drivers, and barriers of gamified citizens' engagement. This diagram was created using an online PRISMA flow diagram (Haddaway et al., 2022).

3. Findings

This section is structured based on the general findings and the research questions formulated to guide this study. First, we present the bibliometric analysis and notable discoveries. Then, we report the findings on citizens' motivations to engage, which explore individual and civic motivations. Next, we analyze the drivers and barriers of gamification, examining how these aspects influence engagement within civic contexts. Finally, we examine the game elements found in the literature. By organizing the findings in this way, we aim to provide comprehensive information before we discuss their relationship in the next section.

3.1 Bibliometric analysis

In this subsection, we examine the type of publication to understand the distribution across journals, conference papers, and book chapters. Then, we analyze the year of publication to identify the trends of studies in this context. Next, we explore the author's keywords to uncover focus areas within the literature. Finally, we assess the types of games discussed in the papers, providing insights into the specific gamification approaches applied to citizen engagement.

Over 90% of gamification studies in citizen engagement are in conference papers and articles, with few in book chapters. The limited number of studies on gamification in citizen engagement disseminated through book chapters indicates an underutilization of this publication format. This gap suggests an opportunity for researchers to explore the potential of book chapters to provide a more comprehensive analysis and to reach diverse academic audiences.

Examining the year of publication shows growing studies from 2011, a plateau since 2018, and a spike in 2023. This number indicates an ongoing discussion of gamification research since 2018 and a growing interest in recent years. The low number of publications in 2024 may be attributed to ongoing research that has yet to reach publication stages.

We notice the "science" keyword occurs often in the literature search. Further analysis showed that the "science" keyword relates to studies referencing citizen science, where gamification can help the public to contribute to collecting or analyzing the data for research (Haklay et al., 2021). In the assessment of the type of game discussed in the study, we find that 13% of the searched literature discusses evolutionary game theory (EGT), which combines evolutionary biology with game theory (Sigmund & Nowak, 1999). This type of study, funded by Chinese institutions, led to increased research in 2023. Although loosely related to gamification, EGT's focus on stakeholder motivation and interest is similar to gamification's focus, therefore we keep it for further analysis.

3.2 Citizens' motivations

Investigating citizens' motivations reveals why they choose to participate in gamified citizens' engagement. To explore these motivations in depth, we employ the Self-Concordance Model which helps differentiate between individual motivations rooted in personal goals and values, and the Civic Engagement Model which distinguishes civic motivations shaped by resources, psychological engagement, and community.

The Self-Concordance Model classifies motivation into four types: external, introjected, identified, and intrinsic (Sheldon & Elliot, 1999). External motivation, driven by outside factors, includes in-game items like Geo-coins that lead to real-world incentives (Clarke et al., 2017), recognition through scores and badges (Gicquel et al., 2019), or penalties for prolonged silences in recordings (Hantke et al., 2018). Introjected motivation is an internalized form of motivation where goals serve to maintain a certain self-image, such as a sense of ownership for cooperating in Citizen Social Lab (Vicens et al., 2018). Identified motivation occurs when goals are personally significant and driven by personal values, exemplified by users' team preferences in MTV Fantasy Election (Foxman & Forelle, 2014). Intrinsic motivation involves pursuing goals for enjoyment or stimulation as the joy users find in completing OldWeather (Eveleigh et al., 2013) or the immersive experience of Forgotten Island (N. Prestopnik & Souid, 2013). These motivations align with an individual's core values, therefore they are essential for understanding the outcomes of gamification.

The Civic Engagement Model explains citizen participation in government activities through three components: resources, psychological engagement, and recruitment networks (Verba et al., 1995). Resources refer to the necessity for citizens to have spare time, financial means, or skills to participate in gamified citizen engagement. For example, the lack of digital skills among the elderly can hinder their participation in gamification systems (Mendez et al., 2019). Psychological engagement involves the motivation driving citizens to engage psychologically in gamified citizen participation. An example is the narrative element of the Climate4Kids app, where the character Mani helps create an emotional connection, making the topic more relatable and motivating children to take action (Gabriel & Schmölzer, 2022). Recruitment networks refer to the ability of citizens engaged in gamified activities to attract others to join. For instance, citizen involvement in Community Planit led to greater engagement and support

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

for initiatives (Hassan & Hamari, 2020). These factors reveal potential motivators for citizens and can be used to maintain their engagement.

3.3 Drivers and barriers to citizen participation

We explore the aspect of engagement to see why gamification in civic activities appeals to citizens. Seven driving factors are identified, as outlined in Tab. 2. Five relate to individual motivation: 1) Gamification enhances motivation by making activities enjoyable and rewarding. 2) Autonomy and control give citizens power over the system, boosting engagement. 3) Personalized experiences meet citizens' needs and interests, keeping them engaged. 4) Clear goals and progress provide a sense of transparency and achievement. Finally, 5) Challenges encourage mastery and a sense of completion. The other two are related to social dynamics: 6) A sense of community is created through multiplayer features or leaderboards, encouraging participation. Lastly, 7) competitions ignite motivation for showing skills and long term engagement.

To understand why some gamification failed, we investigate barriers to gamification from its design and external conditions. Ten barriers are identified, four related to design: 1) Focusing too much on extrinsic rewards can reduce engagement. 2) Intense competition and rewards may dampen intrinsic motivation. 3) Poor user interface leads to difficulty in participating effectively. Lastly, 4) Poor gamification mechanisms can reduce engagement. The other six barriers are related to external factors: 5) Skepticism leads to distrust and difficulty in attracting users. 6) Economic barriers may prevent low-income participation. 7) Socio-cultural factors can hinder engagement in specific demographics. 8) Privacy concerns can deter participation if not handled correctly. 9) Limited feedback or support makes citizens refrain from gamification. Finally, 10) technology overload can overwhelm and disengage citizens.

More studies report on the drivers of gamification than on its barriers. This suggests researchers focus more on the positive outcomes than the drawbacks. These differences show the current state of gamification research and highlight the need for future studies to examine both aspects.

Tab. 2 - Drivers and barriers to citizens' participation with detailed information in Appendix A and B (in supplemental material)

Drivers	Number of studies	Barriers	Number of studies
Enhancing personal motivation	52	Overemphasis on external rewards	5
Autonomy and control	10	Dampened intrinsic motivation	1
Personalized experiences	7	Poor user interface	1
Transparent goals and progress	19	Poor gamification mechanism	2
Sense of community	23	Skepticism	4
Challenges	17	Economic barriers	1
Competitions	27	Socio-cultural factors	1
		Privacy concerns	3
		Limited feedback or support	1
		Technology barriers	4

3.4 Game elements in the literature

The literature provides examples of different types of games, namely serious games, commercial games, and gamification. Serious games are designed for educational purposes or to change behavior, not just for entertainment, focusing on user experience and achieving real-world outcomes (Abt, 1975; Michael & Chen, 2011). Commercial games, by contrast, aim purely to entertain, concentrating on engaging gameplay, graphics, and storytelling to generate profit (Wolf, 2002). Gamification applies game elements to non-gaming contexts to increase engagement (Deterding et al., 2011). Although these categories differ in purpose, they all share the common use of game elements to achieve their objectives.

To better identify these game elements, we classify them into static and dynamic, as outlined in Tab. 3. Static elements are predefined components such as features or metrics. Dynamic elements are the processes that interact with static elements. For example, points and ranks are static, while the difficulty of earning those points and ranks is dynamic.

Tab. 3 – The game elements with detailed information in Appendix C and D (in supplemental material)

Static Elements	Number of studies	Dynamic Elements	Number of studies
Points/Scores	37	Progress	22
Badges/Achievements	21	Aesthetics	4
Leaderboards	27	Ease of use	2
Levels/Ranks	21	Challenges/Difficulties	13
Rewards/Bonuses/Prizes	30	Rarity	3
Punishments/Penalties	12	Competition/Cooperation	24
Avatars	5	Narrative/Themes/Plots/Story	17
Virtual Goods/Collections	3	Feedback	27
Virtual currencies	3	Discovery	2
Tutorials	2	Social Interaction	19

Further delving into the static and dynamic elements, we explore each element and then connect each to the motivation, drivers, and barriers as reported or implied in the literature. We summarize our findings of static game elements in Tab. 4 and the findings of dynamic game elements in Tab. 5.

Tab. 4 – Taxonomy of static game elements

Game Elements	Individual Motivation	Citizen Motivation	Drivers	Barriers
Points/Scores	External	Resources	Enhancing motivation	Overemphasis on extrinsic rewards
Badges/Achievements	• External • Introjected	• Resources • Recruitment Networks	• Enhancing motivation • Personalized experiences	• Overemphasis on extrinsic rewards • Poor UI • Poor mechanism
Leaderboards	• External • Introjected	• Resources • Recruitment Networks	• Enhancing motivation • Challenges • Competitions	• Overemphasis on extrinsic rewards • Privacy concerns
Levels/Ranks	• External • Introjected	Resources	Enhancing motivation	Overemphasis on extrinsic rewards
Rewards/Bonuses/Prizes	External	• Resources • Psychological Engagement • Recruitment Networks	Enhancing motivation	• Overemphasis on extrinsic rewards • Poor mechanism
Punishments/Penalties	External	• Psychological Engagement • Recruitment Networks	• Enhancing motivation • Challenges	Overemphasis on extrinsic rewards
Avatars	Introjected	Psychological Engagement	Personalized experiences	Poor UI
Virtual Goods/Collections	External	• Resources • Recruitment Networks	• Enhancing motivation • Personalized experience	• Overemphasis on extrinsic rewards • Poor mechanism
Virtual currencies	External	• Resources • Psychological Engagement	Enhancing motivation	Overemphasis on extrinsic rewards
Tutorials	External	Resources	Autonomy or control	• Poor UI • Skepticism

Points or scores are widely used to measure users based on actions, serving as motivational tools for rewards and engagement (Hassan, 2017). For example, users might use mobile esports to compete, win, or even earn monetary

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

rewards, indicating that investing skills and time are required for participation (Hassan & Hamari, 2020; Vanolo, 2019). While points can boost engagement, relying too much on them without other rewards risks losing participation over time (Foxman & Forelle, 2014; Hassan & Hamari, 2020; Peischl et al., 2014; N. R. Prestopnik & Tang, 2015; Resek et al., 2024).

Badges or achievements indicate that users have met a game's objectives (Hassan, 2017). They seem to influence external motivation and drive introjected motivation, serving as proof of success and encouraging other users' participation (Bhéreur-Lagounaris, 2016; Bowser et al., 2014; Clarke et al., 2017; Gabriel & Schmölzer, 2022; Gastil & Broghammer, 2021; Gicquel et al., 2019; Hantke et al., 2018; Iacovides et al., 2013; Mendez et al., 2019; Peischl et al., 2014; Rehm et al., 2018; Sergeyeva et al., 2020). However, obtaining them requires citizens to invest time, money, or skills (Becker et al., 2019; Clarke et al., 2017; Dargan & Evequoz, 2015; De Francisco et al., 2024; Gastil, 2023; Gastil & Broghammer, 2021; Hantke et al., 2018; Mendez et al., 2019). Badges can boost engagement and offer personalized experiences, however, overemphasizing their extrinsic rewards and their poor user interface or gamification mechanism may disengage users (Dargan & Evequoz, 2015; Mendez et al., 2019).

Leaderboards rank users based on their points or achievements (Hassan, 2017). Similar to badges, leaderboards seem to provide external motivation and can be proof of success to others, but acquiring them requires an investment of resources (Bousios et al., 2017; Hassan & Hamari, 2020; Torres-Toukoumidis et al., 2017). Although leaderboards increase motivation and offer challenges or competitions, excessive rewards and privacy concerns may deter engagement (Foxman & Forelle, 2014; Gastil, 2023; Hassan, 2017; Hassan & Hamari, 2020; Moreira et al., 2020; Peischl et al., 2014; Torres-Toukoumidis et al., 2017; Vanolo, 2019).

Levels or ranks show a user's progression or challenges in a game, such as in "Papers, Please," which uses days as levels (Pflanzl et al., 2017). Levels seem to affect external and introjected motivation, but they need an investment of time, cost, or skills (Avolicino et al., 2022; Bousios et al., 2017; Fernandes & Junior, 2016; Hantke et al., 2018; Padilla-Zea et al., 2022; Torres-Toukoumidis et al., 2017). Although levels enhance motivation, excessive rewards might disengage users (Eveleigh et al., 2013; Gicquel et al., 2019; Palacin-Silva et al., 2018; Thiel, 2015; Thiel et al., 2016).

Rewards, bonuses, or prizes are given to users for completing game challenges and can be virtual or real-world rewards, such as currency or other in-game benefits, as seen in Forgotten Island (N. R. Prestopnik & Tang, 2015). Rewards seem to be linked to external motivation and can influence psychological engagement, as well as encourage others to join, but they need resources to invest (Bhéreur-Lagounaris, 2016; Lee et al., 2017; Schell & Kaufman, 2016; Wilis & Parningotan Manik, 2022). However, poorly designed and too much focus on extrinsic rewards can hinder engagement (Bu et al., 2023; Clarke et al., 2017; Foxman & Forelle, 2014; Hassan & Hamari, 2020; Thiel & Lehner, 2015).

Unlike rewards, **punishments or penalties** impose negative consequences on users who do not meet objectives. For example, penalties in evolutionary game theory promote green innovation and enforce driving regulations (Sun et al., 2023; Wang et al., 2021). They seem to motivate psychologically and encourage others to join, but they require an investment of resources (Sun et al., 2023). Punishments present challenges, but excessive rewards from punishments may deter engagement (Li et al., 2023).

Avatars, visual representations of users, provide a sense of presence or personality within a game, such as avatars in EcoGo (Avolicino et al., 2022). Avatars can serve as proof of success and seem to provide psychological motivation (Avolicino et al., 2022; Resek et al., 2024; Thiel et al., 2016). They also provide a personalized experience, but poor interface may deter engagement (Thiel et al., 2016).

Virtual goods or collections, such as collectables in the iHEARu-PLAY game and in-game pets (Clarke et al., 2017; Hantke et al., 2018)(Clarke et al., 2017; Hantke et al., 2018), seem to be linked to external motivations and encourage the participation of others. However, they require an investment of resources (N. R. Prestopnik & Crowston, 2011). Virtual goods enhance the personalized experience, but excessive use and poor mechanisms may deter engagement (Clarke et al., 2017).

Virtual currency, such as GeoCoins or eco-points (Avolicino et al., 2022; Clarke et al., 2017), acts as in-game money to facilitate actions in the game. Virtual currency seems to tap external motivation and provide psychological motivation, but it requires an investment of resources (Clarke et al., 2017; Hantke et al., 2018; N. Prestopnik & Souid, 2013), and excessive use of it may disengage users (De Francisco et al., 2024).

Tutorials help users understand what they must do in a game, making it more approachable. They familiarize users with game mechanics, requiring an investment of time and skills, such as in The Climate Game or the Climate4Kids game (Torres-Toukoumidis et al., 2017; Vicens et al., 2018). Tutorials seem to provide a sense of autonomy and control, but a poor interface and skepticism can deter engagement (Schell & Kaufman, 2016; Torres-Toukoumidis et al., 2017).

Tab. 5 – Taxonomy of dynamic game elements

Game Elements	Individual Motivation	Citizen Motivation	Drivers	Barriers
Progress	Identified	• Resources • Psychological Engagement	• Autonomy or control • Clear goals or progress	• Poor UI • Poor mechanism
Aesthetics	Intrinsic	Psychological Engagement	• Enhancing motivation • Personalized experiences	• Socio-cultural factors • Technology overload • Poor UI
Ease of use	Intrinsic	Psychological Engagement	• Enhancing motivation • Personalized experiences	• Technology overload • Poor UI
Challenges/Difficulties	Intrinsic	• Resources • Psychological Engagement	Challenges	• Poor mechanism • Dampened intrinsic motivation
Rarity	Intrinsic	• Resources • Psychological Engagement • Recruitment Networks	• Enhancing motivation • Challenges	Dampened intrinsic motivation
Competition/Cooperation	• External • Introjected	• Resources • Psychological Engagement • Recruitment Networks	Competitions	• Poor mechanism • Skepticism
Narrative/Themes/Plots/ Story	Identified	• Psychological Engagement • Recruitment Networks	• Clear goals and progress • Personalized experiences	• Socio-cultural factors • Skepticism
Feedback	Identified	Psychological Engagement	• Enhancing motivation • Autonomy and control	• Limited feedback or support • Skepticism • Poor mechanism
Discovery	Intrinsic	• Resources • Psychological Engagement	• Autonomy and control • Personalized experiences	• Poor mechanism • Skepticism
Social Interaction	• Intrinsic • Identified	• Resources • Psychological Engagement • Recruitment Networks	• Enhancing motivation • Sense of community • Personalized experiences	• Privacy concerns • Socio-cultural factors • Poor mechanism

Progress tracks objectives achieved by users. For example, progress bars are used to break tasks into smaller goals, as seen in eCH-BPM Switzerland's approach (Dargan & Evequoz, 2015; Vanolo, 2019). Progress, motivated by personal value to finish the task, seems to be psychologically engaging but requires an investment of resources (Becker et al., 2019; N. Prestopnik & Souid, 2013). Citizens have autonomy and control over progress, but a poor UI or mechanism can deter engagement (Hassan & Nader, 2016; Moreira et al., 2020; Rehm et al., 2018).

Aesthetics, including visuals and sounds, influence a game's atmosphere and user engagement (De Francisco et al., 2024; Romero-Hernandez et al., 2018). They seem to provide intrinsic motivation and personal enjoyment, fostering psychological engagement (Clarke et al., 2017; Latifi et al., 2022). However, socio-cultural differences, technological limitations, and poor interface seem to deter participation (Hassan & Nader, 2016; Pflanzl et al., 2017; Quecke & Mariani, 2021).

Ease of use in gaming means features that simplify gameplay, such as user-friendly interfaces for the elderly, children, or people with (Bousios et al., 2017; Mendez et al., 2019; Schell & Kaufman, 2016). It links to intrinsic

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

motivation and psychological engagement (Minge et al., 2014; Schell & Kaufman, 2016). This game element personalizes the experience, but technological overload and a poor UI can deter engagement (Mendez et al., 2019; N. R. Prestopnik & Crowston, 2011; Redondo, Giménez, Navarro, & Fonseca, 2020; Schell & Kaufman, 2016; Vicens et al., 2018).

Challenges or difficulties in games make users overcome obstacles to reach goals. They provide intrinsic and psychological motivation but require an investment of time, money, or skills (Bhéreur-Lagounaris, 2016; Pflanzl et al., 2017; N. R. Prestopnik & Tang, 2015; Torres-Toukoumidis et al., 2017; Wilis & Parningotan Manik, 2022). Although the challenge element drives gamification, a poor challenge mechanism can deter engagement (Chian, 2023; Eveleigh et al., 2013; Hantke et al., 2018; Kongeseri & Coley, 2019; Minge et al., 2014; N. R. Prestopnik & Tang, 2015; Thiel & Lehner, 2015).

Rarity in games refers to the scarcity of items, which creates a sense of achievement when obtained. This element seems to provide intrinsic and psychological motivation and encourages others to join, but it requires an investment of resources (Clarke et al., 2017). Although driven by challenges similar to rewards, an excess of rarity may dampen intrinsic motivation (Dargan & Evequoz, 2015).

Competition or cooperation among users is linked to external motivation, as it can demonstrate success and encourage others to join. However, it requires resources to play (Dargan & Evequoz, 2015; Foxman & Forelle, 2014; Hassan & Hamari, 2020; Iacovides et al., 2013; Palacin-Silva et al., 2018; Resek et al., 2024; Thiel & Lehner, 2015; Wilis & Parningotan Manik, 2022). Poor competition or cooperation mechanisms and skepticism about them may reduce engagement (Bossavit & Parsons, 2016; Bousios et al., 2017; Eveleigh et al., 2013; Foxman & Forelle, 2014; Hassan & Hamari, 2020; Palacin-Silva et al., 2018; Thiel et al., 2016; Wilis & Parningotan Manik, 2022).

Narratives, themes, plots, or story provide context and emotion, guiding user actions, and connecting with personal values and psychological engagement (Clarke et al., 2017; Eveleigh et al., 2013; Gabriel & Schmölzer, 2022; Gastil & Broghammer, 2021; Kongeseri & Coley, 2019; Padilla-Zea et al., 2022; N. R. Prestopnik & Crowston, 2011; N. R. Prestopnik & Tang, 2015; Ronzhyn et al., 2020; Tennent et al., 2016; Vicens et al., 2018). They seem to give personalized experiences and clear goals for citizens. However, sociocultural factors and skepticism in narratives can deter engagement (Foxman & Forelle, 2014; Kongeseri & Coley, 2019; Padilla-Zea et al., 2022; Quecke & Mariani, 2021).

Feedback helps to assess user actions and can motivate them by aligning with personal values (Avolicino et al., 2022; Bhéreur-Lagounaris, 2016; De Francisco et al., 2024; Gastil & Broghammer, 2021; Peischl et al., 2014). Feedback seems to provide autonomy and control to citizens. However, limited support, skepticism, and poor mechanisms can reduce engagement (Palacin-Silva et al., 2018; Thiel & Lehner, 2015).

Discovery motivates users to explore new aspects of a game. It seems to be driven by intrinsic motivation and psychological engagement, but it needs resources to interact (Pflanzl et al., 2017). Discovery provides personalized experience and autonomy or control to interact. However, skepticism and poor mechanisms seem to lower participation (Foxman & Forelle, 2014).

Social interactions engage users with each other beyond cooperation or competition. It seems to be driven by intrinsic motivation and aligns more with personal values to communicate, foster psychological engagement, and encourage participation, however, it requires an investment of resources (Bhéreur-Lagounaris, 2016; Iacovides et al., 2013; Palacin-Silva et al., 2018). Social interaction gives a sense of community and personalized experience. However, privacy concerns, socio-cultural issues, and poor interaction mechanisms seem to deter engagement (Palacin-Silva et al., 2018).

During our analysis, we noticed the ambiguities of the game elements, such as one element can target different kinds of motivations. To clarify these ambiguities, we examine their similarities, subsets, and broader specifics. For instance, 'Competition/Cooperation' relates to external and introjected motivation but can also be intrinsic. For example, competing or cooperating for rewards without comparing to others tends toward external motivation, while competing or cooperating to seek recognition tends toward introjected motivation. However, competing or cooperating purely for enjoyment falls under 'Challenges/Difficulties' or 'Social Interaction' and is intrinsic. We specify the motivational context for each element to address its complexity.

4. Discussion

Various studies have explored the link between game elements and different factors by proposing classifications (Hassan & Hamari, 2020; Resek et al., 2024; Thiel & Lehner, 2015). This paper continues in the same direction by focusing on linking game elements with personal and civic motivations as well as the drivers and barriers to citizen engagement. However, the connection between these game elements can be unclear. Therefore, this study narrows its analysis to individual game elements rather than the entirety of gamification. For instance, while an economic

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

barrier might affect overall gamification, it may not impact individual game elements. The objective is to simplify understanding the relationship between motivations and influencing factors while acknowledging the need for empirical evidence.

In our findings, we notice that static elements mainly target external or introjected motivations and require time, money, or skills. This suggests that while these elements can incentivize engagement, individuals may need to invest to participate. Further delving into the engagement, a preliminary study suggested that static game elements, such as badges and leaderboards, can effectively stimulate external motivation and foster initial engagement (Steffens et al., 2017). Therefore, by leveraging static elements, it becomes possible to jumpstart initial involvement, laying the groundwork for subsequent engagement. However, overemphasizing extrinsic rewards on these static elements can hinder engagement. This argument is backed up by Thiel & Lehner's (2015) research that indicates citizens tend to find game elements monotonous over time.

On the other hand, our findings indicate that the dynamic elements are hypothetically linked to intrinsic and identified personal motivation, except for competition and cooperation, which align more closely with external and introjected motivation. The Civic Engagement Model highlights psychological engagement as a crucial factor across all dynamic elements for maintaining emotional involvement. On a similar note, Huang et al. (2024) underscores the importance of intrinsic motivation in cultivating long-term engagement. This argument emphasizes that incorporating dynamic elements into gamified systems can foster deeper motivational connections, which are crucial for supporting long-term participation, especially in situations that require sustained engagement. We also note that socio-cultural factors emerged in dynamic rather than static elements, underscoring the importance of considering the socio-cultural context when implementing these dynamic elements.

Recognizing that static and dynamic game elements target different types of motivation is important to understanding their role in fostering engagement. Static elements relate to external and introjected motivation, making them effective for jumpstarting engagement by providing an external incentive to participate. In contrast, dynamic elements are more aligned with intrinsic and identified motivation, sustaining engagement over time by fostering a deeper emotional and psychological connection. Previous studies emphasize that external motivation is useful for starting engagement, while intrinsic motivation can maintain long-term involvement (Huang et al., 2024; Steffens et al., 2017). We suggest combining these static and dynamic game elements to encourage initial participation and sustain engagement over time.

5. Conclusions

In the realm of digital government, engaging citizens is key to generating benefits for both governments and citizens. Gamification, which uses game elements in digital government initiatives, has been explored to increase this engagement. Our literature review reveals how game elements influence citizens' motivation to participate and identifies the factors that facilitate or hinder engagement.

For our first research question on citizens' motivation, we employed the Self-Concordance Model to categorize individual motivations and utilized the Civic Engagement Model to explain civic motivations. In addressing the second question on drivers and barriers, we identified seven drivers that enhance motivation and ten barriers that impede it. For the third question on game elements, we examined the literature and linked game elements to personal and civic motivations, drivers, and barriers, as outlined in Section 3.

Our findings suggest that static game elements such as Points, Badges, and Avatars are hypothetically associated with external and introjected motivation. In contrast, dynamic elements such as Progress and Aesthetics are hypothetically related to intrinsic and identified motivation, whereas Competition/Cooperation is more aligned with external and introjected motivation. We discuss that static game elements can jump-start engagement, and dynamic game elements can sustain engagement over time. We suggest a combination of static and dynamic elements as a balanced approach to designing gamified systems, ensuring both initial participation and long-term engagement.

5.1 Limitations

We acknowledge several limitations in this research. First, the studies we reviewed were selected according to the PRISMA, which might introduce biases in study selection. The biases include the exclusion of non-English articles, reliance on Scopus and Web of Science as primary databases, and the potential oversight of some relevant studies. Second, our research specifically examines gamification in citizen engagement and may not be generalizable to other fields. Third, our discussion linking game elements to citizens' motivations and influencing factors is based on both explicit and implicit relationships in the literature, which could introduce reporting bias. Lastly, while we recognize the challenges in practical applications, such as ethical concerns, our taxonomy lacks empirical validation. Thus, the conclusions remain theoretical.

5.2 Future research

Game elements can drive meaningful engagement over time by aligning with citizens' motivations. Our proposed taxonomy facilitates the distinction between different types of game elements and offers a new avenue for studying their impacts on citizens' activities. Future research should investigate the effectiveness of these game elements in increasing citizen engagement. Additionally, researchers should incorporate studies from a wider array of sources and in multiple languages. Furthermore, empirical validation of this taxonomy is necessary, with future studies supporting it through case studies.

Acknowledgement

We thank the reviewers for their valuable guidance during the revision process and our colleagues for their valuable suggestions during the conduct of this study.

Funding or Grant

This work presented herein was funded by the Indonesia Endowment Fund for Education (LPDP) grant number: 202308221741246.

Data/Software Access Statement

Supplemental materials of the selected studies are available through https://doi.org/10.4121/0e098400-604e-4908-8155-b51ebef71c97.

Contributor Statement

Budi Satrio: Writing – original draft, Formal analysis. Fernando Kleiman: Writing – review & editing, Supervision, Conceptualization. Marijn Janssen: Writing – review & editing, Supervision.

Use of AI

During the preparation of this work, the author(s) used Rewrite/Copilot in order to improve readability. After using this tool/service, the author(s) reviewed, edited, made the content their own and validated the outcome as needed, and take(s) full responsibility for the content of the publication.

Conflict of Interest (COI)

Budi Satrio reports financial support was provided by the Indonesia Endowment Fund for Education (LPDP) grant no: 202308221741246. If there are other authors, they declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

Abstract. Public libraries hold significant potential for advancing inclusive civic engagement in government Artificial Intelligence (AI) initiatives. Drawing on interviews with 34 staff members from three public libraries across the United States—Palo Alto Public Library (PAPL) in California, Queens Public Library (QPL) in New York, and Schaumburg Township District Library (STDL) in Illinois—this study examines the AI-related programs offered by these libraries, along with the benefits, costs, and challenges associated with designing and implementing these programs. Built on the purposes of increasing awareness of patrons about AI and fostering competencies of patrons in using AI tools, public libraries offer various AI-related programs that create notable benefits for their patrons and the libraries themselves. Moreover, when designing and implementing AI-related programs, challenges such as insufficient staff expertise and limited staff engagement, as well as the lack of a unified and comprehensive strategy to promote AI-related programs to the public, must be addressed. This study also discusses that public libraries currently focus on informing citizens rather than higher levels of civic engagement, such as collaboration and empowerment. However, we argue that public libraries already provide a strong foundation for promoting civic engagement in government AI initiatives by informing citizens about the fundamentals of AI and enabling them to explore specific AI tools and applications. Future studies can build on this foundation to develop actionable strategies that public libraries can use to achieve more advanced levels of civic engagement in government AI initiatives.

Research paper, DOI: https://doi.org/10.59490/dgo.2025.1034

1. Introduction

Artificial intelligence (AI) has been increasingly adopted in various social contexts, offering a range of opportunities and risks not only to individual users but also to the broader community. For instance, several studies have recognized that AI systems can reflect and even amplify existing societal biases against marginalized populations due to the data used for the learning processes of AI systems (Bird et al., 2024; Fountain, 2022; Papakyriakopoulos & Mboya, 2023; Valle-Cruz et al., 2024). To address some of the harms and risks of AI, scholars and practitioners advocate for public engagement to incorporate diverse stakeholders' knowledge and insights across sectors and fields (European Commission, 2019). Specifically, by including the voices of a broader range of stakeholders, participatory approaches to AI initiatives can ensure transparency and accountability in implementing AI systems while fostering an environment that prioritizes inclusion and safety in the design of AI tools (Birhane et al., 2022). Nevertheless, clear strategies to engage communities in government AI initiatives and the specific identification of spaces where such engagement can take place remain lacking (Wilson, 2022).

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Previous studies address the role of public libraries in the Internet age. In this respect, public libraries have continuously evolved in the digital era to respond to the changing demands of communities, expanding their roles beyond traditional service providers or information repositories. Currently, public libraries can provide broadband and technology to bridge the digital divide, offer safe and neutral spaces for community discussions, and serve as community-center innovation hubs (Buyannemekh, Gascó-Hernandez, et al., 2024; Buyannemekh, Gil-Garcia, et al., 2024; Scott, 2011b). In the AI age, public libraries are also expected to remain active in empowering users and communities, striving to engage with community stakeholders and gather user feedback to ensure inclusive and equitable AI implementation (Hodonu-Wusu, 2024). In light of this, we argue that public libraries could also be essential in spearheading inclusive civic participation in government AI initiatives, by serving as trusted learning spaces where individuals and groups can equally access resources and knowledge, and engage in meaningful dialogues about AI and its societal implications.

However, despite public libraries being viewed as critical hubs for leveraging the benefits and mitigating the risks of AI for the communities they serve, empirical evidence and systematic knowledge on the implementation and impact of such programs remain limited. To address this gap, this study examines AI-related programs offered in public libraries, based on interviews conducted in three public libraries where AI programs have been implemented and promoted to the public. Specifically, this study focuses on two key research questions: (1) what are the purposes of providing AI-related programs in public libraries, and (2) what are the benefits, costs, and challenges of designing and implementing AI-related programs in public libraries?

2. Literature review

Given the potential impacts of AI on society, how to amplify its benefits while mitigate its risks has become an urgent question for both scholars and practitioners (Dwivedi et al., 2021; Medaglia et al., 2023; Sousa et al., 2019; Wirtz & Müller, 2019; Valle-Cruz et al, 2024; Zuiderwijk et al., 2021). Previous studies have argued that the involvement of a diverse range of stakeholders in the development of AI systems could ensure they are both beneficial and equitable (Moon, 2023). This section discusses the approach of inclusive civic engagement in AI initiatives, exploring both benefits and challenges. Furthermore, it reviews the role of public libraries in developing smart citizens, providing spaces for community innovation, and enabling citizen participation, illustrating how public libraries can serve as crucial actors in advancing an inclusive civic engagement approach.

2.1 Inclusive civic engagement in AI initiatives

The benefits of promoting an inclusive civic engagement approach have been widely acknowledged by researchers. For instance, Birhane et al. highlight several advantages of the participatory approach to AI, including the inclusion of marginalized communities, the enhancement of collective knowledge, the empowerment of communities, and the transformation of the relationships between AI designers and users (Birhane et al., 2022). Furthermore, by formalizing mechanisms and processes that evaluate the social and ethical implications of AI systems for stakeholders, AI systems can better serve public interests rather than being driven solely by corporate priorities (Gilman, 2022; Moon, 2023). As a result, a civic engagement approach to AI holds a normative justification to drive long-term benefits for the public, by democratizing AI systems as public goods that prioritize the inclusive well-being of diverse stakeholders in a sustainable manner (Maas & Inglés, 2024; Sieber et al., 2024; Taylor et al., 2024).

Aligned with the necessity of incorporating a broader range of stakeholders in an inclusive manner, several countries and international organizations have begun developing ethical governance standards to encourage civic engagement in AI initiatives across various sectors and disciplines (European Commission, 2019; Wilson, 2022). For instance, in the process of algorithmic impact assessment—a primary method for promoting algorithmic accountability—the institution employing the algorithm is expected to include multiple stakeholders in order to anticipate potential harms (Gilman, 2022). Additionally, some scholars advocate for algorithm audits, emphasizing the importance of assessing algorithms' negative impacts on stakeholders' rights in different contexts (Brown et al., 2021), as well as evaluating the accuracy, interpretability, and unintended consequences of AI systems (Engler, 2021). These efforts constitute the legitimate foundation for promoting inclusive civic engagement in AI initiatives.

However, in practice, promoting inclusive civic engagement in AI is not without challenges. One of the most noticeable challenges is symbolic participation or "window dressing," which refers to superficial involvement that lacks genuine influence or power (Gilman, 2022). As criticized by scholars, some civic engagement activities frame citizens as "customers" or "users" of AI systems, rather than active participants with meaningful input into the design, implementation, and oversight of these AI applications that impact their interests and rights (Birhane et al., 2022; Sieber et al., 2024; Taylor et al., 2024). Delgado et al. (2023) examine this wave of the "participatory turn" in AI design, finding that most projects primarily operate in a consultative mode that aims to elicit preferences and values from stakeholders instead of granting them full ownership of the projects.

Another challenge undermining genuine empowerment in AI initiatives is the prevalence of abstract strategies that recognize the importance of civic engagement without establishing concrete activities. According to Wilson's

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

analysis of 16 national strategies for AI, there is a lack of specific civic engagement initiatives and limited emphasis on engagement values (e.g., democracy, deliberation, and participation) in the AI strategies of most developed countries (Wilson, 2022). This gap highlights the need for actionable plans that go beyond rhetoric endorsement on the participatory approach to AI. Without legal and institutional frameworks that communicate actual stakeholder influence in the formation of AI systems, civic engagement can become a mere formality and fail to address the power imbalance between AI developers and other stakeholders (Massaro et al., 2022).

In light of these challenges—ranging from symbolic participation that fails to grant genuine influence, to the lack of concrete institutional and legal frameworks for engagement—it becomes essential to identify specific entities and mechanisms capable of supporting truly inclusive civic involvement in government AI initiatives. As longstanding community institutions, this study argues that public libraries are uniquely positioned to address some of these shortcomings. Specifically, public libraries offer accessible spaces and resources to foster community participation in an inclusive manner, allowing the involvement of participants from marginalized groups. Moreover, due to their historical legacy, public libraries generally have a high level of trust from the public and multiple stakeholders, positioning them as credible mediators capable of bridging diverse interests and fostering meaningful dialogue on AI-related issues. In the next subsection, we will review the studies that underscore how public libraries act as community hubs in empowering the communities they serve.

2.2 Public libraries as community hubs

Public libraries serve their communities not only as trusted institutions but also as community hubs that address the evolving needs of patrons (Buyannemekh et al., 2023; Buyannemekh, Gascó-Hernandez, et al., 2024; Buyannemekh, Gil-Garcia, et al., 2024; Hernández-Pérez et al., 2022; Sherman & Sanders, 1989; Yerden et al., 2021). Scholars have explored the role of public libraries in fostering community engagement, arguing that public libraries can encourage social inclusion and equity by functioning as "third places" that are inclusive and welcoming to all (Aabø & Audunson, 2012; Gasco-Hernandez et al., 2022; Scott, 2011b). Additionally, public libraries offer programs that serve as access points to information, benefiting community involvement and becoming vital resources for enhancing the civic health of their communities through conversation and action (Cocciolo, 2013; Scott, 2011a). These various pieces of evidence reflect that public libraries have the capacity to serve as transformative spaces, fostering both individual and collective empowerment within their communities.

Public libraries are also at the forefront of equipping their communities to navigate the rapidly digitalizing world, playing multiple roles. First, public libraries can foster the development of smart citizens by educating them about emerging technologies. For instance, in the context of smart city initiatives, researchers have highlighted that public libraries can act as key players in the governance of such projects (Mersand et al., 2019; Yerden et al., 2021). In addition, public libraries are uniquely positioned to enhance digital literacy among underserved groups and contribute to the advancement of inclusive and sustainable smart communities (Buyannemekh, Gil-Garcia, et al., 2024). Also, to respond to the increasing popularity of AI, studies have shown that public libraries can support STEM education and provide career training for in-demand skills to address trends in automation and AI (Barbakoff, 2021).

Second, public libraries provide spaces for community innovation through initiatives such as makerspaces and living labs. They serve not only as centers for co-creation between various stakeholders (Gasco-Hernandez et al., 2022; Hernández-Pérez et al., 2022) but also as community innovation hubs where technical infrastructure is accessible to the public (Buyannemekh, Gil-Garcia, et al., 2024; Mersand et al., 2019). Lastly, public libraries occupy a unique niche in enabling citizen participation in emerging technologies, fostering engagement and empowering communities to contribute to technological advancements. For example, public libraries have recently begun offering accessible AI education to the public, contributing to the enhancement of algorithmic literacy among their patrons (Ridley & Pawlick-Potts, 2021) and democratizing AI for communities (Finley, 2019). In a similar vein, by offering programs that raise awareness and build competencies in AI, public libraries have the potential to foster an inclusive approach to civic engagement around AI (Huang, Gasco-Hernandez, et al., 2024).

It is important to note that the role of public libraries have evolved over time from offering pioneering programs to advance Internet literacy and develop accessible infrastructure (Poustie, 1999), to offering e-learning opportunities and cultivating technological fluency within the communities they serve (Abumandour, 2021; Agyekum, 2022). Building upon this cornerstone, in the AI era, public libraries have undergone a profound transformation from static repositories of books to dynamic actors, functioning as educational centers and innovation hubs where citizens can access accurate information about AI, learn its essential principles, and innovate with the assistance of AI-driven applications (Adesina & Zubairu, 2023; Garnier et al., 2024; Huang, Prasad, et al., 2024). Moreover, recognizing that AI literacy is increasingly being positioned as an important skill for individuals, public libraries are adapting to these evolving demands by offering targeted courses that foster AI literacy and algorithmic literacy (Garnier et al., 2024; Ridley & Pawlick-Potts, 2021).

Therefore, in line with arguments highlighting the necessity of investing in mechanisms for communities to

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

collectively identify problems and act on AI (Moon, 2023; Taylor et al., 2024; Wilson, 2022; Young et al., 2024), we argue that public libraries are important yet often overlooked contributors to advancing this agenda. As suggested by scholars, the approach of community-based engagement in AI does not necessarily conflict with the globalized functioning of commercial AI systems (Young et al., 2024). Instead, by recognizing the importance of redistributing power toward affected communities, AI systems can serve the broader public in a more inclusive and equitable manner. That is, public libraries can be a catalyst in the process of fulfilling this goal of meaningful civic engagement in government AI initiatives.

3. Research design

To address the research questions, this study adopts a comparative case study approach. This approach enables the analysis and comparison of contextual differences and similarities across cases, thereby uncovering common patterns and unique practices related to AI initiatives in different public libraries. This section outlines the data collection process and provides background information on the selected public libraries. For the comparative, three public libraries—Palo Alto Public Library (PAPL) in California, Queens Public Library (QPL) in New York, and Schaumburg Township District Library (STDL) in Illinois—were selected as cases based on four criteria: (1) previous and current offerings of AI-related programs, (2) geographical diversity, (3) demographic diversity, and (4) research access. By examining multiple cases situated in areas with diverse citizen attributes, this study aims to provide novel nuances into the emerging practices in public libraries while identifying patterns and themes across cases. It is important to note that these three public libraries do not only offer AI-related events as one-off occurrences; rather, all three cases have continually provided AI-related programs with different goals. As a result, we argue that these public libraries invest sustained efforts in AI-related programs and consider them valuable sources for gaining insights into our research questions.

3.1 The data collection process

Owe collected data from two different sources: official documentation and in-depth interviews. First, we began by mapping the profiles of AI programs in the three selected libraries by scanning and reviewing the official websites of each library to gather information on AI-related events and documents. Additionally, a broader online search using search engines was conducted to find content from public reports and news articles, providing more background information on these cases and helping us identify potential interviewees for the next stage of the study.

Second, to gain a deeper understanding of the three cases presented in this paper, the research team conducted a total of 34 in-depth interviews with current and former staff members from each library between September and November 2024. Specifically, 8 in-person interviews were conducted for PACL, 15 online interviews were conducted for QPL, and 11 in-person interviews were conducted for STDL. Interviewees were involved in the design, implementation, or management of AI-related programs and included librarians, IT staff, library program coordinators, executive leaders within library branches (e.g., branch directors), and library services managers responsible for digital and innovative programs.

Each interview lasted between one and two hours, covering discussions on the purpose of AI-related programs, the benefits, costs, and challenges of offering these programs, and the potential strategies and considerations regarding civic engagement in AI initiatives. As part of the process, informed consent was obtained from all interviewees, with researchers explaining the study's purpose, participants' rights, and the measures taken to ensure confidentiality. The recordings of the interviews were transcribed and coded by one of the authors in this paper to ensure consistency.

For the first research question, which focuses on the purpose of offering AI-related programs in public libraries, this study employed a deductive coding approach based on categories developed in prior studies and reports (Huang, Gasco-Hernandez, et al., 2024; Huang, Prasad, et al., 2024). This strategy enables us to achieve more consistent findings, as it is built upon prior studies that mapped a broad range of cases from various public libraries across the United States. Specifically, following prior studies (Huang, Gasco-Hernandez, et al., 2024; Huang, Prasad, et al., 2024), this research identified two primary purposes for public libraries to implement their AI-related programs: raising awareness and building competencies among their patrons. The former includes activities such as conversations on AI and lectures introducing AI; the latter comprises hands-on workshops and makerspaces where patrons can learn about the practical applications of AI. Rooted in these two purposes, this study delved into examining these AI programs from the perspectives of library staff. Regarding the second research question, which examines the benefits, costs, and challenges of offering these AI-related programs, we adopted an inductive coding approach to identify emerging themes and insights directly from the interview data.

3.2 The background of interviewed libraries

Palo Alto Public Library (PACL)

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Palo Alto City, where PACL primarily serves, forms a hub of innovation with about 68,572 residents, predominantly White (48.5%) and Asian (35.4%), alongside smaller Hispanic, Black, and multi-racial populations. The city is characterized by a highly educated and relatively affluent community, with nearly 75% of the population holding a bachelor's degree or higher and a median household income of $194,782. Since 2017, Palo Alto City Library (PACL) has launched multiple AI-focused initiatives, beginning with the Robo Dojo Program, which explored robotics and coding, including speech recognition, natural language processing, and facial recognition. In 2023, PACL introduced AI at PACL, a series of workshops, lectures, and community conversations covering AI's impact in higher education, creative storytelling applications, and digital literacy for seniors.

Queens Public Library (QPL)

The Queens Borough, where QPL primarily operates, is characterized by a dense and highly diverse population. The borough has a population of approximately 2.4 million people, with a racial and ethnic composition that includes roughly 28% Hispanic or Latino residents, 27% Asian, 25% White, and 17% Black or African American individuals. The median household income is around $82,000, yet about 13% of the population lives below the poverty line, highlighting significant economic disparities within the community. Educationally, approximately 35% of residents aged 25 and older have attained a bachelor's degree or higher. Since 2020, QPL has launched three AI-related programs to provide educational and accessible information to the diverse populations of Queens borough. The first program, "We Are AI," introduces basic AI concepts and examines social and ethical dimensions. Additionally, workshops on generative AI tools—such as ChatGPT and Google Gemini—support patrons' job searches, resume writing, and productivity enhancement. For younger audiences, QPL also provides robotics programs integrate with the library's STEM curricula, fostering early interest in AI-related technologies.

Schaumburg Township District Library (STDL)

Schaumburg Township in Cook County, which STDL predominantly caters to, has evolved from a farming community into a highly diversified urban center over the past four decades. It is home to 134,809 residents, with a demographic composition of 56.38% White, 23.57% Asian, 14.88% Hispanic or Latino, and 4.53% African American. The median household income is $91,534, and only 8.7% live below the poverty line, while nearly half (46.9%) hold a bachelor's degree or higher, reflecting a solidly middle-class community with a sound economy and strong access to quality education. STDL offers several AI programs designed as educational courses to equip patrons with essential 21st-century skills. These include an introductory AI lecture, "Conversation with AI," which demonstrates generative AI tools interactively, and a recurring workshop, "ChatGPT & AI," which explores how ChatGPT works, its practical applications, and broader AI-related issues.

4. Lessons about purposes, benefits, costs, and challenges

As preliminary results, this section summarizes the main insights based on the interview data. Due to space constraints in the manuscript, we primarily integrate the results of common themes and unique perspectives emerging from the interviews without including direct quotations. Each of the two research questions is addressed in one of the following subsections, respectively.

4.1 Purposes of offering AI-related programs in public libraries

The purposes of offering AI programs vary, with two primary themes emerging from the interviews: (1) increasing awareness about AI, (2) building competencies on using AI tools. Echoing the literature mentioned above, it shows that public libraries have gradually evolved from static repositories of books into more active educational actors in response to trending AI technologies in society.

Increasing awareness of patrons about AI

As an institution whose primary role is a facilitator of information dissemination, public libraries have long served as trusted community hubs for information and learning, and their role in increasing patrons' awareness of AI is a natural extension of that mission. Staff members at various libraries emphasize the importance of keeping patrons informed about emerging AI technologies, enhancing community members' awareness and understanding of AI. For instance, staff members at PACL and STDL emphasize that these libraries design and offer AI-related programs with the goal of equipping patrons with balanced, accurate, and forward-thinking information and awareness about AI technologies. Both PACL and STDL have hosted lectures discussing how AI impacts individuals and exploring safe ways to leverage its benefits.

Similarly, with AI-related programs featuring introductory sections discussing the ethical risks and harms of automated systems conducted by local governments, staff members at QPL designed their AI programs to enable community members to critically evaluate the use of automated decision-making systems by government agencies. In doing so, public libraries can become not only the catalysts for raising public awareness on the implications of AI but also the forefront institutions for disseminating unbiased insights into how AI works.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Furthermore, public libraries facilitate conversations on AI to showcase emerging technologies to their patrons, creating a space for meaningful discussions on AI. Through interactive conversations about AI and other emerging technologies, such as blockchain, staff members at both QPL and PACL emphasize that these discussion-oriented programs not only enhance patrons' basic understanding of these complex topics but also open possibilities for rethinking the broader implications of these technologies. These efforts reflect that public libraries are becoming a crucial forum for potential further civic engagement in government AI initiatives.

For younger audiences growing up in an AI-driven world, public libraries also offer AI-related programs designed to spark their interest and raise their awareness of AI. For instance, robotics classes at QPL and PACL provide students with hands-on experimentation with AI and related technologies, fostering curiosity and enthusiasm about AI. As a result, public libraries establish a positive cycle of continuous learning and dialogue on AI, cultivating patrons' interest and awareness in this subject.

Building competencies of patrons on using AI tools

Public libraries are leveraging AI-related programs to help patrons build competencies in emerging AI tools. At STDL, for instance, staff members emphasize the importance of showing how individuals are already using AI every day—often without realizing it—and then introducing newer tools such as ChatGPT to expand their horizons. By focusing on both the potential benefits and the limitations of AI, this course invites participants to understand, discuss, and apply these resources in their personal and professional lives.

In addition, QPL offers AI workshops designed to enhance career development and build STEM competencies for all ages, from adults exploring generative AI platforms like Google Gemini to kids and teenagers engaging with robotics and coding. According to one QPL program coordinator, the goal is to guide patrons toward envisioning how these technologies might shape their future careers.

Compared to other two cases, PACL underscores the broader mission of ensuring equitable access to AI education and resources. A staff member notes that even in an area considered relatively affluent and educated, not every patron has the same opportunities to access educational resources about AI. Therefore, PACL aims to help bridge the digital divide and position itself as a catalyst for community learning and professional development through equipping users with practical AI skills.

4.2 Benefits, costs, and challenges of offering AI-related programs

Offering and implementing these AI-related programs at public libraries engenders various benefits, along with associated costs and challenges. This underscores the role of public libraries in continually contributing to their communities in the context of AI while navigating the complexities of resource allocation and program execution.

Benefits

Public libraries' AI-related programs offer multiple benefits, beginning with enhancing patrons' knowledge and literacy about emerging technologies. As staff members from various institutions note, these programs help the public recognize how AI seamlessly integrates into everyday life. By providing comprehensive, accessible, and accurate information about AI, public libraries empower patrons and help them make sense of the presence of AI technologies in their daily lives. In doing so, public libraries not only reduce misconceptions about AI but also cultivate a sense of digital preparedness within the community.

Another key benefit lies in boosting patrons' confidence in exploring AI for personal or professional pursuits. Instructors at PACL and STDL noted that participating in these AI programs encourages patrons to envision future applications of AI while providing transformative long-term benefits, such as advancing their careers or exploring new interests. In other words, these introductory experiences could serve as catalysts for patrons' future engagement with cutting-edge innovations.

In addition to the benefits for patrons, public libraries themselves can also reap substantial advantages from offering these AI-related programs. For instance, staff members at STDL and QPL underscore that AI programs can attract new audiences keen on AI education and strengthen public libraries' roles as trusted information centers. Moreover, as emphasized by a librarian at PACL, these AI programs enhance the public libraries' reputation and recognition, fostering stronger connections with their communities.

Costs

Offering AI-related programs in public libraries generally entails costs, primarily related to staff time, speaking fees, and the infrastructure required for these programs. At STDL, staff members must allocate specific time slots to ensure the continuity of generative AI programs. Furthermore, as public libraries often rely on external experts to host courses or programs, speaking fees for these experts may represent a significant expense. Lastly, some

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

interviewees highlighted costs associated with infrastructure updates. For instance, modest hardware upgrades—such as updating a graphics card—may be necessary to support advanced AI tools available in public library makerspaces.

Nevertheless, compared to the benefits associated with offering AI programs, public libraries do not appear to need to spend an exorbitant amount on providing these events and services. For instance, senior service librarians at PACL highlight that volunteers or guest speakers can significantly reduce expenses, enabling events to run at little to no cost. Moreover, while libraries such as QPL and PACL have acquired subscriptions for generative AI tools and made partial updates to their technological infrastructure, these costs are generally perceived as reasonable investments and do not impose significant financial strain on the operations of public libraries.

Challenges

The challenges of offering AI programs are not absent. Since AI programs are just one of many tasks that library staff must manage, developing and maintaining staff expertise in AI-related topics is an urgent challenge for public libraries. For instance, as emphasized by program managers at both QPL and STDL, public libraries face a fundamental challenge in cultivating and retaining staff members with domain knowledge not only to teach AI-related courses but also to design AI-related programs. Without well-trained replacements to sustain these efforts, an AI program may risk collapsing.

Another shared challenge in the three public libraries is how to genuinely encourage more staff to become involved in AI programs and training. If librarians and staff harbor personal misunderstandings or fears about rapidly evolving AI technologies, such as concerns over generative AI tools, the implementation of AI-related programs might be stymied, hindering their ability to effectively educate and engage patrons on these topics. Consequently, nurturing staff motivation and confidence—alongside ensuring adequate training opportunities—is vital.

Last but not least, our observations reveal that none of the three public libraries have developed a comprehensive strategy for designing and promoting AI-related programs to the public. For example, while QPL serves an extremely diverse and expansive area with more than 60 branches and centers, it still lacks a unified strategy to coordinate these efforts. A comprehensive strategy plan for AI-related programs could create greater synergy within a public library system through resource and information sharing. Moreover, by avoiding the siloed style of program development, public libraries can offer a wider range of diverse and complementary programs to better serve their communities.

5. Discussion and conclusion

Based on interviews with 34 staff members from three public libraries in the United States, this study examines the AI-related programs offered by these libraries and how they could help enhance inclusive civic engagement in government AI initiatives. The findings reveal that public libraries focus on two key objectives when designing and implementing AI-related programs: increasing awareness about AI and building competencies on using AI tools. Additionally, with reasonable costs, these programs yield substantial benefits for both patrons and the libraries themselves. However, challenges persist in relation to staff, particularly insufficient staff expertise, limited staff engagement, and the lack of a comprehensive strategy to promote AI-related programs. This echoes previous studies on AI in public libraries (Barbakoff, 2021; Hodonu-Wusu, 2024; Huang, Gasco-Hernandez, et al., 2024; Ridley & Pawlick-Potts, 2021), demonstrating that public libraries can supplement AI education within their communities while highlighting the need for greater investment in specific areas, such as staff development and librarian expertise on AI.

Regarding the role of public libraries in fostering civic engagement in government AI initiatives, our results show that public libraries are currently focused on the initial stages of civic engagement. Based on different degrees of citizen participation proposed by prior studies (Delgado et al., 2023; Gilman, 2022; International Association for Public Participation, 2025; Sieber et al., 2024), public libraries currently offer their AI-related programs to provide balanced and objective information as well as to collect feedback and have conversations about AI. At the present time, we did not observe higher levels of civic engagement in AI, such as collaboration and empowerment, occurring in the public libraries we interviewed. Nevertheless, these observations should not be interpreted as an indication that public libraries do not play a crucial role in civic engagement in AI.

In our opinion, while public libraries have not explicitly enabled inclusive civic engagement in government AI initiatives, they have acknowledged the importance of this agenda and seem willingness to experiment with and launch such programs in the near future. As suggested by the well-known ladder of citizen participation (Arnstein, 2019), civic engagement can be understood as a continuum encompassing different levels of citizen involvement. In this study, public libraries have demonstrated their roles to raise patrons' awareness about AI and gradually build patrons' competencies in using AI. By doing so, it can be reasonably argued that public libraries can lay a solid foundation for higher levels of civic engagement by informing citizens and familiarizing them with the basics of AI.

Civic engagement in AI is a challenging and long-term effort, as emphasized by a variety of studies conducted in different fields (Birhane et al., 2022; Delgado et al., 2023; Taylor et al., 2024; Young et al., 2024), but we argue that public libraries have the potential to advance this challenging agenda by adopting more comprehensive strategies.

For instance, public libraries can explicitly adopt the goals of inclusive civic engagement and digital literacy into their strategic plans, providing clearer guidelines for staff on program design and community outreach. Moreover, since it is crucial to allocate sufficient resources—such as budget and personnel—to effectively implement and scale these AI-related programs, public libraries should consider seeking additional funding and allocating strategic resources to support these initiatives. Last, but not least, enhancing outreach to other community-based organizations, such as school districts, churches, local nonprofits, or government agencies, could contribute significantly to improving the inclusiveness of the agenda for AI, ensuring that diverse community members are engaged in the conversation.

This study contributes to understanding AI-related programs in public libraries and the roles public libraries may play in fostering civic engagement in government AI initiatives. More research on this topic is essential, as public libraries can be key actors in inclusively engaging more citizens and communities in a society where AI increasingly influences various aspects of individuals' lives and governance. Scholars and practitioners can further investigate how to build an actionable framework that public libraries can leverage to achieve a higher level of civic engagement, as well as the drawbacks and opportunities public libraries can address in a participatory approach to AI in their communities. A systematic understanding of the role of public libraries in civic engagement for AI initiatives can not only enable public libraries to achieve their goals and visions but also ensure that AI generates inclusive benefits for the general public.

Abstract. This paper aims to examine the phenomenon of e-participation at the local level. This study addresses the following research question: What is currently known about the transition from participation to e-participation at the local level? This paper employs a systematic literature review to understand the current state of art about e-participation at the local level by identifying and categorizing the relevant structures, assessing the prevailing barriers, recognizing the challenges, and analyzing the potential benefits of e-participation at the local level. The purpose of this research is to provide insight into the existing knowledge base on the transition from traditional forms of participation to e-participation at the local level. The findings indicate that while e-participation presents an opportunity to improve democratic engagement and inclusivity, it also faces substantial challenges, including digital devices, institutional resistance, and the necessity for solid technological infrastructure. These findings have implications for both practice and academic discourse. From a practical perspective, the findings suggest that local governments need to invest in technology and digital literacy programs to ensure effective e-participation. From an academic viewpoint, the study contributes to the existing literature by providing a comprehensive understanding of the dynamics of e-participation and its implications for local governance.

1. Introduction

The idea for this paper starts with the classical article written by Sherry Arnstein (Arnstein, 2002), a valuable contribution to the literature about participation in the public sphere that investigates the changes from participation to e-participation at the local level. In the last century, democracy has altered most countries' reality (Bobbio, 1992). With this, public participation became a vital tool to understand what citizens want from a representative government (Pateman, 1992). Still, without a legally binding or mandatory observance of government decisions, some contributions aren't considered in the decision-making process and do not translate into concrete actions (Dagnino, 2004). Local instances sometimes don't have the possibilities and capabilities to focus on public policies at different levels of government (da Fonseca, 2019). All of these are influenced by the technological changes of the last century (Castells, 2005), and the participation process has also changed. Initially, the participation process was sometimes in-person and sometimes online. This changed with the COVID-19 pandemic because the participation process that was in person needs to change to digital (Criado et al., 2020).

Focusing on participation practices (Bourdieu, 2011), this paper aims to understand the current state of art about e-participation at the local level. To this end, a literature review was conducted to identify the categories, structures, barriers, challenges, and benefits of e-participation at the local level. The paper wants to answer the following question: What do we know about the transition from participation to e-participation at the local level?

This study is based on the assumption that cities have choices (Savitch & Kantor, 2004) and that localism has a particular potential to build movements in local politics in practice (Clarke & Cochrane, 2013). For years, the

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

mostly interesting practices of participation started and became strong at the local level or in the municipalities, an example of participatory budgeting (Dagnino, 2002; Fedozzi & Martins, 2015; Lüchmann, 2014). Participation is a part of the democratic system and a way to involve citizens in the public sphere. Understanding where we are situated in participation literature is fundamental to attempting to impact society. The following theory and literature review aim to advance our comprehension of the elements that potentialized public participation.

This contributes to the existing literature and, as a consequence, to the development of new research by providing elements that contribute to an understanding of the actual stages of the transition from participation to e-participation. The remainder of this paper is structured as follows: section 2 presents a brief theoretical foundation, section 3 describes the methodological procedures, section 4 presents the participation categories identified in the studies, section 5 discusses the main findings from the research analyzed and, finally, section 6 presents the final remarks.

2. Theoretical Background

2.1 Democracy

To discuss participation, it is first necessary to define democracy. Given the infinite number of democratic systems in existence, it is evident that not all of them provide adequate space for effective citizen participation. In this paper, we will make a distinction between two forms of democracy: on the one hand, we will examine dominant forms of democracy, and on the other, we will consider alternative, counter-hegemonic systems. (Miguel; Vitullo, 2021a).

For Ellen Wood, the hegemonic conception - also known as liberal or bourgeois – defends a merely representative democratic system, where the people's form of participation is only through periodic voting to choose representatives who will fulfil their mandate for a certain period, without, in most cases, existing direct dialogue with the voting people (Wood, 2011). On the other hand, counter-hegemonic democracy is based on the conception of the democratic system adopted in ancient Greece, where there was no political state structure distinct from the people, considering citizen participation as a central fact (Wood, 2011).

According to Wood (2011), the concept of democracy has historically been inserted into the field of social tensions as political strategies of the dominant classes aiming to perpetuate a model of representative, hegemonic democracy adopted by most so-called democratic countries. From this point of view, democracy is much more a method of choosing representatives than a system of representing the people's will.

It is important to understand that the dominant currents of democracies have different origins and, therefore, founding conceptions that lead to divergent democratic practices (Bourdieu, 2007). According to Wood (2011), one of the central criteria of democracy is the balance of power between rich and poor, and what would be intrinsic is the condition of being a citizen, not each one’s economic condition. In a capitalist democracy, the distinction between civic status and class position functions bidirectionally: socioeconomic status does not dictate the right to citizenship, embodying the democratic aspect of capitalist democracy. Still, the capitalist's ability to appropriate workers' surplus labour remains unaffected by privileged legal or civil status. Consequently, civil equality does not directly influence or substantially alter class inequality, thereby constraining democracy within capitalism. Class relations between capital and labour persist despite legal equality and universal suffrage (Boron, 2001; Wood, 2011).

Therefore, although there is civil equality where everyone is seen as a rightful citizen, regardless of socioeconomic position, this is superimposed in the capitalist context. Democracy becomes limited since civil equality is not capable of modifying the logic of exploitation and class inequality. The concept of democracy becomes accepted by the elite classes to the extent that it is useful to them and allows them to maintain power in their hands. This can be analyzed according to the “generalized defamation of democracy by the dominant classes” (Wood, 2011, p.194), allowing it to be subjected to a transformation that makes it “possible for its enemies to yesterday to hug her” (Wood, 2011). This “transformation” pointed out by Wood can be understood in part as the minimization of mass participation in political life.

In this original sense, democracy was understood to refer to government by the demos, or the "people," with the additional double meaning of civil status and social category. In "representative democracy," the principle of government by the people remained the primary criterion for defining democracy, even though government was filtered through representation controlled by the oligarchy, and the people were stripped of their social content. In the following century, the concept of democracy would become increasingly divorced from its ancient and literal meaning (Wood, 2011, p. 194).

Participation theories are based on the concept of democracy within our system. They aim to broaden the possibilities of generating active citizenship and, consequently, change the system's structures (Pateman, 1992a). Within the prevailing paradigm, wherein representation is the dominant model, participation is either absent or

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

perceived as transparency and social control (Lavalle; Vera, 2011). In the counter-hegemonic current, participation is the primary focus, with social control and transparency serving as conditions that facilitate participation (Miguel; Vitullo, 2021b).

2.2 Theories and the concept of participation

Participation, in its etymological Latin derivation, is derived from the term "participatio", meaning to take part in the action. The term's etymological origin elucidates the necessity of access to act and collaborate in decision-making. Many authors have examined this issue, offering perspectives on the significance of participation, underscoring its human necessity, the pedagogical and constructive role of participation, and proposing strategies for the development of greater participation (Arnstein, 2002; Barber, 2003; Bobbio, 1992; Bordenave, 1983; Pateman, 1992a).

Bordenave (1983, p. 10) writes that participation is a fundamental human need and, thus, a human right. The author maintains that participation is justified in and of itself, independent of its outcomes: "Participation facilitates the growth of the population's critical awareness, strengthens their power of demand, and prepares them to acquire more power in society" (Bordenave, 1983, p. 12), a process that leads to the people's appropriation of development. Furthermore, the author posits that participation can be learned, like Pateman (1992). Participation does not have a ready-made formula; rather, it can be provoked and organized in a manner that does not result in manipulation. Participation is facilitated by organization and creating spaces and networks that facilitate communication, always respecting individual differences in how people participate (Arnstein, 2002; Barber, 2003). The author posits that participation can be understood as having two distinct bases. The first is an effective base, which is a sense of enjoyment derived from engaging with others in collective endeavours. The second is an instrumental base, which can be understood as a perception of efficiency and effectiveness gained from working with others rather than alone (Bordenave, 1983).

In a similar vein, the author posits that citizens can engage in "micro-participation" and "macro-participation" (Bordenave, 1983, p. 21). The former is defined as natural participation, which encompasses involvement in family, school, community, and association activities. The latter is characterized by a conscious intention to utilize participation as a means of influencing social, economic, and political struggles within one's immediate context. Consequently, social participation (or participation at a macro level) is defined as the process by which different social groups participate in the production, management, and enjoyment of the goods of a historically determined society. Nevertheless, both forms of participation are mutually reinforcing, as the former, in addition to achieving immediate objectives, can also serve as an opportunity for the learning process and the primary pathway to the full exercise of citizenship (Bordenave, 1983, p. 57).

Furthermore, as a theoretical contribution, Bordenave characterizes participation in levels based on two key questions: "How much control do the members have over decisions? How relevant are the decisions that they can participate in?" (1983, p. 30). The levels of participation range from the lowest, information, to the highest, self-management. At the lower end of the spectrum, the decision-making power of the leaders is greatest, as they are the sole decision-makers, and citizens are merely informed. At the next level, optional consultation, the administration may, if it chooses, consult the population on a given subject. This precedes compulsory consultation, in which the government must consult the public on certain issues. The next level, drafting/recommending, is where the public can propose and recommend actions that the administration can accept or reject. Co-management assumes a slightly greater proportion, as administration is shared through shared or collegiate decision-making. Delegation, on the other hand, is when participation is delegated to citizens in certain areas in which they have the autonomy to decide. Finally, the final level is self-management, in which the distinction between administration and citizenship is diminished, and the groups themselves determine their objectives, choose the means of execution, and establish controls without the interference of external authorities (Bordenave, 1983, p. 30–33).

In her seminal work, Participation and Democratic Theory (1992), Carole Pateman delineates three distinct forms of participation: Pseudo-participation occurs when there is only consultation on a matter by the authorities, and participation is limited to endorsing a decision that has already been made. Partial participation is a situation in which many take part in the process, but only one party decides. On the other hand, full participation is a situation in which each group of individuals has equal influence on the final decision (Pateman, 1992a). Two points in Pateman's theory of participation are noteworthy. The first emphasizes the educational function of participation, while the second underscores the pivotal role of participation in industrial settings for workers. In these two points, the author is referring to a theory of participatory democracy (Pateman, 1992a).

Sherry Arnstein observes a paucity of in-depth analyses of the content of the controversial slogans currently used, such as "citizen participation" or "maximum possible participation," even in academic circles. The author's solution to the problem primarily imposes the integration of empowerment within the participatory framework of the aforementioned groups, which she identifies as the group of the have-nots: blacks, Mexican immigrants, Puerto Ricans, Indians, Eskimos, and poor whites. These groups' conception of participation as a means of redistributing

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

power is a central aspect of her argument (Arnstein, 2002).

The term participation is often used as a synonym for citizen power. In essence, participation is the redistribution of political and economic power, allowing those currently excluded to become actively included in future decision-making processes. It is the strategy through which those without a voice are integrated into the decision-making process. In essence, participation is how those without a voice can promote significant social reforms that allow them to share in the benefits of the surrounding society (Arnstein, 2002).

Among Brazilian authors, the contributions of Dallari, who made significant efforts to advance this discussion during the Brazilian military dictatorship, are worth noting. In his 1984 publication, "What is Political Participation?" the jurist posits that decision-making is a necessity for society and that a political system is only democratic when decisions are taken freely and the will of the majority is respected. According to the jurist, if "everyone recognizes this need and positively assumes their responsibility," conflicts will be overcome more fairly and in a manner that aligns with common needs (Dallari, 1984, p. 25). The theoretical framework is thus based on the acquisition of this right by the population, beginning with the Universal Declaration of Human Rights, which states in Article 21 that "all human beings have the right to take part in the government of their country directly or through freely chosen representatives" (ONU, 1948). The construction proceeds from the law to the citizen's influence on the social environments in which he lives, as the author asserts that every individual exerts social influence.

Dallari's work is most closely aligned with that of the authors in his assertion that "for the people to choose authentic representatives, there must, first of all, be full freedom of information, allowing people to freely form their opinions based on as much data as possible" (1984, p. 41). In this sense, he posits that participation leads to awareness and organization, and he distinguishes between formal and real participation. Formal participation, which he defines as "the practice of formality that only affects secondary aspects of the political process", does not influence fundamental political decisions. In contrast, real participation "is that which influences fundamental political decisions in some way" (Dallari, 1984, p. 92).

Notably, none of the authors view participation as a substitute for representation, particularly in large-scale democracies. All the authors assert that participation is a foundational process for democracy and serves to complement representation (Arnstein, 2002; Bordenave, 1983; Dallari, 1984; Pateman, 1992a). For this to be viable, it is essential to embrace a contemporary conception of democracy, wherein participation is situated at the core of the decision-making process.

The advent of technology has also impacted participatory practices, with many shifting from a face-to-face format to an online one. Consequently, the literature is beginning to discuss e-participation, which is often used interchangeably with digital participation. This concept will be further examined in the subsequent section of this paper.

2.3 E-participation

E-participation emerged in the mid-1990s because of government informatization. Also called electronic participation or, more recently, digital participation, refers to the use of Information and Communication Technologies (ICT) to engage citizens in government decision-making and public policymaking (Quintero-Angulo; Sánchez-Torres; Cardona-Román, 2020). The concept of "eParticipation involves the extension and transformation of participation in societal democratic and consultative processes, mediated by information and communication technologies (ICTs)" (Sanford; Rose, 2007, p. 1). It encompasses not only democratic participation but also citizen involvement in e-government service delivery (Simonofski et al., 2021). It is a complex phenomenon involving various activities, including online expression and interaction (Tai; Porumbescu; Shon, 2020). It is not a separate form of participation but rather a complement to traditional modes of participation (Kubicek, 2010).

E-participation is considered a citizenship technology, increasing citizen involvement and collaboration in political processes (Banjac, 2017). It is an emerging research area focusing on using ICT to facilitate government-citizen relationships (Sanford; Rose, 2007). Despite its potential, implementing e-participation initiatives often falls short of expectations as a result of limited knowledge and policies (Mukherjee, 2019). Macintosh (2004) mentions the need for e-enabling to support the process of e-participation, as it is not enough to have the tool; you need to know how to deal with the amount of information beyond internet access. In addition to enabling, the author brings up the need for engaging as a second stage of the Levels of Participation model (Macintosh, 2004). Finally, in this model, we come to empowerment, which is characterized by citizens becoming producers of public policy and being involved in its formulation and agenda (Macintosh, 2004).

Working on the role of e-participation in expanding capacities, Macadar, Pereira, and Pinto (2019) place e-participation as a mechanism for expanding capacities since it increases the democratic and participatory involvement of individuals in society. Here, e-participation is shown as a different way of making participation in

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

democratic spaces effective, but with the same discussion of intrinsic and necessary values for participation, even more so because, as the authors point out, e-participation is not yet available to everyone, in this case, indirectly contributing to the increase in social inequalities, thus requiring the formulation of public policies to reduce the digital lacking (Macadar; Pereira; Pinto, 2019).

More recently, in an examination of how to integrate citizen deliberation in climate assemblies through governance, Boswell, Dean and Smith (2022) concluded that in public deliberation spaces, such as assemblies, the more space is opened up to stakeholders, which can help the governance process, the more difficult it is to attract wide publicity and grassroots activists to the discussion. This leads the authors to warn against being conscious of choices, as they generate trade-offs and unintended consequences for the deliberation process. The effectiveness of e-participation is contingent on its integration into existing participation processes (Kubicek, 2010).

Despite the proliferation of e-participation initiatives, their impact on broader and deeper citizen participation remains uncertain (Blanc, 2020), and some authors are trying to understand the cause of the decrease in e-participation (Pozzebon; Cunha; Coelho, 2016). The field of e-participation is dynamic, with a growing variety of tools and technologies available (Ergazakis; Metaxiotis; Tsitsanis, 2011; Tambouris; Kalampokis; Tarabanis, 2008). However, the potential of e-participation at the local level and in urban planning is not fully realized, and its low acceptance may be attributed to a lack of understanding of its context and barriers (Kubicek, 2010). Despite its potential, e-participation faces challenges, including needing a more comprehensive evaluation and identifying problem areas (Quintero-Angulo; Sánchez-Torres; Cardona-Román, 2020). This literature review aims to collaborate in this field.

3. Methodological procedures

To better understand how the scientific world has recently dealt with the issue of participation and e-participation, we decided to consult the main scientific bases using the systematic literature review methodology (Chapman, 2021; Denyer & Tranfield, 2009), investigating aspects to understand the approaches and elements of participation in studies on urban governance at the local level. The systematic review followed the following steps: elaboration of the research problem, definition of the corpus of analysis, construction and validation of the research strategy, data collection, reading the titles and abstracts, data cleaning based on exclusion criteria, complete reading of the articles and data analysis (Denyer & Tranfield, 2009).

The corpus of this research is constituted by articles on participation and e-participation, indexed in the databases Web of Science (WoS), Spell (Scientific Periodicals Electronic Library), Scopus, and Scielo (Scientific Electronic Library Online), without applying any filters regarding the year of publication. The databases were chosen considering that WoS and Scopus are world-renowned databases in different scientific fields; Spell is a reference in Brazil, especially in the fields of public and business administration, accounting, and tourism, and Scielo is a reference in studies carried out in Latin America.

The data were collected in April and May 2024, and the search strategy was determined based on the author's interest in research. The search strategy consisted of the search criteria shown in Table 1.

Table 1 – Criteria of Search

Data were collected from the databases and cleaned using the Rayyan software developed by the Qatar Computing Research Institute (QCRI) for systematic literature reviews (Ouzzani et al., 2016). All the cleaning follows the PRISMA protocol (Page et al., 2021). The software was used to read the documents' titles and abstracts and define the exclusion criteria. Documents without the words participation and e-participation in the abstract, articles dealing with participation in private spaces, which is not the focus of this study, and articles not focusing on participation and e-participation at the local level were excluded. Figure 1 shows the details of the PRISMA flowchart for the data collection and cleaning phases, describing the results of the article identification, screening, and included phases.

Figure 1 – Stages of collecting and cleaning data

Source: Elaborated by the author using Rayyan software (2024)

The literature search results in a total of 325 documents from the databases. After 68 duplicates were removed, 257 documents remained for title and abstract screening. Out of these, 179 documents were excluded as they were

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

irrelevant to the research subject, resulting in 78 documents being included in the sample for this literature review. In the search, there was no year limitation. The included documents consisted of 59 papers from scientific journals, 9 book chapters, and 10 conference papers. Access to the full text was not possible for 16 documents (3 journal papers, 5 conference papers, and 8 book chapters). Therefore, 62 full-text documents were available for the literature analysis. In the second phase, from the detailed analysis of these 62 texts, 21 were excluded for not fitting the research focus. The reasons for exclusion are shown in Table 2:

Table 2 – Reason for exclusion in the reading phase

Reason for exclusion	Reference
General Public Participation without Digital Focus	(Aravena & Silva, 2020; Esau, 2018; Lima-Silva et al., 2020; Panagiotopoulos et al., 2012).

Other discussions not related to this research	(de Moura, 1997; Goulart et al., 2016; Hernandez Bonivento, 2022; Mallan, 2018; Panagiotopoulos et al., 2011; Ruiloba Núñez, 2014)

Source: Elaborated by the author (2024).

After reading the documents, 41 documents remain for the next stage of literature review. After a detailed reading of the articles, the different types of participation were identified, and the papers were categorized for analysis. The concepts that informed the discussions are presented below.

4. Concepts of Participation applied to the Local Level

According to the objective proposal and the application of the methodology, 41 studies are relevant to this paper.

4.1 Documents description

The first article indexed in Scopus was published in 2006 in the journal RWIT Transactions on Information and Communication Technologies, with the title E-democracy and citizen's empowerment: A case study of the city of Madrid (Santos & Alonso, 2006). The authors identify the use of ICTs to improve the relationship between citizens and government, increasing participation and the quality of public services. Over the last 18 years, research on the subject has been increasing, demonstrating the growth of interest in the topic.

As for the methodological aspects of the research, qualitative approaches are predominant, as shown in Table 3, with the predominant use of case studies, demonstrating the possibility of carrying out studies using other methodologies.

Table 3 – Studies approach and methodologies

Study Approach	**Study Approach/ Method**	**Authors**
Qualitative	Case Study	(Chun & Cho, 2012; Ntaliani et al., 2017; Revyakin, 2018; Rexhepi et al., 2018; Royo et al., 2020; Santos & Alonso, 2006; Scherer & Wimmer, 2012; Silva, 2020; Sivarajah et al., 2016; Steinbach & Süß, 2018; Ntaliani; Costopoulou; Karetsos, 2017; Sivarajah Et Al., 2016; Chun; Cho, 2012; Scherer; Wimmer, 2012; Santos; Alonso, 2006).

Source: Elaborated by the author (2024).

Based on an analytical reading of the articles, the different categories of studies and the main concepts covered in the research will be presented below.

4.2 Analytical categories

After reading all the documents, an effort was made to categorize the papers, and five categories emerged from the analysis. Table 4 presents the results:

Table 4 – Papers categories

Categories of Analysis	**Number of studies**	**Authors**
Challenges and Barriers to E-Participation	8	Man; Manaf, 2024; Hovik & Giannoumis, 2022; Lee & Kim, 2012, 2018; Naranjo-Zolotov, Oliveira, Cruz-Jesus, et al., 2019; Norris & Reddick, 2013; Ntaliani et al., 2017; Zolotov et al., 2018.
Empowerment and Citizen Engagement	6	Åström, 2020; Chun & Cho, 2012; Naranjo-Zolotov, Oliveira, Casteleyn, et al., 2019; Santos & Alonso, 2006; Silva, 2020; Steinbach et al., 2020.
Impacts and Benefits of E-Participation	9	Åström & Granberg, 2008, 2008; Colombo, 2010; Graziano, 2017; Legard et al., 2019; Legard & Hovik, 2022; Reddick & Norris, 2013; Revyakin, 2018; Rexhepi et al., 2018;
Technologies and Tools for E-Participation	7	Dias Cordeiro & Cacho Alessandro, 2018; Feeney & Welch, 2012; Kim & Lee, 2012; Li & Kostka, 2022; Mærøe et al., 2021; Sivarajah et al., 2016; Tejedo-Romero et al., 2022;
Theoretical Models and Practices of E-Participation	11	Costopoulou et al., 2017, 2021; Cropf & Benton, 2019; Pilehvar, 2021; Porwol et al., 2014a, 2014b, 2016; Royo et al., 2020; Scherer & Wimmer, 2012; Smith, 2007; Steinbach & Süß, 2018.

Source: Elaborated by the author using NVIVO (2024).

Eleven studies were classified as Theoretical Models and Practices of E-Participation; this category includes studies that develop and analyze theoretical frameworks and practical approaches for implementing e-participation. These papers provide models and guidelines for best practices, which inform policymakers and practitioners about strategies for promoting citizen engagement through digital means.

Nine studies address the Impacts and Benefits of E-participation. These impacts can include increased

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

transparency, improved accountability, greater citizen empowerment, and improved public trust in government. The papers explore both the direct and indirect benefits of e-participation. They show how digital tools can transform the relationship between citizens and their governments.

Eight studies focus on Challenges and Barriers, alerting us to the various obstacles that hinder the effective implementation and adoption of e-participation initiatives. These obstacles can be technical, social, and organizational. Studies in this category aim to identify these barriers and propose solutions to overcome them, ensuring broader and more effective citizen engagement.

Seven studies are about Technologies and Tools for E-participation. In this category, the researchers focus on developing, analyzing, and implementing technological tools and platforms designed to facilitate e-participation. These tools range from deliberation models and ontologies to various e-government applications and open data platforms. The first concern of these studies is to understand how technology can be used to improve citizen engagement, streamline decision-making processes, and increase governance efficiency.

Six studies can be categorized as Empowerment and Citizen Engagement. These papers explore how e-participation tools and platforms can empower citizens and improve their engagement in public affairs. These studies often focus on the social and psychological aspects of participation, including how digital tools can make citizens feel more involved and influential in governmental decision-making processes. With these five categories, it is possible to understand the state of research on e-participation.

5. Discussion about participation and e-participation

5.1 Structure of E-participation: insights from recent studies

E-participation is defined as using digital technologies and online platforms to engage citizens in the governance process. This involvement can take numerous forms, extending from simple information dissemination to more complex deliberation and decision-making processes. A review of the literature reveals that the structure of e-participation is composed of several elements.

The first key component is the technological infrastructure, an element decisive to the success of e-participation. This includes developing and deploying various digital platforms such as websites, mobile applications, and social media channels that facilitate citizen engagement. These platforms must be user-friendly, accessible, and secure to ensure broad participation (Porwol; Ojo; Breslin, 2014b; Sivarajah et al., 2016).

The second component to be considered is citizen engagement mechanisms because e-participation platforms could be distant and quickly lose interest. These mechanisms must provide citizens with multiple options to express their opinions, contribute to discussions, and make decisions on public matters. It can include online forums, surveys, participatory budgeting and deliberative spaces, and polling (Royo; Pina; Garcia-Rayado, 2020; Zolotov; Oliveira; Casteleyn, 2018).

The third element is institutional support because e-participation demands a will from political agents and strong support from local government. This includes resources, the establishment of supportive policies, and the training of public officials to manage and promote e-participation initiatives effectively (Reddick; Norris, 2013; Tejedo-Romero et al., 2022).

The fourth element is inclusivity and accessibility, one of the major problems today. Platforms for e-participation need to be inclusive and accessible to all segments of the population. This involves designing platforms that accommodate people with disabilities, providing content in multiple languages, and addressing the digital divide by offering public access points and digital literacy programs (Checkoway; Allison; Montoya, 2005; Ntaliani; Costopoulou; Karetsos, 2017; Rexhepi; Filiposka; Trajkovik, 2018).

The fifth component is transparency and accountability. E-participation platforms must be transparent in their operations, allowing citizens to see how their inputs are used and what impact they have on decision-making processes. This transparency helps build trust and encourages continued citizen engagement (Chun; Cho, 2012; Kim; Lee, 2012).

The last component is continuous feedback and evaluation to improve e-participation initiatives. Gathering feedback from users and conducting regular assessments help identify areas for improvement and ensure that the platforms meet citizens' evolving needs (Graziano, 2017; Legard et al., 2019).

The structure of e-participation is complex, involving technological, institutional, and social components. Effective e-participation platforms require solid technological infrastructure, diverse engagement mechanisms, strong institutional support, inclusivity, transparency, and continuous feedback. The successful integration of these

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

elements can improve citizen e-participation, improve governance processes, and cultivate a more engaged and informed public.

5.2 Barriers and difficulties of implementing participation and e-participation at the local level

Implementing participation and e-participation at the local level is a complex effort that faces numerous barriers and difficulties. These challenges can be broadly categorized into technological, social, organizational, and political barriers. Ntaliani, Costopoulou, and Karetsos (2017) discuss infrastructure and access as technological barriers because one of the most serious is the lack of adequate infrastructure. Local governments struggle with old technology, limited internet access, and insufficient digital tools. In the same way, Rexhepi, Filiposka, and Trajkovik, (2018) emphasize youth participation, bringing the problem of digital divide in society, which refers to the gap between those who have access to modern information and communication technology and those who do not, what remains a relevant issue. This divide can be based on socioeconomic status, age, geographic location, and education level, limiting the reach and inclusivity of e-participation initiatives.

The literature reveals concerns about social barriers, digital literacy, trust, and privacy. Kim and Lee (2012) demonstrated concern about trust in government and privacy and data security. One recommendation is that ensuring that personal data is protected and that platforms are transparent about how data is used is central to building trust. Regarding digital literacy, many citizens lack the necessary skills to use and engage with the participation platforms. The studies emphasize the necessity of adequate training and support, as these individuals are unable to participate fully in digital governance processes (Chun; Cho, 2012; Kim; Lee, 2012; Lee; Kim, 2012).

Regarding organizational barriers, two situations are concerned: resource constraints and the lack of expertise. In the public sector, financial and human resources often face constraints, but implementing e-participation platforms requires investment, and many local governments struggle to allocate resources to these initiatives. The same situation concerns human resources with expertise in digital technologies and public engagement. Many local government officials absence the necessary training and knowledge to manage these platforms effectively (Reddick; Norris, 2013; Tejedo-Romero et al., 2022).

The last barrier is political because, with frequency, the elected political officers often resist sharing the power with the people or the participatory institutions. The success of e-participation initiatives heavily depends on the political will of local leaders. Without a strong commitment from political leaders to prioritize and promote these initiatives, e-participation is unlikely to be effectively implemented. Traditional bureaucratic structures and processes can be inflexible, making it difficult to integrate new e-participation tools and methods (Norris; Reddick, 2013; Zheng; Schachter; Holzer, 2014).

Implementing both participation and e-participation at the municipal level presents several significant challenges. Technological limitations, such as deficiencies in infrastructure and the digital divide, impede accessibility to digital platforms. Social barriers, including digital literacy and trust issues, further diminish citizen engagement. Organizational constraints, such as insufficient resources and expertise, impede the deployment and management of electronic participation tools. Finally, political barriers, including resistance to change and a lack of political will, can impede the implementation of these initiatives.

To address these barriers, a multifactorial approach is required. Investments must be made in technology infrastructure and digital literacy programs. The establishment of trust through the implementation of transparent practices and data security measures can facilitate increased participation. In addition, local governments must ensure the allocation of sufficient resources and the provision of training to officials. It is of the utmost importance that strong political leadership and commitment be present to drive the adoption and success of e-participation initiatives.

5.3 Agents influencing the e-participation process and their power dynamics

The implementation and success of e-participation initiatives at the local level are influenced by various agents, each playing distinct roles with different degrees of power and influence. These agents include local government officials, citizens, technology providers, and civil society organizations. Understanding the dynamics between these agents is fundamental for designing effective e-participation systems.

Local government officials are central to the e-participation process. They are responsible for initiating, managing, and promoting e-participation platforms. Their commitment and support are critical for the allocation of resources and the integration of e-participation into the broader governance framework. As decision-makers, they have considerable power. Their attitudes towards e-participation can greatly influence its adoption and effectiveness. Strong political will and managerial support can drive successful e-participation initiatives, while resistance or lack of interest can block the process or make it just a formality without effectiveness (Norris & Reddick, 2013; Reddick & Norris, 2013; Tejedo-Romero et al., 2022; Zheng et al., 2014).

Citizens are the primary users of e-participation platforms. Their engagement is important for the success of these initiatives because they can contribute with opinions, feedback, and decisions through various digital tools provided by local governments. The paradox of participation is while citizens are the main beneficiaries of e-participation, their power is often limited by their access to technology, digital literacy, and the responsiveness of government officials (Åström, 2020; Kim & Lee, 2012; Mærøe et al., 2021; Rexhepi et al., 2018).

Civil Society Organizations (CSOs), including non-governmental organizations (NGOs), advocacy groups, and community organizations, often act as intermediaries between citizens and government. Sometimes, they have a place to represent part of society in participatory institutions. They can facilitate e-participation by mobilizing communities, providing digital literacy training, and advocating for citizen interests. Their power comes from their ability to organize collective action, advocate for policy changes, and provide expertise in specific areas of public interest (Boswell et al., 2022; Chun & Cho, 2012; Smith, 2007).

The power dynamics in e-participation are shaped by the interactions between these agents. Local government officials typically hold the most power in terms of decision-making and resource allocation. However, the influence of citizens and CSOs can increase through active engagement, advocacy, and the effective use of technology. Technology providers hold technical power, influencing the usability and functionality of e-participation platforms. Balancing these power dynamics is decisive for the success of e-participation. Ensuring that citizens and CSOs have meaningful opportunities to contribute and influence decisions can lead to more inclusive and democratic governance (Boswell et al., 2022; Chun & Cho, 2012; Smith, 2007).

5.4 Factors that improve e-participation at the local level

Based on the literature review, there are best practices that should be considered when developing a model for implementing an e-participation tool at the local level. These best practices are fundamental for ensuring the success and effectiveness of the e-participation initiatives (Table 5).

Table 5 – Findings

Finding	Details	References
Solid Technological Infrastructure	Ensure high-speed internet access, reliable digital platforms, and secure data management systems.	Porwol *et al*. (2014), Sivarajah *et al*. (2016)
User-Friendly Platforms	Design intuitive interfaces with clear instructions and easy navigation to lower barriers to entry.	Ntaliani *et al*. (2017), Chun & Cho (2012)
Strong Institutional Support	Secure financial backing, active promotion by public officials, and integration into governance frameworks.	Reddick & Norris (2013), Tejedo-Romero *et al*. (2022)
Citizen Education and Digital Literacy	Provide educational programs and workshops to improve digital literacy among citizens.	Kim & Lee (2012), Rexhepi *et al*. (2018)
Inclusivity Measures	Ensure platforms are accessible to all, including support for disabilities, multilingual content, and bridging the digital divide.	Silva (2020), Santos & Alonso (2006)
Transparency and Accountability	Maintain transparent operations and clear communication on how citizen input is used.	Royo *et al*. (2020), Zheng *et al*. (2014)
Continuous Feedback and Evaluation	Regularly gather user feedback and conduct evaluations to improve platforms.	Legard *et al*. (2019), Graziano (2017)
Engagement Mechanisms	Utilize various tools like online forums, surveys, and participatory budgeting to engage citizens.	Royo *et al.* (2020), Zolotov *et al*. (2018)
Partnership with Technology Providers	Collaborate with technology providers to ensure platforms meet civic needs and are technologically sound.	Porwol *et al*. (2016), Sivarajah *et al.* (2016)
Inclusive Decision-Making	Involve diverse groups of citizens to ensure broad representation in decision-making.	Kim & Lee (2012), Hovik *et al*. (2017)

Source: Elaborated by the author (2024).

The implementation of e-participation at the local level represents a significant advance in democratic engagement, providing a platform for increased citizen involvement in governance processes. This paper has examined the multiple aspects of e-participation, highlighting the critical components necessary for its successful implementation and the barriers that must be addressed.

First, a solid technological infrastructure is indispensable for the success of e-participation initiatives (Porwol et al., 2014b; Sivarajah et al., 2016). These technological investments ensure that e-participation tools are both

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

accessible and trusted, thereby fostering greater citizen engagement. User-friendly platforms are also needed. Studies by Ntaliani et al. (2017) and Chun & Cho (2012) highlight the importance of designing intuitive interfaces that are easy to navigate. The role of local government officials is decisive. Research by Reddick & Norris (2013) and Tejedo-Romero et al. (2022) emphasizes the need for strong institutional support, including financial backing and active promotion by public officials. In addition, citizen education and digital literacy are critical factors that influence the effectiveness of e-participation. The literature shows by equipping citizens with the necessary skills, these initiatives can increase engagement. In the same way, inclusivity policies are equally relevant, ensuring that e-participation platforms are accessible to all population segments.

Transparency and accountability are fundamental to building trust in e-participation initiatives. Royo et al. (2020) and Zheng et al. (2014) emphasize the need for transparent operations and clear communication about how citizen input is used. This transparency fosters trust and encourages continued citizen participation. Continuous feedback and evaluation are necessary for continuously improving e-participation platforms. Studies by Legard et al. (2019) and Graziano (2017) show that regular feedback from users and periodic evaluations help identify areas for improvement, ensuring that platforms remain responsive to citizens' needs and preferences.

Engagement mechanisms, such as online forums, surveys, and participatory budgeting tools, provide multiple avenues for citizen participation. The effectiveness of these mechanisms has been demonstrated by Royo et al. (2020) and Zolotov et al. (2018), showing that diverse tools can facilitate richer and more meaningful citizen engagement. Partnerships with technology providers are critical to ensure that e-participation platforms are technologically sound and meet the needs of citizens. The collaborative efforts highlighted by Porwol et al. (2016) and Sivarajah et al. (2016) demonstrate the value of aligning technological solutions with local governance requirements. Finally, inclusive decision-making processes, as advocated by Kim & Lee (2012) and Hovik & Hanssen (2017), ensure that diverse groups of citizens are represented in the e-participation process. This inclusivity is fundamental for creating a participatory governance model that reflects the community.

6. Final remarks

The research results suggest that the successful implementation of e-participation at the local level depends on a multifactorial approach that addresses technological, social, and institutional factors. By following the best practices and lessons learned from the literature, local governments can create effective e-participation platforms that increase democratic participation and foment a more inclusive and responsive governance system.

This approach emphasizes the importance of incorporating the experiences and knowledge of key agents to contribute to urban governance. The analysis of the papers raised questions about the perception of agents in relation to participation and whether these agents are willing to share decision-making. Understanding the role of different agents in the participatory process, the barriers, and good practices helps to better understand the e-participation scenario. Given these aspects, future studies could investigate the relationships between agents and the impact on decision-making, demonstrating the power relations between the agents involved and the structure of e-participation.

As a possible limitation of the study, it should be acknowledged that the database refinement stage did not consider studies published in languages other than English, Spanish, and Portuguese. It is suggested that, in future studies, the search should be broadened to include other international publications. With this study, we hope to see new research that describes, discusses, exemplifies, and formulate proposals for more participatory cities.

Track 13: Legal Informatics – Foundations and Applications

Track Description

Legal informatics is concerned with the digital transformation of law and of the public sector. The field has two main focuses. On the one hand, it investigates how new technologies can be applied to directly transform law and public administration. Classic examples include legal databases, ejustice, IT forensics, and the digitalization of public services. On the other hand, it investigates how to create appropriate legal frameworks to regulate new technologies, including data protection law, data governance, and AI regulation. The track aimed to join contributions not only to practical applications but also to the theoretical foundations of legal informatics, including the field of privacy (policies, regulations, strategies, recommendations), models of legal and ethical knowledge (especially with respect to core concepts such as 'norms', 'arguments', 'rules', 'cases', 'principles', 'values', 'procedures'), smart contracts, legal interactions of autonomous agents, digital institutions and both the practice and the foundations of the various areas of information law, and legal informatics with respect to social cohesion and the reduction of inequality.

Abstract. Representing legal norms by means of an adequate formalism is essential for the development of legally compliant autonomous systems. The remarkable variety of both formalisation and implementation frameworks proposed during the last decades enables the development of relatively efficient formalisations over a wide range of applications. Notwithstanding, this abundance of frameworks also leads to some practical problems, especially with respect to the integration of – or the translation between – different frameworks. While more or less widely applicable meta-formalisms are already available, they are often too complex and counter-intuitive, thus being clearly closer to the technical implementation than to the conception phase of the formalisation process. As a complementary, more human-oriented solution to the problem, the paper at hand introduces and discusses a more intuitive normal form structure, which is based on elements of legal theory and aims at facilitating the interdisciplinary communication among the many partners involved in the process of developing law-abiding machines.

1. Introduction

Current advancements in the field of artificial intelligence are paving the way for the integration of autonomous systems in various areas of human activity. Autonomous agents can recommend products, steer vehicles or assist in solving difficult formal problems. Within public administration, such systems can be employed to promote the automatisation of public services, to assist public authorities in making decisions under their jurisdiction, and enhance the administration of public goods in general (cf., e.g., Dolata and Schwabe, 2023; Döring et al., 2024; Larsen and Følstad, 2024; Lindgren, 2024). In the realm of law, autonomous systems can also be employed to provide more accurate information concerning the legal aspects of specific cases – thus promoting a better access to justice –, to assist judges, lawyers and other legal practitioners in their work or also to facilitate online dispute resolution (cf., e.g., Carneiro et al., 2014; Raabe et al., 2012; Virkar et al., 2022). Whilst the main objective of these systems is to be effective and efficient in solving the respectively given problems, especially when they are supposed to directly interact with humans, they should also behave

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

in a law-abiding manner. Thus, beyond being merely effective and efficient, autonomous systems should also be lawful.

The challenges involved in achieving law-abiding autonomous systems has lead to the development of various eclectic logical formalisms and implementation frameworks (for example, *LegalRuleML*; cf. Palmirani et al., 2011). However, these frameworks are oftentimes designed from an engineer's point of view and are thus less intuitive to legal scholars and practitioners. This often leads to difficulties in the interdisciplinary task of formalising legal norms. To provide a method for the specification of these problems in a way intuitive for both engineers *and* legal professionals, the paper at hand presents a type of *normal form* for representing legal norms based on elements of legal theory. Starting with high-level descriptions, this normal form allows for a swift transition between various degrees of specification, thus facilitating the communication between actors in the many implementation layers involved when designing autonomous systems. A further advantage of the normal form presented here is the fact that it can be easily combined with so-called *normative diagrams*, thus also enabling the construction of intuitive visualisations for the logical formalae employed.

In the following, Sec. 2 gives a short introduction to the general task of formalising legal norms using an example from German traffic law and demonstrates the various problems that may arise in the formalisation process. Sec. 3 briefly discusses related work on existing widely applicable meta-formalisms for legal norms and on the field of legal visualisation. Sect. 4 then presents the here proposed normal form solution and discusses how its structure facilitates the employment of a geometric visualisation method for legal norms by means of so-called *normative diagrams*. These diagrams could be particularly useful, e.g., if integrated in an intuitive *legal norm formalisation tool* directed at supporting legal scholars when formalising norms. Sec. 5 illustrates the use of the normal form (and of normative diagrams) through the discussion of a detailed example. Finally, Sec. 6 concludes and points out further directions for future research.

2. Formalising Legal Norms as a Complex Interdisciplinary Task

The process of formalising legal norms consists of several steps and involves experts from different disciplines. The complexity and interdependencies of this process can be illustrated through the example of developing an autonomous vehicle (AV). Designing an AV that is capable of driving *safely* through a city – a rather challenging task for itself – is not enough. Beyond *safety* requirements, AVs also have to fulfil *legal* requirements, i.e., they have to comply with existing traffic rules. In fact, some countries have already passed legislation requiring AVs to be able to autonomously comply with traffic rules, e.g., Germany's *Straßenverkehrsgesetz* (*StVO*)in its § 1e (2).

In a nutshell, the formalisation task consists of implementing traffic rules for AVs so that they are able to obey them like humans do. But to autonomously comply with legal norms, these norms must first be adequately *represented*. In particular, the representation method employed should enable AVs to recognise (ideally in advance) which manoeuvres they could perform would constitute a violation of a given legal norm. Moreover, in more *difficult* cases, e.g., in so-called *contrary-to-duty* situations or in cases involving conflicting norms (in which the violation of at least one norm is unavoidable), AVs should (ideally) be able to adequately evaluate and choose those manoeuvres which constitute lesser violations. Thankfully, literature offers countless formalisms – e.g., different systems of (deontic) logic (Gabbay et al., 2013) – which promise to deliver a more or less accurate representation of the various types of reasoning involved in such scenarios. However, the task of developing law-abiding AVs is not solely a logic problem, and it neither begins nor ends with the choice of an adequate formalism. Consider, e.g., the situation illustrated in Fig. 1. The autonomous vehicle AV is driving in Germany on the road r, which is partially obstructed by some unidentified object $\mathfrak{O}$. AV could drive on by performing the manoeuvre m_1 that would lead it through the indicated trajectory. As an autonomous system, AV should be able to determine whether is is allowed to do so.

At first glance, the case seems to be regulated by § 6 of the German Road Traffic Regulation (*StVO*). § 6 regulates a manoeuvre-type called *passing* (*Vorbeifahren*). It states that drivers wishing to *pass* (because of a road narrowing, an obstacle on the carriageway or a stationary vehicle) by driving onto the left lane must allow oncoming vehicles to pass through. A simple way to represent this in first-order logic would be:

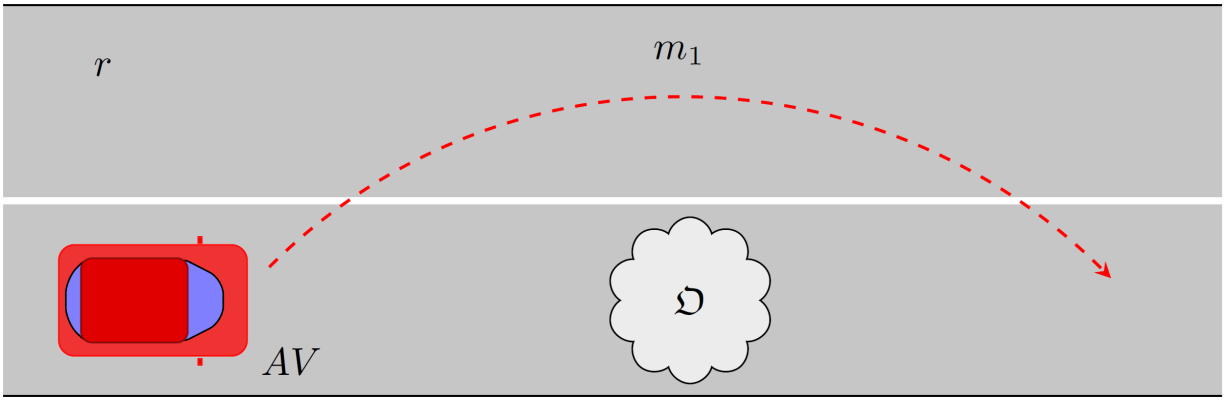

Fig. 1 – Would it be allowed for AV to drive past the unidentified object $\mathfrak{O}$ by taking the indicated trajectory?

$$\begin{aligned}&\forall x, y, z(\\&(Driver(x)\\&\wedge (Rd_Narrowing(y) \vee Obstacle(y) \vee St_Vehicle(y))\\&\wedge Onc_Vehicle(z, x)\\&\wedge Passing(x, y)\\&) \rightarrow Must_Allow_Pass_Through(x, z))\end{aligned} \quad (1)$$

Here, the predicate $Driver$ represents the property of being the operator of a vehicle (e.g., a human driver or an autonomous driving system). $Rd_Narrowing$, $Obstacle$ and $St_Vehicle$ are predicates corresponding to the conditions stated in § 6 StVO: They indicate that the driving situation is such that the lane in which one is driving is obstructed either by a road narrowing, an obstacle or a stationary vehicle. $Onc_Vehicle$ corresponds to the property of being a vehicle driving on the opposite lane. $Passing$ corresponds to the fact that a driver intends to perform the passing manoeuvre as defined in § 6 StVO. Finally, $Must_Allow_Pass_Through$ corresponds to the obligation that a driver intending to perform the passing manoeuvre has to first let oncoming traffic pass through. The variables x, y and z are assumed to be ranging over adequate sets of objects (e.g., drivers for x, road obstacles for y, vehicles for z).

Evidently, $Driver(AV)$ holds, and, at least intuitively, $Obstacle(\mathfrak{O})$ also seems to be satisfied. Hence, as long as there are no oncoming vehicles, it would seem that AV is allowed to execute the manoeuvrer m_1. In case there were oncoming vehicles, AV would only be allowed to perform m_1 if this were not to impede said vehicles from passing through, i.e., so as to satisfy $Must_Allow_Pass_Through(AV, z)$, where z is an oncoming vehicle.

However, a more careful consideration of the example depicted in Fig. 1 reveals that the road r, on which AV is driving, bears a specific road marking, namely a *solid line*. The legal norm connected to this road marking is described in the second annex to § 41 (1) of the StVO (*sign 295*). Following this norm, a vehicle driving on a road with a solid line must neither cross nor even straddle the line. A simple first-order formalisation of this norm would be:

$$\begin{aligned}&\forall x, y(\\&(Driver(x)\\&\wedge R_Sld_Line(y)\\&\wedge Drives_On(x, y)\\&) \rightarrow (Must_Not_Cross_Line(x)\\&\wedge Must_Not_Straddle_Line(x)))\end{aligned} \quad (2)$$

Since $Driver(AV)$, $R_Sld_Line(r)$ (road has a solid line) and $Driver_On(AV, r)$ hold, AV must neither cross nor straddle the solid line on r. Since, as implied by Fig. 1, performing m_1 requires crossing the solid line, the manoeuvre would actually be forbidden. This would mean that AV would have to wait behind $\mathfrak{O}$ until the carriageway is cleared or at least until it is able to pass by $\mathfrak{O}$ *without* crossing or straddling the line (Helle, 2021, Rn. 14). Formalisations (1) and (2) are, however, still far from ideal. Overall, they display two general problems, namely a *legal-theoretical* and a *technical* one.

The *legal-theoretical problem* consists in the fact that formalisations (1) and (2) do not really consider the valid *legal norms* applicable to the case, but only (some parts of) the corresponding *legal texts*. Formalisation proceeds from the assumption that law is a system of legal norms. From this perspective, it is important to distinguish between the law itself and its many sources, in particular between the law and written legislation (Nawiasky, 1948). Overall, legal norms are obtained from legal sources through the use of different interpretation techniques (Alexy, 1994, pp. 42-47, Weinberger & Weinberger, 1979, pp. 108-112). One can distinguish between five different classes of legal sources (for a more detailed discussion, cf., e.g., Kelsen, 2017, pp. 417-423, Bobbio, 1993, pp. 173-182): (I) written legislation; (II) legal precedents; (III) private autonomy (e.g., contracts, wills etc.); (IV) usages and customs; (V) legal dogmatics (e.g., the opinion of legal scholars). Hence, assessing the actual *norms* applicable to a given case requires way more than simply reading the text of written legislation. This is illustrated well by the fact that the last assessment given above, i.e., that AV would have to wait behind $\mathfrak{O}$ due to the solid line, is actually wrong. Following a well-established understanding adopted by German courts, a driver passing an obstacle in the sense of § 6 of the StVO is allowed to cross the solid line (Helle, 2021, Rn. 14; cf. also the court decisions OLG Saarbrücken, decision from 01.12.2016, 4 U 109/15, Rn. 47; OLG Düsseldorf, decision from 07.06.2022, I-1 U 222/20 Rn. 61). In other words, § 6 entails an (*unwritten*) exception to the solid line rule. The importance of interpretation becomes even clearer when considering the vagueness of the concepts used in § 6. For example, the predicate $Obstacle$, as represented in (1), could, intuitively, be satisfied *prima facie* by anything standing on the carriageway. Yet a more careful consideration of how legal dogmatics defines the concept of *passing* reveals that a non-stationary vehicle (or even a vehicle that stopped due to the traffic circumstances (Helle, 2021, Rn. 6, Heß, 2022a, Rn. 2-3) would not qualify as an obstacle in the sense of this norm. In other words, one does not *pass* by a non-stationary vehicle, one *overtakes* it. In the StVO, passing and overtaking (*Überholen*) are two different manoeuvres. Overtaking is regulated in § 5, and, more importantly for the case at hand, it does *not* constitute an exception to the solid line rule (Heß, 2022b, Rn. 92; cf. also the decision BGH NJW-RR 1987, 1048, 1049). Hence, whether or not AV is allowed to execute the manoeuvre m_1 depends on what exactly the object $\mathfrak{O}$ is.

This leads to the second, *technical problem* raised by formalisations (1) and (2): such formalisations have to be *implemented* in real machines, which leads to a series of challenges. For example, the predicates employed in formalisations of legal norms are often not logically independent from one another. For example, if r is a road with a solid line, i.e., if $R_Sld_Line(r)$ holds, then r cannot be (at least in the same segment) a road with a double centre line comprising one continuous and one broken line (*sign 296*); if z is a stationary vehicle, z cannot be a non-stationary vehicle etc. These inter-dependencies are usually represented by using so-called *ontologies* (Leone et al., 2022; Van Engers et al., 2008), which are basically first-order theories containing the rules of these inter-dependencies. In theory, such ontologies should be as detailed as possible, so as to be able to represent all the relevant factors included in legal norms. For example, following German courts and legal dogmatics, the minimal distance a driver must observe when passing by a stationary vehicle depends on several factors such as the width of the road, the type of the stationary vehicle, and whether there are visible people inside it or not. Ideally, one should employ an ontology containing all these concepts. Yet, using overly detailed formalisms might lead to implementation problems. In its core, verifying the legality of a manoeuvre with respect to a set of formalised norms is reducible to a *SAT problem* (or rather to a *satisfiability modulo theories* problem, cf. Lin & Althoff, 2022), i.e., checking whether a set of propositions is jointly satisfiable under a set of assumptions. However, SAT problems belong to the category of computationally expensive, so-called *NP-complete* problems. In general, adding more details to the formalism will lead to an exponential growth of the computational power required to verify the legality of a manoeuvre, which will quickly overwhelm even the fastest of modern computers. This is particularly problematic because, ideally, an autonomous vehicle should be able to consider various possible manoeuvres and trajectories in a relatively short amount of time, instead of analysing only one possibility *ad nauseam*. Moreover, an autonomous vehicle would not only have to be able to operate with all these concepts, but also to *detect* the existence of corresponding objects in its environment. In the example illustrated in Fig. 1, before it could even begin assessing the legality of following the trajectory m_1, AV would have to detect that it is driving on a road with a solid line and that there is an object $\mathfrak{O}$ obstructing its path. Then, it would have to determine what kind of object $\mathfrak{O}$ is. If it is a stationary vehicle, it would have to detect what kind of vehicle it is, and whether there are visible people inside it etc., which would require considerable computational power.

These examples show that formalising legal norms for the development of law-abiding machines is a complex interdisciplinary task. Legal norms are not just simply derived from written legislation. With the increasing degree of detail given in a formalisation, the computational resources for the calculation of the corresponding reasoning problems might also increase drastically. The formalisation process itself starts with legal scholars

delivering a description of what the law actually is, i.e., of the legal norms proper, it continues with logicians representing these norms in a logical formalism, and ends with computer scientists and engineers implementing this formalism in a practically feasible manner. This interdisciplinary work-flow is illustrated in Fig. 2.

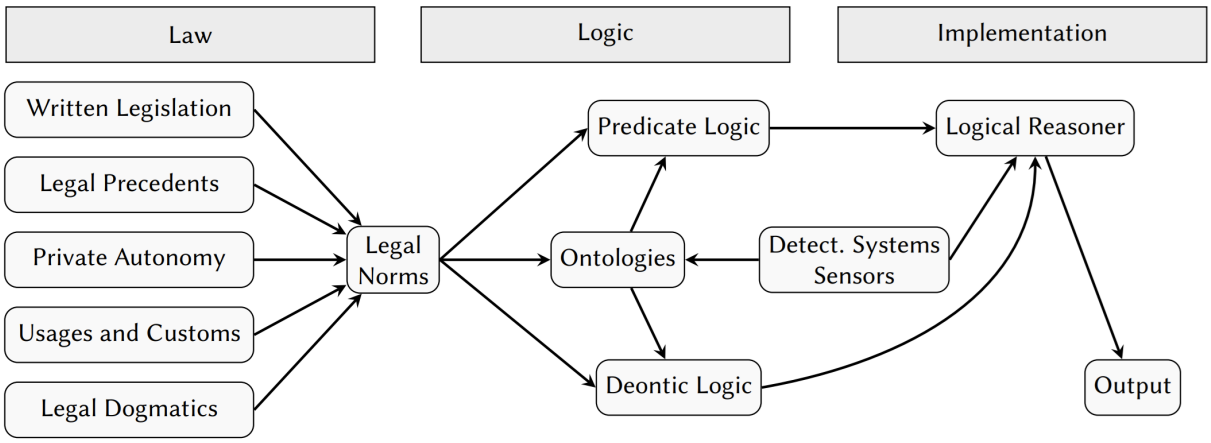

Fig. 2 – Representation of the work-flow from the analysis of the sources of law to the final implementation of legal norms in a law-abiding machine.

In this process, logicians see themselves caught between the need to adequately formalise the scientifically accurate norm descriptions given by legal scholars and the practical requirements and limitations determined by computer scientists and engineers. In particular, legal scholars tend to prefer a wider, *open-texture* formalisation, i.e., one that employs vague general concepts, thus being closer to a natural-language description of the respective norms. Computer scientists require variables and constants pertaining to a given domain to be assigned to these concepts, and engineers require these variables and constants to correspond to real-world objects which they can effectively detect. Hence in practice, more often than not, the formalisation first agreed upon between the involved parties has to undergo several modifications before it can actually be implemented. Furthermore, the use of many different formalisms and systems, e.g., formal languages, ontologies, logical reasoners, theorem provers, detection and driving systems along these different steps, with each possibly being based on different abstraction levels, often requires translating from one formalism into the other. This could eventually result in unnoticed errors, especially since the various employed formalisms might differ in their inherent expressiveness. Finally, having to constantly translate between formalisms also hinders the interdisciplinary communication between the many partners involved in developing law-abiding autonomous systems.

3. Related Work

Representing legal norms in a *normal form* constitutes a promising solution to the problems discussed above, as this could greatly simplify and unify the formalisation process with its various existing frameworks. As long as this normal form is at least partially based on elements of legal theory, it could also present a middle ground for legal professionals, logicians, computer scientists and engineers. In the following, Sec. 3.1 briefly discusses already existing widely applicable meta-formalisms for representing legal norms and their shortcomings with respect to interdisciplinarity. Sect. 3.2 then briefly discusses related work in the field of legal visualisation.

3.1. Meta-Formalisms for Legal Norms

Eclectic *meta-formalisms* for representing legal norms – i.e., symbolisms applicable to a wide range of underlying logical formalisms – already exist. For example, especially if norms are represented using (variations of) classic predicate logic, in particular first-order logic, one could employ the symbolism of the *Thousands of Problems for Theorem Provers (TPTP)* library (Sutcliffe, 2017). Beyond its overall flexibility, the TPTP-symbolism is both fairly easy for humans to read and compatible with PROLOG, which facilitates further implementations. Another good example is *LegalRuleML* (Palmirani et al., 2011), an XML-based annotation framework capable of directly representing legal norms and several properties usually associated with normativity, especially *defeasibility*. One could also, as proposed by Steen and Fuenmayor, 2022, attempt to combine

both TPTP and LegalRuleML. However, while these meta-formalisms are extremely useful, they were evidently crafted with the implementation part of the process in mind. For the average legal scholar – and even for logicians and technicians not used to working with them –, they remain relatively complex and unintuitive. Hence, they do not facilitate the interdisciplinary communication between legal scholars, logicians, computer scientists and engineers. The normal form discussed here aims at filling this gap. It is far more primitive than the remarkable meta-formalisms mentioned above, and it focuses more on didactic aspects, on clarity, and on promoting and facilitating communication between humans. Hence, it is obviously not conceived as an alternative to implementation-oriented meta-formalisms such as TPTP's language or LegalRuleML, but as a human-focused methodological complement to them.

3.2. Legal Visualisation

Furthermore, the normal form proposed here was designed to be employed together with the legal visualisation method of *normative diagrams* (Sasdelli & Trivisonno, 2023), which is introduced in more details below in Sec. 4.2. Combining a textual formalism (like the normal form) with a visual one (like the diagrams) offers several advantages. Legal visualisations can be defined as human-oriented, (semi-) formal, pictorial (rather than verbal) knowledge management structures or *visual representations* in a general sense (Cyras & Lachmayer, 2023). Overall, depending on the goal pursued, visualisations found in the literature display different degrees of abstraction and formalism. Less formalised or structured imagery is usually employed for didactic (especially mnemonic) purposes (e.g., McCloskey, 1998), as well as for communication with children (Kessel, 2014), laymen (Carnein et al., 2014) and the public in general (e.g., in the context of the so-called *Proactive Law Movement* and *Legal Design*; cf. Murray, 2021); for an overview, cf. also Brunschwig, 2014. More formal methods, e.g., decision trees, graphs and the normative diagrams discussed here, are used not only within legal higher education, but also for theoretical and practical purposes (Kohlhase et al., 2021; Muff & Fill, 2021; Röhl & Ulbrich, 2007; Sasdelli & Trivisonno, 2023). As an intermediate abstraction level between natural language and a logical formalism (Lachmayer & Cyras, 2021), visualisations also constitute a valuable extension to legal tech applications, by facilitating both the interdisciplinary communication during the development of such applications as well as their later use by legal experts and the public in general. A good example is the PROLOG-based practical legal reasoning system PROLEG (Satoh, 2023), which in more user-friendly implementations also generates a decision tree diagram illustrating the reasoning process leading to the decision derived by the program. A new trend in the field involves the usage of virtual reality tools (Muff & Fill, 2021; Muff et al., 2022).

4. Normal Form and Normative Diagrams

The following Sec. 4.1 gives an in-depth description of the proposed normal form and also considers its advantages in light of different existing legal formalisms. Sec. 4.2 shows how *normative diagrams* can be used to visualise the normal form and thus further facilitate the comprehension for the involved parties of the formalisation process.

4.1. Normal Form Structure and Theoretical Background

In general terms, one can distinguish between two main types of legal norms (Kelsen, 1979, pp. 76-78):

1. Norms that refer to the validity of other norms, e.g., procedural law, norms regulating the legislative process and derogative norms;
2. Norms that refer directly to the actions or to the overall behaviour of agents.

In the following, only norms of the latter type shall be considered. Such norms can be further subdivided into three categories: (1) prohibitions, (2) obligations, and (3) permissions (Kelsen, 1979, pp. 76-77, Bobbio, 1993, pp. 96-99). Each of these categories is connected to different violation conditions. Prohibitions, for example, are violated when a case corresponds to the norm's content or, in case of analogy, when a case is sufficiently similar to the norm's content. Determining the violation conditions for obligations is a more difficult task. Generally speaking, it seems reasonable to assume that obligations are violated when it becomes impossible to satisfy the norm's content. This would indicate an important temporal element to the definition of the violation conditions of obligations, which, however, would become a challenge when considering obligations

that can never be completely fulfilled (even without being thus necessarily violated). Examples would be very general legal or moral principles, in particular so-called *imperfect duties* (Johnson & Cureton, 2024), like the duty to respect human dignity, the duty to live a healthy life etc. Further challenges concerning the definition of the violation conditions of obligations could arise from the concept of supererogation, i.e., roughly speaking, doing more than one's duty actually requires (Heyd, 2023; Wessels, 2002). For simplicity, in the paper at hand, it shall be assumed, as it is done in some works of legal theory (cf., e.g., Kelsen, 1979), that obligations can be reformulated as prohibitions. Finally, Permissions cannot be violated.

Intuitively, norms regulate sets of actions or behaviours that:

- belong to specific action or behaviour categories;
- happen at a given place;
- are performed by specific agents;
- transpire at a specific point in time.

Hence, irrespective of its category, the content or *validity domain* of a norm can be seen as stretching throughout four *dimensions*: object (O), space (R), subject (S) and time (T) (cf. Bobbio, 1993, p 214, Kelsen, 1979, pp. 116-119, Nawiasky, 1948, p. 85). When considering only prohibitions, the most obvious violation condition of a norm coincides with a description of its validity domain in the four dimensions mentioned above: a case will constitute a violation to the norm if it falls (or is subsumed) under its normative content or validity domain, i.e., if it is subsumed under the category of actions which the norm directly state as being prohibited. Further violation conditions could still be derived, e.g., by considering analogy arguments. Setting analogies aside and focussing on subsumption, the conditions for the violation V_ϕ of the norm ϕ can be determined by:

$$V_\phi \Leftarrow (O_\phi \wedge R_\phi \wedge S_\phi \wedge T_\phi) \tag{3}$$

Where $\Leftarrow$ is a *necessary condition* operator and O_ϕ, R_ϕ, S_ϕ and T_ϕ are high-level descriptions respectively of the objective, spacial, subjective and temporal dimensions of the norm ϕ's validity domain.

The structure of the equation (3) can be used as a normal form for logic-based representations of legal norms. This claim is based on the assumption that every norm can be adequately represented by its violation conditions. This is fairly obvious, under the assumptions made above, for prohibitions and obligations. For *permissions*, which, as stated above, cannot be violated, it seems reasonable to establish the convention that their representation in this normal form corresponds to an empty expression. This means that permissions will be basically ignored, except when dealing with them as exceptions to other norms. This should not constitute a problem for the applications discussed here: when developing a law-abiding autonomous agent, it is more convenient to only keep track of the actions which the machine should avoid, i.e., of which actions constitute violations – all other actions (which are evidently way larger in number) can then be considered to be permitted. Moreover, permissions constituting exceptions to prohibitions or obligations can be considered as (partial) *derogations*, i.e., as limitations of a norm's violation conditions.

The normal form promotes a natural formalisation process. One first starts with the high-level descriptions O_ϕ, R_ϕ, S_ϕ and T_ϕ of the violation conditions of the norm ϕ, which basically just state that the conditions for a case to fall under the norm's validity domain and thus be violated (if the norm is a prohibition norm) are satisfied. Then, one can, by means of interdisciplinary work between legal scholars, computer scientists and engineers, introduce further, more detailed descriptions of the circumstances that satisfy each of these high-level descriptions. The possibility to reduce such different formalisms back to one and the same normal form demonstrates the flexibility of the presented method. Since each high-level description is directly associated with one of the norm's validity dimensions, using the normal form leads to a better organisation of the formalisation work. Ideally, one would then be able to more easily identify which elements of the legal norm (as described by legal scholars) cannot (yet) be efficiently processed or detected by the available methods employed (as determined by computer scientists and engineers). This could facilitate the search for approximations or other alternative solutions.

Finally, besides being based on the legal-theoretical division of a norm's validity domain in four dimensions, the normal form presented here was also conceived to be easily combined with existing formalisms like the ones just mentioned above. For example, the necessary condition operator $\Leftarrow$ was chosen because of the long tradition of using *horn-clauses* to formalise legal norms in PROLOG or related formalisms (cf., e.g., Satoh, 2023; Sergot et al., 1986). Due to its relatively simple structure, it can be easily combined with any formalism based

on predicate logic, especially with temporal logics (Maierhofer et al., 2022). The normal form can also be combined with formalisms based on modal logic, especially with deontic logic (Gabbay et al., 2013). This can be done, e.g., by conditioning the fulfilment of one or more predicates on the satisfaction of formulae under given conditions represented in the desired formalism. Overall, the normal form offers an elegant way of both organising the designed formulae and guiding the further development of the formalisation process, while also enabling a combination of various different formalisms. This can be employed to determine adequate conditions for the satisfaction of the respective predicates culminating in the normal form's four conjuncts.

4.2. Enhancing the Normal Form with Normative Diagrams

Like the normal form presented here, normative diagrams are also based on the idea that a norm's validity domain extends over four dimensions. By assigning each dimension to an axis in a coordinate system, the validity domain of a norm can be represented as a region in a four-dimensional metric space. For example, if it is assumed that the action of crossing or straddling a solid line is delimited by the values o_1 and o_4; the set of all German roads with solid lines by the values r_1 and r_3; the set of all drivers by the values s_1 and s_2; and the set of all possible points in time by $\{t_x | x \in \mathbb{N}\}$, then the validity domain U_ψ of the norm associated with sign 295 of the German StVO (let this norm be called ψ) can be defined as being the set:

$$U_\psi = \{ < o_a, r_b, s_c, t_d > \mid o_a \in [o_1, o_4] \wedge r_b \in [r_1, r_3] \wedge s_c \in [s_1, s_2] \wedge t_d \in \{t_x | x \in \mathbb{N}\} \} \tag{4}$$

Since the norm is valid at all points in time, i.e., it is *always* prohibited to cross or straddle the line, the temporal dimension can be omitted. Hence, it is possible to represent the norm ψ in a three dimensional normative diagram, as illustrated in Fig. 3. The region delimited by the red three-dimensional figure corresponds to ψ's validity domain. Here, the colour red is used to indicate that ψ is a prohibition norm. Similarly, the colours blue and yellow can be used to represent obligation and permission respectively. Concrete cases can be depicted as points in this three-dimensional metric space. Since the norm ψ is a prohibition, if a point is located inside of the three-dimensional cuboid of the norm, the corresponding case falls under its validity domain and thus *violates* the norm. Hence, the violation conditions specified by the *normal form* can be easily visualised through respective normative diagrams, while the concrete values on the axes can help in defining the normal form for a norm.

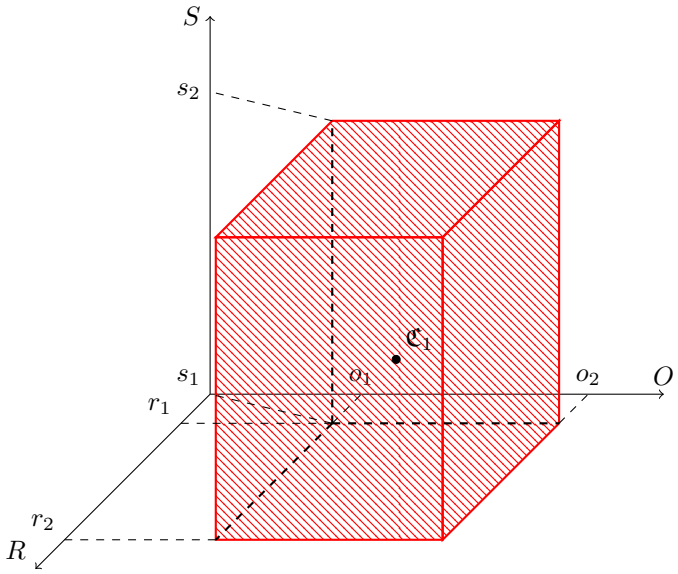

Fig. 3 – A three-dimensional normative diagram for the norm ψ with case $\mathfrak{C}_1$ violating the norm.

For simplicity, one could also restrict the analysis of the subjective dimension of the norm's validity domain to the set of all *drivers*. In this case, it would be possible to also omit the subjective dimension of the norm's validity domain; for it is in fact prohibited for *all drivers* to cross or straddle the solid line. In this case, a two-dimensional representation would suffice (left side of Fig. 4). Finally, one could also restrict the analysis to the set of roads with solid lines, because, evidently, one can only cross or straddle these lines while driving on roads that have them. Hence, the norm could also be adequately represented with a one-dimensional diagram containing only the objective dimension (right side of Fig. 4).

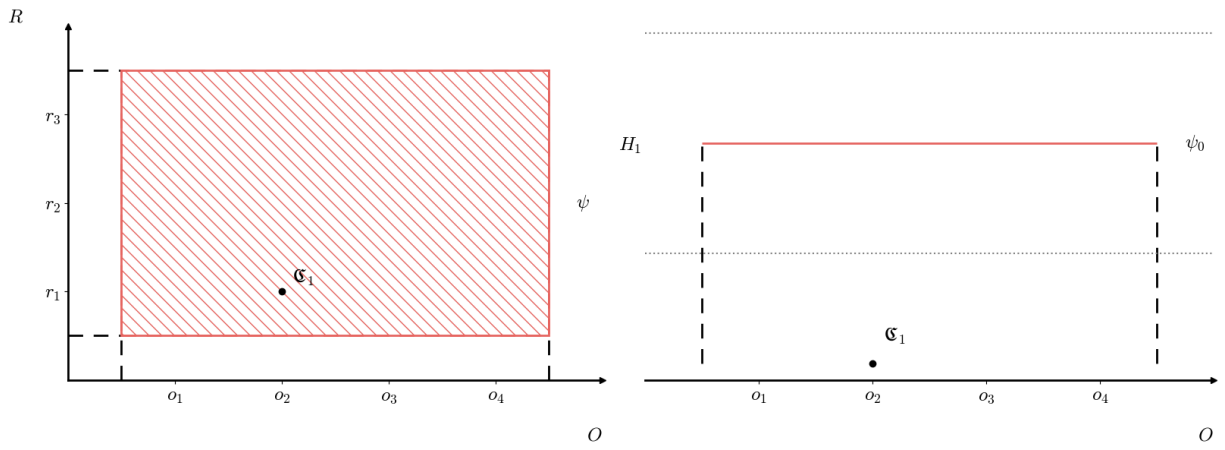

Fig. 4 – Simplified diagrams for ψ with two dimensions (left) and with one dimension (right), each with case $\mathfrak{C}_1$ violating the norm.

The *unwritten* exception to the solid line norm which allows drivers to cross the line when passing by a road narrowing, an obstacle or a stationary vehicle in the sense of § 6 of the StVO can be represented by adding a second norm ζ to the diagram, as shown in Fig. 5. Since the validity domains of the norms intersect, i.e., since $U_\psi \cap U_\zeta \neq \emptyset$, and since the norms differ in their mode, i.e., ψ is a prohibition and ζ is a permission, these norms constitute a *normative conflict* or a (legal) *antinomy* (Bobbio, 1993, pp. 209-216, Engisch, 1985, p. 160). Moreover, since $U_\zeta \subset U_\psi$, this conflict is of the type *total-partial*, and can thus be solved by the classic speciality criterion (*lex specialis derogat legi generali*). When representing the antinomy between ψ and ζ, it is useful to employ a two-dimensional diagram (left side of Fig. 5), because one could argue that the exception contained in ζ does not apply to all roads with solid lines, but only to those which are wide enough to allow for the vehicle to pass through.

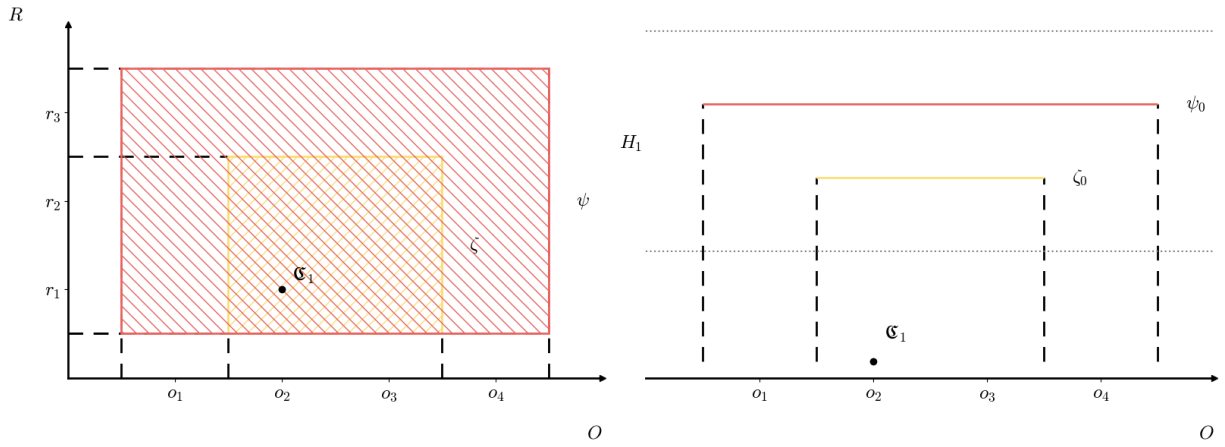

Fig. 5 – The unwritten exception to the solid line norm can be represented as a legal antinomy between the norms ψ and ζ. The values between o_2 and o_3 correspond to the action of crossing a solid line while passing by an obstacle, a road narrowing or a stationary vehicle in the sense of § 6 of the StVO. The values between r_1 and r_2 represent those roads that are wide enough to allow for the manoeuvre to be performed. Evidently, this will depend on the object obstructing the way and on the width of the passing vehicle.

Normative diagrams can also be employed to represent legal arguments, e.g., analogy, appeals to the contrary, as well as more complex aspects of legal norms, e.g., their hierarchy level in the legal order (for details, cf. Sasdelli and Trivisonno, 2023). Alternative representation forms that allow the complete visualisation of all four dimensions of the validity domain in one single figure have also been developed (Steffes & Sasdelli, 2025). Being a simple but nonetheless efficient way of visualising legal norms and other legal phenomena, these diagrams could constitute a valuable component in a user-friendly *legal norm formalisation tool*. This tool could be employed in a wide range of different applications, e.g., for research and development purposes in the

area of law-abiding autonomous agents or for didactic purposes in law faculties or in the field of legistics. Such tool could be developed on the basis of ViNo, an open-source tool[1] that automatically generates normative diagrams from given inputs (a prototype was presented by Steffes and Sasdelli, 2024).

5. Example

This section now presents a precise example on how to apply the presented normal form with a particular focus on its combination with normative diagrams. For this example, the manoeuvre m_1 depicted in Fig. 1 shall be considered again.

The legality of m_1 depends on a set of norms $\mathfrak{N}$ containing the norms applicable to m_1. In this case, it consists of the norms corresponding to sign 295 and to § 6 of the German Road Traffic Regulation, as well as further prescriptions such as speed limits or norms related to the general obligation to drive carefully and to be mindful of other road users (§ 1 of the German Road Traffic Regulation). For simplicity, assume $\mathfrak{N} = \{\psi,\ \chi,\ \kappa\}$, i.e., $\mathfrak{N}$ contains only the three norms ψ, χ and κ. These norms correspond respectively to the prohibition of crossing the solid line (sign 295, ψ), to the regulation of the manoeuvre-type *passing* (§ 6, χ), and to the speed limit of road r, which can be assumed to be 30 km/h (κ). In the normal form, each of these norms can be represented through the expression

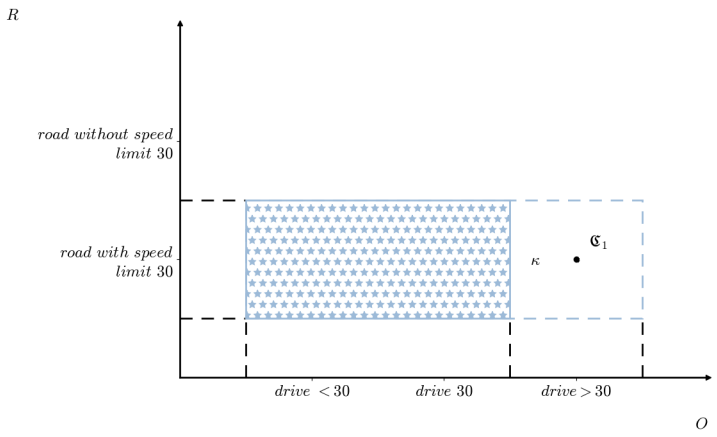
$$V_x \Leftarrow (O_x \wedge R_x \wedge S_x \wedge T_x). \tag{5}$$

Assuming $[m_1]$ to be a comprehensive description of the manoeuvre m_1 in some logic formalism, checking whether the manoeuvre m_1 is legal can be reduced to the task of checking whether the expression

$$(O_x \wedge R_x \wedge S_x \wedge T_x) \Leftarrow [m_1] \tag{6}$$

is satisfied for any $x \in \mathfrak{N}$. Following the structure of the normal form, the expression $[m_1]$ can be further divided in the subformulae O_{m_1}, R_{m_1}, S_{m_1} and T_{m_1} which each contain the predicates for detecting a violation in one of the four dimensions:

$$(O_x \wedge R_x \wedge S_x \wedge T_x) \Leftarrow (O_{m_1} \wedge R_{m_1} \wedge S_{m_1} \wedge T_{m_1}) \tag{7}$$

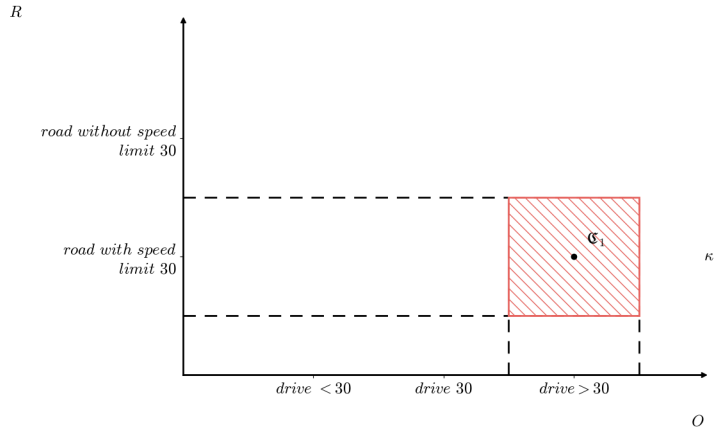


For this, it is first necessary to further define both $[m_1]$ and the norms in $\mathfrak{N}$. In particular, a more detailed definition of the norms in $\mathfrak{N}$ – to be provided by legal scholars – should clarify which kinds of information $[m_1]$ should ideally contain – i.e., as provided by the sensors of an AV – to determine the violations.

The speed limit κ can be assumed to be valid at all times for all subjects with respect to all manoeuvres they perform. Thus, the norm is violated by all manoeuvres performed while driving faster than 30 km/h on road r (this ignores, for the sake of simplicity, the obvious exception given to emergency vehicles, e.g., ambulances). Hence, one can further specify the violation condition of κ by determining that $T_\kappa \Leftarrow \top$ and $S_\kappa \Leftarrow \top$ hold, where $\top$ is any logical tautology. For the further conditions, one can determine, e.g., $R_\kappa \Leftarrow Road_{30}(m)$ and $O_\kappa \Leftarrow f_{speed}(m) > 30$, where m is a variable ranging over all possible manoeuvres, $Road_{30}$ is a predicate that is satisfied if and only if a manoeuvre is performed on a road with a speed limit of 30 km/h, and f_{speed} is a function that retrieves the maximum speed of a given manoeuvre.[2] These thoughts are illustrated with example values in Fig. 6 when considering κ to be an obligation, i.e., the obligation of driving in a speed below the set limit. Following the assumption made above that an obligation may also be generally reformulated as a prohibition, Fig. 7 depicts the norm as a prohibition, i.e., the prohibition of driving in a speed above the set limit.

The solid line norm ψ can be likewise assumed to be valid at all times and with respect to all subjects. As discussed above, its spatial violation condition only refers to roads containing solid lines; hence, one can further determine $R_\psi \Leftarrow R_Sld_Line(m)$. At first glance, its objective dimension refers to all possible manoeuvres (e.g., overtaking, turning left, making a U-turn) that imply crossing or straddling the solid line. However, as discussed above, the norm corresponding to § 6 (*Passing*) of the German Road Traffic Regulation contains

[1] The code can be found at https://github.com/bs-000/norm-visuals. The repo also contains a Windows executable file to provide an easy access for technical laymen.

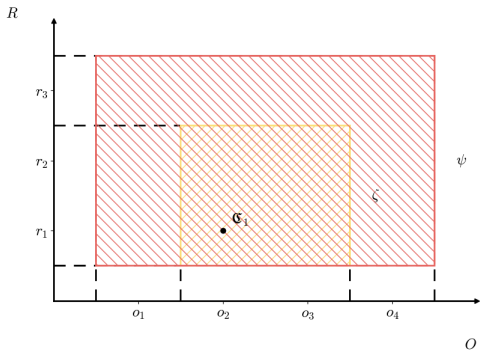


[2] Alternatively, one could replace the predicate $Road_{30}$ by a respective function f_{road} that retrieves the road (or rather, a road-index $[r] \in \mathbb{N}$ functioning as a name for the road) in which a given manoeuvre is performed. In this case, one would write the respective condition as $R_\kappa \Leftarrow f_{road}(m) = [r]$.

$$V_\kappa \Leftarrow (O_\kappa \wedge R_\kappa \wedge S_\kappa \wedge T_\kappa)$$

$$O_\kappa \Leftarrow f_{speed}(m) > 30$$
$$R_\kappa \Leftarrow Road_{30}(m)$$
$$(R_\kappa \Leftarrow f_{road}(m) = [r])$$
$$S_\kappa \Leftarrow \top$$
$$T_\kappa \Leftarrow \top$$

Fig. 6 – Diagram and normal form description of the speed limit of 30 km/h with κ as an obligation.



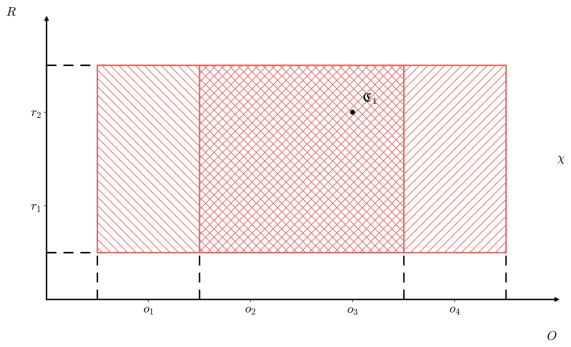
$$V_\kappa \Leftarrow (O_\kappa \wedge R_\kappa \wedge S_\kappa \wedge T_\kappa)$$

$$O_\kappa \Leftarrow f_{speed}(m) > 30$$
$$R_\kappa \Leftarrow Road_{30}(m)$$
$$(R_\kappa \Leftarrow f_{road}(m) = [r])$$
$$S_\kappa \Leftarrow \top$$
$$T_\kappa \Leftarrow \top$$

Fig. 7 – Diagram and normal form description of the speed limit of 30 km/h with κ as a prohibition.

an implicit exception to this rule: when performing the manoeuvre *Passing*, drivers are allowed to cross the solid line. Hence, one could determine $O_\psi \Leftarrow m \in \mathfrak{M}_{xsl} \backslash \{Passing\}$, where $\mathfrak{M}_{xsl} \backslash \{Passing\}$ is the set of all manoeuvres that imply crossing or straddling the solid line except the manoeuvre *Passing*. To visualise this rule-exception, one can interpret § 6 StVO to also contain (or at least imply) a permissive norm ζ, stating that it is allowed to cross or straddle the solid line when passing by. The resulting normative conflict between ψ and ζ would be solvable by the collision rule *lex specialis*, which, in effect, leads to the same result as stating that *passing* manoeuvres constitute exceptions to the general solid line rule. These thoughts are illustrated in Fig. 8.

Finally, a direct interpretation of § 6 StVO also entails an obligation norm χ, which regulates the *Passing* manoeuvre. This norm can be specified as follows. As it was the case with κ and ψ, χ's temporal and subjective violation conditions can be assumed to be always fulfilled. Its spatial condition concerns roads wide enough so that *Passing* is possible. Hence, one could determine: $R_\chi \Leftarrow Rd_Width_Ok(m)$. § 6 StVO stipulates that drivers passing by an obstacle have to allow for oncoming vehicles to pass through. Hence, by means of a still fairly high-level description, the objective violation condition could be specified as $O_\chi \Leftarrow Impedes_Onc_Traffic(m)$. Evidently, the predicates Rd_Width_Ok and $Impedes_Onc_Traffic$ are still too abstract to allow for meaningful practical implementations. Therefore, it would be necessary to further specify the conditions under which these predicates are satisfied. For example, one could further define $Road_Width_Ok$ as a function of the overall width of the road, the width of the vehicle performing the respective manoeuvre and the width of the obstacle in question. However, even after the addition of these specifications, this representation of the norm regulating the *Passing* manoeuvre would still be missing an important point: while this is not explicitly stated in the text of § 6 StVO, a deeper analysis of legal precedents and legal dogmatics reveals that *Passing* is only allowed when the manoeuvre is performed while observing a *minimal safety distance*, which depends on the circumstances of the concrete case. Hence, it would be more appropriate to represent χ's objective violation condition as $O_\chi \Leftarrow (Impedes_Onc_Traffic(m) \vee$



$$V_\psi \Leftarrow (O_\psi \wedge R_\psi \wedge S_\psi \wedge T_\psi)$$

$$O_\psi \Leftarrow m \in \mathfrak{M}_{xsl} \backslash \{Passing\}$$
$$R_\psi \Leftarrow R_Sld_Line(m)$$
$$S_\psi \Leftarrow \top$$
$$T_\psi \Leftarrow \top$$

Fig. 8 – Diagram and normal form description of the solid line rule ψ. The implicit exception derived from the *passing* rule is represented by ζ. Notice that, although they are both derived mainly from the same legal source (§ 6 of the German Traffic Road Regulation) ζ is different from χ.

$Violates_Safety_Distance(m)$). This is illustrated in Fig. 9.

$$V_\chi \Leftarrow (R_\chi \wedge T_\chi \wedge S_\chi \wedge O_\chi)$$

$$O_\chi \Leftarrow Impedes_Onc_Traffic(m) \vee Violates_Safety_Distance(m)$$
$$R_\chi \Leftarrow Rd_Width_Ok(m)$$
$$S_\chi \Leftarrow \top$$
$$T_\chi \Leftarrow \top$$

Fig. 9 – Diagram and normal form description of the norm χ regulating the *Passing* manoeuvre (§ 6 of the German Road Traffic Regulation). The area between $o_{1'}$ and $o_{1''}$ corresponds to manoeuvres that satisfy both predicates $Impedes_Onc_Traffic$ and $Violates_Safety_Distance$.

Likewise, it would be necessary to further specify the predicate $Violates_Safety_Distance$. According to legal scholarship, the *minimal safety distance* required when performing the manoeuvre *Passing* usually amounts to one meter (König, 2023, Rn. 7). However, depending on the circumstances, the required distance can also be wider or smaller. Among the most commonly considered examples are those in which the obstacle is another vehicle. *Prima facie*, a driver (or an AV) should detect the type of said vehicle, e.g., whether it is a truck, a bus or a car, whether one of its doors is open, or if there are people in the vehicle or around it. German judicial practice establishes more specific provisions concerning the minimal safety distance in such situations. For instance, in case a person is likely to exit or to open the door of a vehicle, drivers are usually expected to keep a distance of more than one meter when passing (Gutt, 2022, Rn. 14, König, 2023, Rn. 7)(cf. also Schauseil, 2011). Similarly, when passing by a bus, a garbage truck or construction machines, drivers have to take into account that people might suddenly walk onto the street. Hence, they are required to drive slow enough to be able to quickly stop if necessary, or to generally keep a larger safety distance, e.g., of 1,8-2 m (Heß, 2022a, Rn. 7-8, Bender, 2016, Rn. 8) (cf. also the decision BGHSt 13, 169). On the other hand, a distance of 50 cm may be enough if the road is particularly narrow (König, 2023, Rn. 7). These concrete standards could be implemented by individually assigning the respective safety distance to each manoeuvre, so that $Violates_Safety_Distance(m)$ is satisfied whenever the actual distance is smaller than the allowed distance. However, it is important to notice that these criteria are not absolute; they serve only as guidelines to help determine the minimal safety distance in a concrete situation.

This approach reveals a further problem: a review of the sources related to § 6 of the German Road Traffic Regulation can only reveal concrete requirements for a limited number of situations, i.e., the situations already considered by German courts or by legal dogmatics. Yet, specifying χ requires the definition of a safety distance for *all* possible situations. Thus, to avoid violating χ, the specific examples need to be generalized so

that safety distances are assigned to situations that have not been explicitly included. For example, case law and literature have not specifically addressed the distance required when passing a stationary delivery truck, which can be seen as analogous to passing a stationary garbage truck – since one could likewise expect that people might suddenly walk onto the street – and would therefore require a similar distance.

One approach to solving this issue is to gather characteristics of known cases and have the AV compare unknown cases to these standards. In the example above, the safety distance would then be the same as when passing a stationary garbage truck in all cases in which the sensory data for the obstacle and the surrounding pedestrians is sufficiently similar to the data associated with garbage trucks. Thus, an unlimited number of situations could be accounted for even with a limited number of sources. The assessment of a similarity predicate could be done by means of a logical formalism designed specifically for representing degrees of similarity and analogy. An example could be so-called *neighbourhood frames* (cf., e.g., Nortmann, 1989). A different approach could be to employ the visual form of the normative diagrams. If the values on each of the dimensions' scales can be comprised to a cardinal scale, distance measures like the euclidean distance or the Hamming distance may be employed to measure the similarity of different cases or the distance between a norm and a case. A smaller distance may be interpreted as a higher similarity. Of course, determining the optimal degree of similarity (in terms of both engineering and legal standards) and creating these orderings are challenging tasks that lie beyond the scope of the paper at hand.

6. Conclusion and Future Work

The normal form presented here is a valuable methodological tool for the complex and interdisciplinary task of formalising legal norms. Its structure allows for a multi-step and multi-level formalisation procedure. Starting with very high-level descriptions of the violation conditions of a norm – organised in a way that is based on legal theory, i.e., on the four dimensions of a norm's validity domain –, it facilitates that gradual further specification to more detailed descriptions. This framework is particularly flexible: with each further specification, a new formalism (e.g., different types of modal, temporal or deontic logic) may be employed according to the respective needs. Such a structure allows for a better understanding of the representation and implementation challenges one might face when formalising legal norms. Finally, especially when combined with normative diagrams, the normal form facilitates the visualisation of the legal norms to be formalised, as well as of more complex legal-theoretical phenomena.

An important future work topic concerns dealing with the formalisation of legal gaps, legal antinomies and of contrary-to-duty-situations within the framework of the normal form. In particular, situations in which at least one norm has to be violated, i.e., situations in which all possible manoeuvres in a set $\mathfrak{M}$ lead to some violation V_x of a norm $x \in \mathfrak{N}$, could be solved by establishing a priority degree between the violations. This priority degree could be based on elements of legal theory, e.g., the classic collision rules for solving legal antinomies (Bobbio, 1993, p. 218-222). A further topic for future work on theoretical aspects is the definition of specific criteria for determining the distance between different case-descriptions as well as between a case-description and a norm-description, which would serve as a basis for the formalisation of analogy arguments. Finally, more research on the particularities concerning the violation conditions of obligations (e.g., aspects concerning imperfect duties and supererogation) is also needed. Additionally, the visualisation of four-dimensional objects may be challenging to understand for humans as discussed by Steffes and Sasdelli, 2025. From a more technical perspective, the main topic for future work involves developing an interactive legal formalisation tool implementing the normal form framework presented, while also combining it with existing logical formalisms for legal knowledge representation and with methods of legal visualisation, e.g., with normative diagrams.

Submitted: 31 January 2025, Revised: 26 March 2025, Accepted: 21 April 2025, Published: 23 May 2025

Abstract. As digital transformation accelerates globally, the quality of national regulatory frameworks has become a key determinant of effective e-governance. This paper investigates how regulatory maturity influences the development and implementation of digital government initiatives across eight countries. It introduces a three-tier classification: advanced, moderate, and early-stage, based on the scope of legal frameworks, operationalisation of digital enablers, and integration into public service delivery. Countries such as Belgium, Estonia, and Singapore demonstrate that coherent and enforceable legal ecosystems when paired with institutional coordination and technical infrastructure, achieve high digital governance performance. By contrast, fragmented frameworks constrain implementation and trust. Using cross-case comparison and internationally recognised indices (e.g., EGDI, OSI, EPI, GCI), the study validates this classification and identifies recurring barriers such as regulatory lag, institutional misalignment, operational and infrastructure gaps, and societal mistrust. The findings confirm that while legal maturity is foundational, institutional capacity, technical readiness, and public engagement are critical for inclusive and resilient digital transformation.

Keywords. Digital governance, E-Governance, Regulatory Maturity, Legal Framework, Digital Transformation.
Research paper, DOI: https://doi.org/10.59490/dgo.2025.1037

1. Introduction

E-governance has emerged as a cornerstone of modern public administration (Gil-Garcia et al., 2018; Heeks, 2002). It leverages digital technologies to transform the way government operates (Bannister & Connolly, 2011a; Cordella & Bonina, 2012), enhance public service delivery (Meyerhoff Nielsen, 2017; Meyerhoff Nielsen & Krimmer, 2015), increase transparency (Chauhan et al., 2008; López-López et al., 2018) and facilitate citizen engagement (Mahrer & Krimmer, 2005; Navarra & Cornford, 2003). Defined broadly, e-governance refers to the application of Information and Communication Technologies (ICTs) to transform government operations and interactions with citizens, businesses, and other stakeholders (Heeks, 2008; UNDESA, 2022). At its core, e-governance relies on key elements, such as electronic identification (eID) and trust services, interoperability and data exchange systems, electronic payments, and digital communication platforms. Additionally, essential elements include legal frameworks for accessing and reusing public sector information, data protection, and cybersecurity. Together, these frameworks establish the backbone of any transparent, secure, and resilient digital governance ecosystem.

These main elements are underpinned by legal frameworks that regulate their design, implementation, and operation (González et al., 2016; Papadopoulos & Kanellis, 2012; Veit & Huntgeburth, 2014). The quality of regulations is one of the factors determining the practical implementation of these elements and their functionality in practice (Bannister & Connolly, 2011b; Meyerhoff Nielsen & Jordanoski, 2020). Effective regulatory frameworks not only facilitate the implementation of digital solutions but also foster public trust, which is a critical enabler for e-governance adoption (OECD, 2020d). However, adopting a legal framework does not guarantee automatic results or compliance in practice (Jordanoski & Meyerhoff Nielsen, 2023).

Modern legal frameworks play an essential role in e-governance by enabling effective, secure, and transparent

service delivery while fostering innovation (Hasan et al., 2015). They also guide governments in adapting to emerging technologies through principles such as technological neutrality and flexibility, which are critical in managing rapid advancements and jurisdictional complexities (Gregory, 2002; Tojiev, 2024). Their adaptability ensures that public sector initiatives remain resilient and capable of meeting evolving societal and technological needs (Korvat, 2023; Park et al., 2016).

The objective of this paper is to examine the relationship between the maturity of regulatory frameworks and the quality of e-governance developments. It provides a high-level analysis of regulatory approaches adopted in Belgium, Botswana, Ecuador, Estonia, Jamaica, Kyrgyzstan, Kenya, and Singapore. It evaluates their practical outcomes, such as the rollout of adequate technical infrastructure, institutional systems, or frameworks. This analysis addresses the following research question: *How do the maturity levels of regulatory frameworks correlate with the development of e-governance in different countries?* While many existing studies focus on theoretical models or isolated national cases, this research offers comparative, empirical insights into how regulatory maturity shapes digital governance across diverse contexts.

The paper is structured as follows: the second section reviews the literature on the research subject. The methodology and how the study was conducted is presented in the third section. The study results and discussion are presented in the fourth section, while the conclusions and future work are included in the last section.

2. Literature Review

The Role of Regulatory Frameworks in E-Governance

Regulation plays a crucial role in shaping the development, implementation, and performance of digital government systems in every country (López-López et al., 2018; OECD, 2020b). The design and implementation of e-governance initiatives are directly influenced by existing legal and policy frameworks (Dovhan et al., 2022; Luna-Reyes et al., 2016). These frameworks provide the necessary legal basis for digital government projects (Luna-Reyes et al., 2016), defining the rules for data handling, service delivery, and citizen engagement. However, the absence of a comprehensive legal framework can lead to uncertainty, increased legal risks, and hinder the adoption of new technologies (Cordella & Bonina, 2012; Muliaro Wafula, 2012).

Effective regulation provides legal clarity, fosters trust, and ensures compliance with privacy and data protection requirements (Chatterjee & N.S., 2022; Hasan et al., 2019). For instance, regulatory frameworks for eID emphasise privacy and security, establishing robust requirements to address potential vulnerabilities in data sharing. Additionally, regulatory frameworks support interoperability and cross-border governance. For example, the experiences of Estonia and Singapore demonstrate how mature regulatory environments encourage both innovation and public adoption of digital government services (Lebid, 2021; Shkarlet et al., 2020). On a cross-border level, the European Health Data Space demonstrates how harmonised regulations can facilitate the secure and efficient exchange of patient health data among public agencies across all EU Member States (Schneider et al., 2024).

International standards and frameworks also significantly influence national regulatory approaches, particularly in areas such as web accessibility (Jordanoski & Meyerhoff Nielsen, 2023), data protection and cybersecurity (Ortega et al., 2023). Adopting these standards can foster interoperability among diverse e-governance systems (Wimmer et al., 2018). However, successful implementation depends not only on adoption but on the ability to adapt such standards to local contexts and administrative capacities. Moreover, the effectiveness of these regulations depends heavily on their enforcement mechanisms and institutional alignment, which vary across jurisdictions.

Despite widespread recognition of regulation's enabling role, the literature remains somewhat fragmented regarding comparative, empirical analyses across diverse country contexts. Most studies focus on either highly developed digital economies or normative frameworks, leaving a gap in understanding how regulation functions in practice across different governance environments.

Technological Advancements and Regulatory Challenges

Technological advancements often outpace regulatory development, creating significant challenges for governments (Dovhan et al., 2022; Luna-Reyes et al., 2016). One prominent challenge is integrating emerging technologies, such as AI and blockchain, within existing legal frameworks without causing fragmentation or inefficiency (Firdaus et al., 2024). Ensuring data privacy with rapid advancements in data analytics and AI remains a pressing issue (Mustafa et al., 2025). While fragmented regulations can undermine public trust and create governance gaps, overly rigid frameworks may hinder innovation. This highlights the need for flexible and adaptive approaches (He, 2011; Nyman-Metcalf, 2014).

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

The federated approach employed in Europe, which emphasises collaborative governance, serves as a potential model for harmonising regulations across regions with diverse legal and infrastructural landscapes (Krimmer et al., 2021). To remain relevant, regulations should be periodically reviewed and updated through stakeholder collaboration. For example, adaptive regulatory practices have been integral to digital transformation efforts in Estonia and Brazil (Franco, 2024; Okon, 2024). Maintaining a balance between innovation and regulation remains critical to avoiding both regulatory delays and stifling innovation (OECD, 2020b; Ortega et al., 2023). In this context, regulatory maturity should be viewed not only as a function of legal completeness or technical scope but also as a reflection of institutional adaptability and alignment with broader governance models. Legal systems must evolve parallel to complex digital infrastructures, requiring coordinated policy responses and long-term strategic planning.

This review provides the conceptual grounding for the study's core objective: to assess how the maturity of regulatory frameworks correlates with e-governance development across different country contexts. While previous literature has established the foundational importance of regulation, empirical studies examining its operational effectiveness through comparative, multi-country case analysis remain limited. This paper aims to address that gap through a structured, cross-country comparative analysis.

3. Methodology

A classical exploratory, qualitative, comparative case study methodology is applied to address the research gaps related to shaping e-governance through regulatory frameworks (Rohlfing, 2012; Yin, 2017). The approach is needed to understand the complex correlation between regulations and e-governance implementation. By analysing the regulatory practices of eight countries, this study aims to understand how regulations contribute to the development and implementation of e-governance. The research uses a theory-informed, evidence-driven comparative approach to identify patterns across cases while remaining attuned to local contexts (Thornberg, 2012).

Case selection

The study includes eight countries (in alphabetical order: Belgium (BE), Botswana (BW), Ecuador (EC), Estonia (EE), Jamaica (JM), Kenya (KE), Kyrgyzstan (KG), and Singapore (SG)) selected based on a combination of geographic, economic, and cultural diversity and varying degrees of e-governance maturity. The diversity of these cases ensures that the findings reflect a broad spectrum of regulatory capacities and implementation realities rather than being limited to high-income or digitally advanced economies. Case selection also considered the availability of documented legal frameworks, policy materials, and national e-governance initiatives. Table 1 presents the contextual factors, i.e. the key socioeconomic and connectivity indicators for the eight countries to support the comparative analysis that may shape digital governance capacity.

Tab. 1 – Socioeconomic (a-e) (CIA.gov, 2025) and connectivity indicators (f-i) (ITU, 2025).

Indicator	BE	BW	EC	EE	JM	KE	KG	SG
a) Population (millions, 2024 est.)	11.9	2.4	18.3	1,2	2.8	58,2	6.1	6.0
b) Territory (thousands, km^2)	30.5	581.7	283.5	45.2	10.9	580.3	199.9	719.0
c) Urbanisation (%) of total population (2023)	98.2	72.9	64.8	69.8	57.4	29.5	37.8	100
d) GDP (PPP) (billions, USD, 2023 est.)	756.6	46.7	260.2	58.2	29.2	314.5	45.5	754.7
e) GDP per capita (PPP) (thousands, USD, 2023 est.)	64.2	18.8	14.5	42.5	10.3	5.7	6.4	127.5
f) Individuals using the Internet (%)	94	77.3	69.7	91	82.4	40.8	79.8	96
g) Households with Internet access at home (%)	94.4	78.3	60.4	95	75.4	50.2	93.4	98.7
h) Active mobile broadband subscriptions per 100 inhabitants	94.9	108	59.4	210	66.7	59	175	164
i) Population covered by at least a 4G/LTE mobile network (%)	100	91	93.9	99	99	97	96.9	100

The socioeconomic profiles of the eight countries reveal significant disparities. High-income countries such as Singapore and Belgium operate in vastly different resource environments than lower-income peers like Kenya or Kyrgyzstan. These economic conditions directly influence the capacity of the governments to invest in national

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

digital infrastructure and establish robust regulatory oversight bodies, factors repeatedly shown to affect e-governance development. Population size and territorial spread also introduce implementation asymmetries. For instance, Kenya and Botswana have large geographic areas and highly rural populations, making connectivity rollouts and last-mile digital service delivery more logistically and financially demanding. In contrast, Singapore's dense urban environment and compact geography offer inherent efficiencies for digital service scaling.

Finally, while digital infrastructure is not the central focus of this study, it is a key enabling condition that shapes the operational feasibility of e-governance systems. In that regard, several countries demonstrate high levels of internet penetration, household connectivity, and mobile broadband subscriptions, indicating well-established digital infrastructure. These conditions suggest a strong baseline for the delivery and adoption of online government services. In other contexts, infrastructure access remains uneven. Lower household internet access rates, modest broadband subscription levels, and digital divides between urban and rural populations signal potential barriers to inclusive digital service deployment. While mobile network coverage is broadly high, approaching universal 4G availability in most countries, this does not automatically translate into effective usage.

Together, these structural factors help explain why legal reforms alone may not suffice, particularly in low- and middle-income countries. Instead, regulatory ambition must be accompanied by targeted policies that account for economic, geographic, and demographic constraints, ensuring that digital transformation strategies are realistic and inclusive.

Data Sources and Analytical Framework

The primary and secondary sources included official legislative texts, policy documents, official reports, and academic literature. The objective was to identify the common principles, discrepancies, and patterns across the selected jurisdictions. For that purpose, the study employed a cross-case comparative analysis, which enabled the evaluation of the common principles while considering the unique factors that influence regulatory effectiveness in each country.

The analysis focuses solely on legal frameworks that are applicable and went into effect before October 1st, 2024, and regulate fundamental e-governance elements, such as eID, trust services, interoperability, access to and reuse of public sector information, electronic payments, digital communications, data protection, and cybersecurity. The study excludes national procedural legislation governing administrative and judicial processes. It also omits the sectoral legislation governing service delivery across various sectors, such as health, education, social protection, and many others. These regulations, although significant, are excluded because each country has developed its unique service delivery ecosystem.

Due to the absence of globally comparable and methodologically consistent data on citizen uptake of government digital services, particularly outside of the European Union (EU) and the Organisation for Economic Co-operation and Development (OECD), this study adopts a basket of internationally recognised indices to serve as proxies for digital governance performance. These indices collectively capture the availability, quality, and usage of core e-governance systems, offering a multidimensional perspective to triangulate regulatory maturity. Specifically, the E-Government Development Index (EGDI), Digital Identity Readiness Index, Online Service Index (OSI), E-Participation Index (EPI), Open Government Data Index (OGDI), and Global Cybersecurity Index (GCI) were selected because of their relevance and cross-country comparability. Each index captures a key dimension of digital governance: the OSI assesses the availability and usability of online public services; the EPI reflects citizen engagement through digital platforms; the OGDI measures open data transparency; the Digital Identity Readiness Index evaluates the sophistication of national eID systems; and the GCI scores cybersecurity frameworks and institutional capacity. Together, these indicators provide a robust empirical foundation for assessing the real-world implementation and institutional effectiveness of digital governance frameworks.

However, the scope and methodology are not without limitations. The findings are context-specific and may not be universally applicable to all countries. Additionally, the study focuses primarily on regulatory frameworks adopted or applicable on the national level. This approach may not fully capture variations in federal or decentralised governance systems (e.g., Belgium). Nevertheless, the chosen methodology provides a strong foundation for examining the legal frameworks that provide valuable insights from good examples or legislative principles that can enhance the quality of the regulations.

4. Findings and Discussion

This section presents the main findings of the study and explores how the maturity of regulatory frameworks influences the development and implementation of e-governance across the eight countries. The analysis is structured around a three-tier maturity classification: advanced, moderate, and early-stage and is based on the scope of legal frameworks, the operationalisation of key digital enablers, and the degree of public service integration and citizen uptake.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

4.1 Maturity Classification

To assess how the depth and operationalisation of legal frameworks influence e-governance performance, this study classifies the eight selected countries into three regulatory maturity categories: advanced, moderate, and early-stage. It is based not on international indices but on a triangulation of legal, institutional, and infrastructural indicators linked to implementing core e-governance components.

Table 2 highlights the classification framework assessing the maturity of regulatory frameworks in e-governance, which is based on three key criteria: (1) *the adoption and scope of legal frameworks*, (2) *the presence and operationalisation of core technical enablers (such as eID, digital signatures, payment systems, notification gateways, and data exchange infrastructure)*, and (3) *the degree of integration and uptake of the online public services*. This classification provided a basis for organising the countries into advanced, moderate, and early-stage maturity groups.

Tab. 2 - Classification criteria for the maturity of regulatory frameworks in e-governance.

Criterion	Advanced	Moderate	Early stage
Regulatory coverage	Comprehensive, up-to-date laws across all key e-governance areas.	Legal instruments adopted for most areas, with some coverage gaps or outdated laws.	Fragmented or partial legal frameworks; significant coverage gaps.
Implementation of key enablers	Fully deployed infrastructure (eID, interoperability, digital services, etc.).	Infrastructure partially rolled out; adoption inconsistent across sectors.	Systems not yet implemented, remain at planning or pilot stages.
Integration and uptake	High levels of citizen engagement, interagency integration, and service use.	Moderate engagement or integration; infrastructure not yet fully utilised.	Low uptake, limited service availability, or minimal system integration.

Based on these criteria, the countries were assessed using evidence from legal documents, institutional arrangements, and available implementation data. This initial classification reflects the degree to which each country's legal frameworks are both comprehensive and operationalised through technical systems and service integration. Belgium, Estonia, and Singapore are classified as having advanced maturity, having adopted comprehensive digital governance frameworks, implemented key enablers, and achieved broad institutional and citizen uptake. Ecuador and Kyrgyzstan fall under the moderate maturity category, having enacted most foundational legal instruments and initiated infrastructure development but still facing gaps in implementation or adoption. Finally, Botswana, Jamaica, and Kenya are considered to be in the early stages of maturity, where legal development remains partial or fragmented, and institutional or infrastructural limitations constrain the operationalisation of technical systems. This classification provides the foundation for the comparative analysis in the sections that follow.

4.2 Regulatory Maturity and Enablers Across Country Contexts

By using the three-tier maturity classification and combining the assessment of the legal-regulatory landscape with the operationalisation of digital enablers, the analysis reveals how regulatory maturity manifests in practice across diverse governance contexts. A comparative summary of key digital enablers is provided in Figure 1, while the e-governance regulatory blueprint of all eight countries is included in the Appendix.

Advanced Maturity Contexts: Belgium, Estonia, and Singapore

The three countries classified as having advanced regulatory maturity have enacted comprehensive and coherent legal frameworks across all major pillars of digital governance. These countries illustrate distinct pathways to achieving regulatory maturity: Belgium through federated coordination within an EU-aligned legal framework, Estonia through legal minimalism paired with deep digital integration, and Singapore through centralised, forward-looking regulatory instrumentation.

Belgium has developed a robust and technically advanced legal ecosystem covering eID, trust services, open data, interoperability, cybersecurity, and data protection. As an EU member state, it aligns closely with supranational frameworks such as the eIDAS and General Data Protection Regulation (GDPR). The country's interoperability infrastructure is institutionalised through shared services managed by the Federal Public Service for Policy and Support (BOSA), which coordinates federal and regional implementation. Belgium's national eID is widely adopted and supports authentication, signatures, and secure access across public and private platforms (OECD, 2020c). However, despite its strong legal and technical foundation, Belgium faces persistent horizontal and vertical coordination challenges due to its complex federal structure. While interoperability frameworks are in place, implementation remains uneven across regions, and harmonisation continues to evolve (OECD, 2020c).

Estonia, also and EU member state, represents a highly integrated and centralised digital governance model rooted in a minimalist but enforceable legal framework. Laws such as the Public Information Act, the Cybersecurity Act, and the Digital Signature Act support core national enablers, including eID and the X-Road data exchange platform. These systems enable secure, real-time data sharing among more than 1,000 public and private organisations (Kotka et al., 2016; Krimmer et al., 2021). The legal infrastructure is tightly coupled with Estonia's technological architecture, ensuring flexibility and rapid legislative responsiveness. Over 99% of public services are available online, and citizen uptake is among the highest in the EU (e-Estonia, 2025). Estonia's ability to translate regulatory ambition into operational infrastructure illustrates the value of streamlined legislation that is fully embedded in the digital delivery ecosystem.

Finally, Singapore exemplifies a centralised and anticipatory model of digital governance. Its legal framework spans key areas such as digital identity, cybersecurity, and data governance and is enforced by dedicated agencies like the Cyber Security Agency of Singapore (CSA) and the Personal Data Protection Commission (PDPC). The Singpass system, used by over 4.5 million residents, provides secure, biometric-enabled access to more than 2,000 services across government and private sectors (GovTech Singapore, 2023). Underpinning this architecture are the Government Data Architecture and the Whole-of-Government Application Analytics (WOGAA), which enable interoperable data flows, predictive service delivery, and policy coherence (Smart Nation and Digital Government Office Singapore, 2024). Singapore's Electronic Transactions Act and Cybersecurity Act embody a forward-looking legal orientation that balances innovation with robust enforcement.

Across all three cases, there is a high degree of alignment between legal frameworks, institutional mandates, and technical implementation. These countries score consistently high in international indices such as the EGDI and the OECD's Digital Government Index (OECD, 2020a; UNDESA, 2024). Their experiences demonstrate that regulatory maturity can serve as a key enabler of digital government performance at scale when legal mandates are embedded within strategic governance models and backed by institutional capacity and long-term investment.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

These models also highlight the importance of integrating legal clarity with user-centric design, security, and cross-sector coordination.

Moderate Maturity Contexts: Ecuador and Kyrgyzstan

Ecuador and Kyrgyzstan represent countries with moderate regulatory maturity. Both countries have enacted legislation in core areas such as digital identity, data protection, and interoperability and introduced national systems to support digital transformation. However, their regulatory ambition is not yet matched by systemic institutional or technical readiness since both countries face persistent implementation, coordination, and public uptake challenges.

Ecuador has adopted a legal ecosystem that includes legislation on electronic transactions, digital signatures, data protection, and access to public information. These frameworks were largely formalised between 2010 and 2020 and have recently been extended to include provisions for interoperability and digital services. Oversight is provided by institutions such as the Telecommunications Regulation and Control Agency (ARCOTEL) and the Ministry of Telecommunications and the Information Society. Ecuador's technical efforts include the development of a Mobile ID system and a national digital signature platform. However, the practical integration of these enablers into service delivery remains limited. Ministries often operate in silos, with weak horizontal coordination and inconsistent enforcement of legal mandates (Apolo et al., 2020; OECD, 2023).

Ecuador's open data policy, while legally established, also suffers from uneven implementation. Some open government data portals are outdated or non-functional, and usage remains low due to gaps in awareness and infrastructure (World Bank, 2021). Similarly, while digital identity is legally recognised, its application across public services is minimal. These issues are combined by technical fragmentation and digital literacy barriers, especially among underserved populations.

Kyrgyzstan, in contrast, has approached digital governance as part of a broader administrative reform agenda. The country has adopted legal frameworks in digital identity, interoperability, cybersecurity, and data protection. One of its most ambitious initiatives is the Tunduk interoperability platform, which enables data exchange across state agencies and provides a technical backbone for integrated digital services. Tunduk has been internationally recognised as a promising digital enabler (e-Governance Academy, 2021), and some ministries have begun integrating it into their service architecture.

However, the operationalisation of Tunduk remains uneven. While legal structures are in place, enforcement mechanisms are weak, and integration is limited in scope. Regional disparities in institutional capacity and infrastructure continue to hamper consistent service delivery, particularly outside of urban centres (UNDP, 2021). In addition, digital literacy remains a barrier to uptake among citizens, limiting the effectiveness of otherwise functional platforms.

Together, Ecuador and Kyrgyzstan exemplify two distinct but overlapping trajectories within the moderate maturity of digital transformation. Ecuador demonstrates the risks of regulatory advancement without institutional follow-through, while Kyrgyzstan shows how infrastructure can outpace legal enforcement and citizen adoption. Both cases highlight the necessity of aligning legal frameworks with operational readiness, institutional coherence, and public engagement to convert digital ambition into sustainable governance outcomes.

Early-Stage Maturity Contexts: Botswana, Jamaica, and Kenya

Botswana, Jamaica, and Kenya represent countries in the early stages of regulatory maturity, where foundational digital reforms are underway but remain fragmented or underdeveloped. While all three have demonstrated political will and initiated national strategies for digital transformation, their legal frameworks often lack coherence, and operational enablers are either nascent or inconsistently implemented. These countries reflect distinct entry points into digital governance: Botswana through cautious regulatory rollout, Jamaica through identification-led reform, and Kenya through platform-driven service expansion without fully consolidated legislation.

Botswana has focused on incremental digital reforms, adopting key legislation such as data protection laws and developing strategic frameworks like the National ICT Policy (Maitlamo). However, critical legal instruments covering digital identity, trust services, interoperability, and secure digital communication are either missing or remain in preliminary stages. The SmartBots initiative has aimed to digitise selected public services, but institutional fragmentation and limited central oversight have slowed broader implementation (Government of Botswana, 2021; UNECA, 2023). Digital ID systems are still in pilot phases, and inter-agency coordination is weak. Open data practices are emerging but suffer from low levels of proactive disclosure and limited availability in machine-readable formats (Ndlovu, 2024). Botswana illustrates a legal and institutional environment that is evolving but lacks the depth and cohesion required for integrated digital governance.

Jamaica has taken a more targeted legislative approach centred on its Data Protection Act (2020) and the phased rollout of the National Identification System (NIDS). These initiatives form the backbone of Jamaica's legal architecture for digital governance, aiming to support secure, identity-based service delivery. However, enabling frameworks for interoperability, trust services, and digital signatures remain underdeveloped or unimplemented. The 2019 Supreme Court ruling, which declared the original NIDS legislation unconstitutional due to privacy concerns, highlighted public mistrust and the need for more robust legal safeguards (Caribbean Policy Research Institute (CAPRI), 2020). Although institutions like the Office of the Information Commissioner exist, they often operate with evolving mandates and limited capacity. Open data initiatives remain sporadic, with most public data either unpublished or not structured for reuse. Jamaica's experience underscores the importance of aligning legal reform with institutional capability and sustained public engagement to build trust and support uptake.

Lastly, Kenya presents a more complex but equally instructive case. The country has launched eCitizen, a major digital portal offering over 5,000 public services, and enacted the Data Protection Act (2019), positioning itself as a regional leader in service digitisation. However, its regulatory framework remains fragmented, with overlapping mandates across agencies and laws covering interoperability, trust services, and digital signatures (CIPESA, 2022; Nyangena et al., 2021). Efforts to introduce national digital ID systems, including Huduma Namba and the more recent Maisha Namba, have faced legal setbacks and public criticism over data protection and exclusion risks. Huduma Namba was suspended by the High Court in 2021 due to inadequate legislative safeguards (Njoya, 2023), and Maisha Namba has encountered similar pushback over insufficient consultation and transparency (Kennedy, 2025). Despite rapid service digitisation, Kenya's experience illustrates that platform expansion without legal and institutional consolidation can undermine public trust and impede sustainable progress.

Taken together, these cases highlight the vulnerabilities of early-stage digital governance contexts. While political support for digital reform exists, legal gaps, institutional fragmentation, and low levels of citizen trust hinder the full operationalisation of enablers. Early-stage countries risk uneven progress and increase the digital divide gap without targeted investment in comprehensive legal frameworks, coordinated governance structures, and public trust-building measures. These findings reinforce the importance of treating regulatory maturity not only as a legislative exercise but as a multidimensional condition grounded in institutional readiness, operational infrastructure, and societal inclusion.

4.3 Cross-Cutting Patterns and Performance Validation

This section synthesises key insights from the previous country analyses by examining how regulatory maturity correlates with broader digital governance outcomes. It shifts from country-level narratives to a more aggregated, cross-case perspective using internationally recognised indicators and longitudinal data. The aim is to empirically validate the maturity classification and identify common drivers and limitations of successful digital transformation.

Empirical Validation through Global Indices

To complement the maturity framework and deepen comparative insights, this section draws on five internationally recognised indices: the Digital Identity Readiness Index, OSI, EPI, OGDI, and the GCI. These indicators capture the operational capacity of digital systems across dimensions such as infrastructure, service availability, citizen engagement, data openness, and cybersecurity. Table 3 summarises country scores across these dimensions.

Tab. 3 – Relevant indicators (Global Digital Identity Index, 2024; ITU, 2024; UNDESA, 2024).

Indicator	BE	BW	EC	EE	JM	KE	KG	SG
Digital Identity Readiness Index	84	54.85	58.02	77.5	33.95	50.43	78.11	81.5
Online Service Index	0.72	0.40	0.89	0.99	0.57	0.78	0.60	0.98
E-Participation Index	0.50	0.27	0.88	0.96	0.44	0.52	0.47	0.96
Open Government Data Index	0.85	0.46	0.85	1.00	0.56	0.59	0.54	1.00
Global Cybersecurity Index	96.81	78.60	87,18	96,04	58.20	98.59	65.59	99.86

The indicators generally reinforce the maturity groupings outlined in Section 4.2. Advanced countries, Belgium, Estonia, and Singapore consistently score high across all categories. Estonia and Singapore are especially strong in service integration and digital ID, while Belgium performs well on open data and cybersecurity. These results illustrate that institutionalised legal frameworks when paired with operational infrastructure, predict stronger e-governance performance. On the other hand, moderate countries, such as Ecuador and Kyrgyzstan, display more uneven profiles. Ecuador performs relatively well in online services and open data, reflecting its emphasis on front-end platforms but scores lower in cybersecurity and institutional coherence. Kyrgyzstan performs comparatively better in digital ID, partly due to the Tunduk platform, but lags in service integration and infrastructure. Finally,

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

early-stage countries, Botswana, Jamaica, and Kenya, generally score lower across most indices. Kenya stands out slightly with a higher GCI score, indicating relative strength in cybersecurity institutions, but remains behind in legal coherence and service integration. These patterns reinforce the broader argument that while legislative reform is a necessary condition, it is insufficient without robust institutions, systems, and citizen trust.

Longitudinal Trends in the EGDI

In addition to cross-sectional comparisons, the E-Government Development Index (EGDI) provides a longitudinal view of each country's trajectory between 2014 and 2024 (Figure 2).

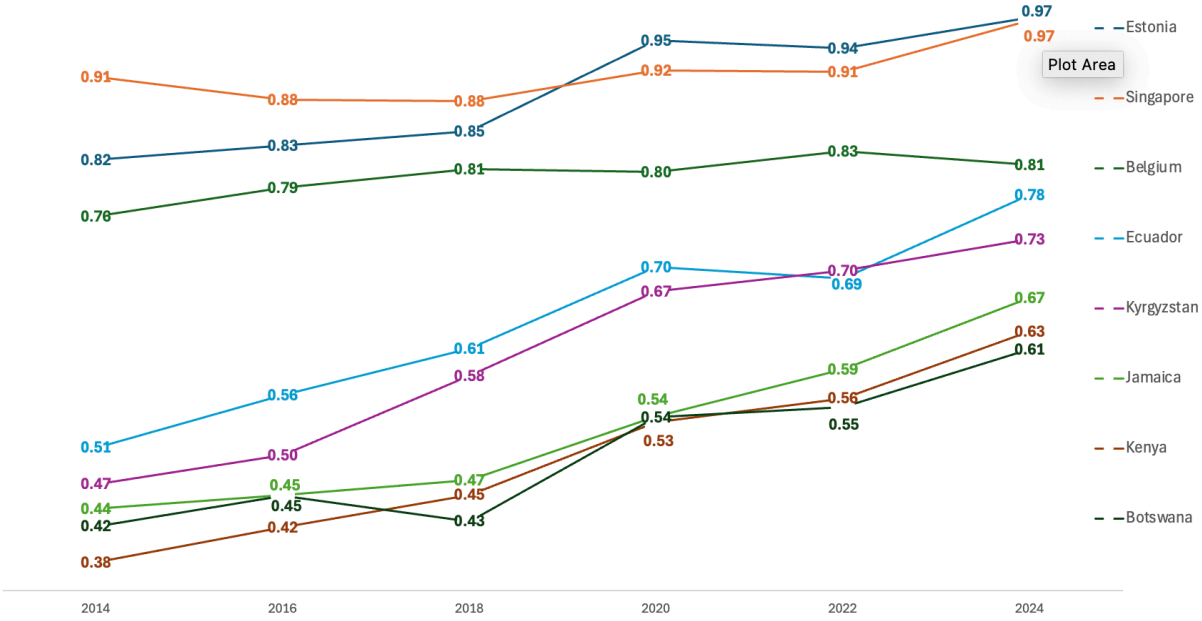

Fig. 2 – E-Government Development Index 2014-2024 (UNDESA, 2025).

Evidently, Estonia and Singapore show sustained progress, with Estonia increasing from 0.85 to 0.97 and Singapore maintaining consistently high scores. These gains are tied to iterative legal updates and investments in whole-of-government architectures. Moderate countries, such as Ecuador and Kyrgyzstan, have demonstrated steady improvement. Ecuador increased from 0.51 to 0.78, supported by platform expansion and external technical assistance. Kyrgyzstan rose from 0.47 to 0.73, reflecting the impact of institutional innovation, policy borrowing, and the rollout of Tunduk.

In contrast, early-stage countries show slower or inconsistent gains. Kenya improved from 0.38 to 0.63 due to its expanding service platforms, but progress is constrained by institutional fragmentation. Botswana and Jamaica exhibit only marginal growth, illustrating the limitations of uncoordinated or under-resourced reform. Interestingly, while classified as advanced, Belgium shows only modest growth (0.76 to 0.81), suggesting that decentralised governance may impede long-term progress despite early regulatory leadership.

Key Cross-Cutting Patterns

Three overarching insights emerge from the cross-country synthesis:

- **Legal frameworks are foundational but insufficient without institutional suppor**t: Advanced countries show that comprehensive legal frameworks embedded in operational systems, such as Estonia's X-Road and eID, enable secure data flows and cross-sector integration (Kotka et al., 2016; Krimmer et al., 2021). However, moderate countries like Ecuador and Kyrgyzstan reveal that legal adoption without enforcement, capacity, and uptake delivers limited outcomes (Bannister & Connolly, 2011b; OECD, 2023). This confirms existing research suggesting that the mere existence of laws does not guarantee compliance or transformation unless supported by enforcement mechanisms and institutional readiness (Bannister & Connolly, 2011b; Jordanoski & Meyerhoff Nielsen, 2023).

- **Institutional capacity and infrastructure determine the impact of regulation**: The implementation gap is widest in moderate and early-stage contexts. Ecuador's legal basis for interoperability is undermined by fragmented governance (Apolo et al., 2020), while Kyrgyzstan's infrastructure investments remain underutilised (UNDP, 2021). By contrast, advanced countries pair regulation with

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

long-term investments in technical and organisational infrastructure (Heeks, 2008). This supports the argument that regulatory maturity must be paired with governance capacity and adequate financing to deliver meaningful digital outcomes (OECD, 2020b).

- **Regulatory maturity is closely linked to interoperability and service integration**: Countries with legal mandates for data exchange and authentication, like Estonia and Belgium, show high levels of integration and service coherence (Bruijn, 2021; Kotka et al., 2016). These frameworks are embedded into public administration, enabling seamless, cross-agency services. In early-stage contexts, the absence of such frameworks leads to siloed systems and duplicative service delivery, limiting scalability and trust (Dovhan et al., 2022; Wimmer et al., 2018).

These findings confirm that regulatory maturity is a strong predictor of e-governance performance but not a guarantee. Countries with established legal frameworks and well-embedded digital enablers consistently outperform those where reform remains fragmented or under-resourced. This cross-cutting synthesis reinforces the value of legal-regulatory maturity as a diagnostic lens while highlighting the risks of symbolic compliance in contexts where enforcement and technical infrastructure are lacking.

4.4 From Regulation to Realisation: Barriers to Effective Implementation

While regulatory maturity is a critical enabler of digital governance, it does not, on its own, guarantee meaningful implementation. Across the eight countries studied, several cross-cutting constraints continue to obstruct the translation of legal frameworks into operational digital ecosystems. These barriers underscore the need for a holistic approach that aligns legal ambition with institutional capacity, infrastructure readiness, and societal inclusion. These include:

- **Legal and Institutional Misalignment:** One of the most persistent challenges is fragmented governance and siloed legal mandates. In countries such as Kenya and Botswana, overlapping responsibilities and weak inter-ministerial coordination have delayed the adoption of shared platforms and hindered the enforcement of national digital strategies. Ecuador faces similar issues, where the lack of vertical alignment between national and subnational regulations has resulted in duplicative efforts and inefficiencies. These patterns reflect broader structural weaknesses, where legal reforms are not sufficiently supported by inter-agency collaboration or clearly defined institutional mandates (Nyman-Metcalf, 2014; OECD, 2020a).

- **Operational and Infrastructure Gaps:** Digital transformation also hinges on robust infrastructure and sustainable investment. In many early-stage countries, inadequate digital infrastructure, such as limited connectivity, fragmented identity systems, or insecure data hosting environments, impairs the rollout of legally mandated systems. Botswana and Kenya exemplify this dynamic, where the technical infrastructure lags behind strategic plans. Even where policies are well-articulated, their implementation is often delayed due to fiscal constraints or reliance on donor funding. Without adequate financing and a long-term maintenance strategy, legal frameworks risk becoming aspirational rather than actionable (OECD, 2020b).

- **Societal Readiness and Trust:** Even the most coherent legal and technical systems depend on societal trust and digital literacy to gain traction. In Jamaica, for instance, the National Identification System (NIDS), though legally established, has faced significant public opposition due to privacy concerns and insufficient consultation. (Caribbean Policy Research Institute (CAPRI), 2020) Similarly, Kenya's Huduma Namba and Maisha Namba initiatives were suspended or contested on legal grounds, with civil society raising concerns over exclusion risks and inadequate data safeguards (Kennedy, 2025; Njoya, 2023). These examples underscore that institutional design must be coupled with public engagement and transparent governance. Without these elements, uptake remains low, and compliance is limited even in legally sound systems (Grigorescu et al., 2016; Sanjay Jadhav, 2023).

Finally, across all maturity levels, governments face growing difficulties in responding to rapid technological change. While Singapore has begun adapting its legal frameworks to accommodate emerging technologies such as AI and fintech, most countries remain reactive, contributing to regulatory lag and oversight gaps (Firdaus et al., 2024; OECD, 2020b). This mismatch between innovation cycles and legislative evolution highlights the need for more agile, anticipatory regulatory design.

5. Conclusion and Future Work

This paper examined how the maturity of regulatory frameworks correlates with the development of e-governance across a diverse set of countries. While regulatory frameworks are indispensable for enabling secure, efficient, and resilient digital government systems, their effectiveness depends on broader structural and institutional

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

conditions. The findings confirm that legal design alone is insufficient unless matched by operational capacity, coordinated governance, and public engagement. As digital transformation accelerates globally, the ability of governments to align legal innovation with institutional capacity and societal needs will remain a decisive factor in shaping the future of digital public administration.

Drawing from a cross-case comparative analysis of eight jurisdictions, the findings confirm that comprehensive, coherent, and enforceable regulatory environments are closely associated with more advanced e-governance outcomes. Countries with mature legal systems, such as Belgium, Estonia, and Singapore, have successfully implemented key digital enablers, achieved high levels of interoperability, and fostered institutional and citizen trust in digital services. This conclusion is further supported by comparative analysis using internationally recognised indicators, which offer empirical validation of the observed regulatory maturity classifications. In contrast, jurisdictions with fragmented or underdeveloped regulatory frameworks face persistent challenges related to implementation, enforcement, and scalability. These barriers, ranging from legal fragmentation to enforcement gaps and infrastructure constraints, demonstrate the need for regulatory maturity to be understood as both a legal and operational condition.

This research introduces an empirically grounded, three-tier classification of regulatory maturity (advanced, moderate, and early-stage) based on legal scope, system operationalisation, and institutional integration. By combining qualitative analysis with internationally recognised indicators (e.g., EGDI, OSI, EPI, GCI), the study offers a replicable framework for diagnosing regulatory readiness across diverse national contexts. It also serves as a practical benchmarking tool for policymakers, enabling the identification of regulatory gaps and supporting targeted reforms aligned with national capabilities and digital ambitions.

Future research could extend this analysis by examining the influence of global and regional legal frameworks, such as the EU's eIDAS, GDPR, and NIS2, the OECD's digital governance principles, or emerging global standards on Artificial Intelligence, in shaping domestic regulatory ecosystems. Also, further work could examine the effects of regulatory design at subnational or federal levels, particularly in countries with decentralised governance structures, such as Belgium, Australia, or India. Longitudinal studies could also help clarify how legal frameworks adapt to technological change and whether regulatory evolution leads to sustained governance outcomes. Understanding how legal frameworks evolve over time and how they respond to emerging technologies will be essential for designing future-ready digital governance systems.

Track 14: Organizational Factors, Adoption Issues, and Value Creation of Digital Government

Track Description

The adoption and implementation of new ICTs by public organizations have been influenced by organizational factors such as resource availability (i.e., funding, infrastructure, technological knowledge, and personnel), leadership, trust, stakeholder involvement, organizational structure and culture, as well as inter-organizational dynamics. Similarly, the adoption of ICTs in government and society has had significant impacts on the organizational processes, effectiveness, and innovativeness of public organizations, as well as on the new governance structure of government and societal impacts. This track aimed to gather research that examines the organizational factors that influence the adoption and implementation, and investigates the impacts, especially the value creation, of new and emerging innovative technologies such as smart city, artificial intelligence, data analytics, big data, open data, social media, citizen-centric technologies, and other novel technologies, as well as theories and practices of adopting innovative policies and practices to facilitate the strategic use of various ICTs by public organizations.

Submitted: 31 January 2025, Revised: 26 March 2025, Accepted: 21 April 2025, Published: 21 May 2025

Abstract. The increasing complexity of the extensive regulatory frameworks in the European Union (EU) creates significant challenges for public procurement processes. Besides the existing Public Procurement Directives, new regulations, such as the Corporate Sustainability Reporting Directive (CSRD), the Corporate Supply Chain Due Diligence Directive (CSDDD), and the EU Taxonomy Regulation introduce intricate compliance requirements that strain existing procurement standards and systems. This paper explores the pivotal role of Governance, Risk, and Compliance (GRC) frameworks as enablers of legal interoperability and process optimization in this evolving landscape. The research first develops an overview matrix categorizing EU regulations from 2021 to 2027 based on their relevance and impact on public procurement. Building on this foundation, a second matrix maps tailored solution components to core challenges posed by high impact regulations, identifying critical areas requiring intervention. Synthesizing these findings, the paper proposes enhancements to current standards for electronic public procurement. These include extending the European Single Procurement Document (ESPD), introducing standalone reporting formats, and leveraging GRC software to manage compliance complexities. The study highlights the importance of integrating GRC frameworks with scalable, AI-driven solutions to foster legal interoperability and operational resilience. It therewith offers actionable insights for policymakers, for practitioners in the public procurement processes, and for researchers.

Keywords. Regulation, GRC, Interoperability

Research paper, DOI: https://doi.org/10.59490/dgo.2025.978

1. Introduction

Governance, Risk, and Compliance (GRC) are increasingly important for managing organizational frameworks, optimizing business processes, and ensuring adherence to a rapidly evolving regulatory landscape (Racz, Weippl, Seufert, et al., 2010). In an era shaped by resource scarcity, stringent environmental requirements, and demographic transformations, effective governance has emerged as a cornerstone for leveraging available resources efficiently while mitigating risks through compliance with clear and enforced regulations (Racz, Weippl, & Seufert, 2010). These principles are particularly significant within the European Union (EU), where the regulatory environment is becoming increasingly complex (Knill & Liefferink, 2021).

The EU has introduced several large-scale regulations to address pressing societal and environmental concerns. Notably, the Corporate Sustainability Reporting Directive (CSRD) (Directive (EU) 2022/2464 of the European Parliament and of the Council of 14 December 2022 Amending Regulation (EU) No 537/2014, 2022) seeks to enforce comprehensive environmental accountability, while the Supply Chain Due Diligence Act (Directive - EU - 2024/1760 - EN - EUR-Lex, 2024) mandates rigorous governance and transparency across supply chains. Complementary policies targeting carbon emissions, anti-money laundering, human rights protection, and whistleblower safeguards further underscore the criticality of compliance frameworks (Directive - 2019/1937 -

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

EN - Eu Whistleblowing Directive - EUR-Lex, 2019; Latest Update on Anti-Money Laundering and Countering the Financing of Terrorism Legislative Package - European Commission, 2024; Regulation - 2020/852 - EN - Taxonomy Regulation - EUR-Lex, 2020; Regulation - 2022/2554 - EN - DORA - EUR-Lex, 2022; Regulation - 2022/2560 - EN - EUR-Lex, 2022; Regulation - 2023/956 - EN - Cbam Regulation - EUR-Lex, 2023; Regulation - 2024/2847 - EN - EUR-Lex, 2024). Together, these regulatory advancements impose increased obligations on organizations to align their operational models with legal and ethical standards (Ionel Zamfir, 2020).

Public procurement, a sector already navigating an intricate web of legal and procedural requirements, is heavily affected by this regulatory transformation (Mohungoo et al., 2020). The intricate interplay between compliance and operational efficiency presents a dual challenge: meeting the new regulatory demands without compromising the inclusivity and functionality of procurement processes (Sonntagbauer & Bodiroza, 2009). The existing complexities in public procurement often dissuade private actors, particularly small and medium enterprises, from participation, stifling competition and innovation (Di Mauro et al., 2020; Flynn, 2018). To address these challenges, both contracting agencies (CAs) in the public sector and economic operators (EOs) participating in the public procurements must adopt comprehensive GRC frameworks that balance compliance imperatives with procedural efficiency (Vicente & Mira Da Silva, 2011). Multiple challenges on the maintenance of legal interoperability also have to be addressed (European Commission, 2017; Schmitz & Wimmer, 2023). Furthermore, implications of legal frameworks on current and future standards in public procurement need to be taken into account early (Guijarro, 2009).

This paper investigates the growing importance of GRC in public procurement and its potential role as an enabler of interoperability, along with the implications of new and forthcoming EU regulations. It delivers the following key contributions:

1. **Regulation matrix with an overview of new and recent EU regulations:** A structured matrix categorizing key EU regulations from 2021–2027 evaluates their relevance and potential impact on public procurement. By analyzing their regulatory requirements, the matrix highlights focus areas such as sustainability, supply chain due diligence, and carbon footprint assessments in public procurement procedures.

2. **Matrix mapping solution components and recommendations for the adoption of identified regulations:** Using the insights from the regulation matrix, the paper develops a second matrix mapping tailored solution components to core challenges in implementing these regulations. We develop actionable guidance for public administrations and economic operators. And we emphasize the role of GRC systems in achieving compliance and operational efficiency.

3. **Identification of gaps and enhancement potentials in the current standardization landscape:** We synthesize the two matrices and identify critical gaps in existing procurement standards, such as the need for standardized reporting formats and enhanced interoperability mechanisms. We propose enhancements, such as extending the ESPD and creating standards, to address these gaps and ensure regulatory alignment and process optimization.

Through these contributions, we emphasize the pivotal role of GRC as an enabler of regulatory adherence, legal interoperability, and process optimization. By integrating GRC principles with the established frameworks of interoperability, it is possible to mitigate the cascading effects of regulatory changes on procurement processes (Kalusivalingam et al., 2022). The paper aims to guide stakeholders in developing a more resilient and adaptive procurement ecosystem that addresses both compliance requirements and operational efficiency by means of structured GRC management.

The paper is structured as follows: Chapter 2 describes the research design. Chapter 3 elaborates on the theoretical background of related research topics based on academic literature. Chapter 4 presents an overview of relevant regulations, while chapter 5 proposes potential solutions to overcome the challenges of each high-impact regulation. Chapter 6 explores the impact on the standardization landscape. Finally, chapter 7 and 8 provide a discussion, closing thoughts, and future research needs.

2. Methodology and research design

This study employs Design Science Research (DSR) to explore and address the challenges of Governance, Risk, and Compliance (GRC) in public procurement. DSR is particularly suited for this research as it combines theoretical analysis of scientific literature (rigour cycle) and needs from practice (relevancy cycle) with solution development (design cycle) (Hevner & Chatterjee, 2010; Hevner et al., 2004). Three key questions guide this research:

1. **Which recent and upcoming EU regulations are most relevant to public procurement processes?**

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

2. **How can Contracting Authorities (CAs) and Economic Operators (EOs) effectively comply with these regulations while maintaining operational efficiency?**

3. **What are the impacts of these regulations on existing procurement standards, and how can those standards be enhanced to ensure compliance and interoperability?**

We systematically examined these questions through three interlinked research cycles along DSR, which build upon one another to integrate theoretical insights with practical needs. The first research cycle establishes the foundational state of the art by conducting a comprehensive review of academic literature and EU regulatory frameworks based on Webster and Watson (Webster & Watson, 2002). In total, 47 scientific sources and 8 regulatory sources were selected for analysis. We divided them into three categories: theoretical grounding (28 sources), regulation-focused studies (15 sources), and methodological references (2 sources).

The literature review employed a multi-step filtering process to ensure quality and relevance. Theoretical sources, initially numbering 143, were filtered through abstract and conclusion screening, followed by full-text evaluation, resulting in a final selection of 28 sources. Regulation-based studies began with 73 identified documents, which were screened in a similar way, leading to a final set of 15 sources. The search process utilized keywords such as "interoperability," "standardization," "public procurement," and "GRC" across databases including SCOPUS, Web of Science, and ScienceDirect.

In parallel, corresponding to the relevancy cycle in the DSR approach, EU regulations were analyzed through official documentation, legislative drafts, and European Commission policy analyses. Focus was on recent and upcoming regulations with high potential impact on public procurement. Key themes, such as environmental accountability, supply chain transparency, and legal harmonization, were identified and structured into a regulation matrix that categorized and evaluated their relevance.

The authors, with academic expertise in public procurement and regulatory interoperability, synthesized regulatory requirements and scientific findings to develop two practical artifacts: (1) a regulation impact matrix and (2) a solution mapping matrix. These are not merely summaries, but conceptual tools designed to support strategic implementation and compliance decisions in public procurement. The development of these artifacts aligns with the design cycle of Design Science Research and aims to bridge theory with practice by proposing actionable, replicable solutions.

The second research cycle builds on the insights from the regulation matrix by developing a second matrix that maps solution components to the core challenges posed by emerging EU regulations. This matrix serves as a practical artifact, providing actionable guidance for CAs and EOs to adopt the identified regulations effectively. Furthermore, the related legal publications and scientific sources are mapped to the corresponding findings.

The third research cycle synthesizes the findings of the first two matrices to identify critical gaps in existing procurement standards and proposes targeted enhancements. Research cycle two and three are mostly motivated by the design cycle of DSR, taking into account rigorous and relevant findings from the previous research steps.

3. Theoretical Background on Interoperability, GRC and Public Procurement

3.1 Interoperability

Interoperability is fundamental to public procurement, enabling seamless interaction between systems, organizations, and regulations (Gascó, 2012). It encompasses technical, semantic, organizational, and legal dimensions, each contributing to efficient information exchange and compliance (Kalogirou et al., 2020). The European Interoperability Framework (EIF) emphasizes the legal layer as the highest level of interoperability, ensuring regulatory alignment across jurisdictions and profoundly influencing the other three dimensions (European Commission, 2017; Kouroubali & Katehakis, 2019).

The legal layer is particularly critical in public procurement. Public procurement laws and policies are shaping how the procurement process must look like and how actors need to collaborate. Further new harmonized regulations, such as the Corporate Sustainability Reporting Directive (CSRD) and the Supply Chain Due Diligence Act, establish a unified framework for accountability and sustainability (Baumüller & Sopp, 2021; Sönnichsen & Clement, 2020). These gain importance also regarding awarding criteria (Sönnichsen & Clement, 2020). Misaligned regulations can hinder collaboration, creating inefficiencies and increased compliance costs (Guijarro, 2007). The EIF's emphasis on standardized legal instruments addresses these challenges, fostering consistent application across member states. Beyond the legal layer, interoperability depends on organizational, semantic, and technical standards, and on their successful alignment and integration. Organizational processes must align with regulatory requirements,

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

such as standardized evaluation criteria for sustainability (Schmitz et al., 2023). Semantic interoperability must ensure consistent understanding of data through common vocabularies and formats, critical for accurate reporting under directives like the CSRD (Wimmer et al., 2018). Technical interoperability relies on compatible systems and protocols, exemplified by the Peppol framework, which facilitates efficient data exchange in procurement. Interoperability is not static but evolves with regulatory and technological changes (Hellberg & Grönlund, 2013). Therefore, a closer look on interoperability along new regulations and GRC is advisable.

3.2 Governance, Risk, and Compliance (GRC)

Governance, Risk, and Compliance (GRC) has emerged as an essential framework for organizations navigating increasingly complex regulatory environments (Racz, Weippl, & Seufert, 2010). At its core, GRC integrates three interrelated functions: governance, which involves the alignment of organizational strategies and goals (Haugh & Bedi, 2023); risk management, which focuses on identifying, assessing, and mitigating potential threats; and compliance, which ensures adherence to laws, regulations, and internal policies. Together, these functions support in achieving organizational resilience and accountability while optimizing processes and resource allocation (Racz et al., 2010).

Recent research underscores the growing significance of GRC as a driver of regulatory adherence and operational efficiency. The introduction of regulations, such as the Corporate Sustainability Reporting Directive (CSRD) and the Supply Chain Due Diligence Act, further stress the need for robust GRC frameworks (Di Natale & Cordella, 2023). These frameworks are not only tools for compliance but also enablers of strategic decision-making, offering insights into risk exposure and areas requiring optimization. Organizations with integrated GRC systems can proactively manage risks and adapt to changing regulatory landscapes, gaining a competitive advantage (Zamfir, 2020).

Both public and private sectors benefit significantly from effective GRC management. Public administrations leverage GRC frameworks to maintain transparency and accountability while managing limited resources. For example, GRC processes help optimize procurement workflows, ensuring compliance with sustainability criteria and minimizing risks of regulatory breaches. Similarly, EOs utilize GRC systems to streamline reporting obligations, enhance supply chain oversight, and mitigate financial and reputational risks. In times of resource and personnel scarcity, the importance of GRC becomes even more pronounced. Efficient GRC management enables organizations to prioritize critical risks and deploy targeted measures, reducing administrative burdens while maintaining compliance. Optimizing GRC processes fosters greater organizational agility, allowing stakeholders to address emerging challenges effectively (Racz et al., 2010).

3.3 Public Procurement

Public procurement plays a pivotal role in public sector operations, accounting for a significant proportion of government expenditure across the EU (Siapera et al., 2023). As a highly regulated domain, it is directly influenced by legal interoperability, which ensures consistency and alignment of regulations across jurisdictions (Gualdi & Cordella, 2022). The European Interoperability Framework (EIF) identifies the legal layer as a critical enabler for achieving seamless procurement processes, emphasizing the importance of harmonized legal instruments to facilitate cross-border collaboration and compliance (Kalogirou et al., 2020).

The legal layer's impact on public procurement becomes particularly evident in the context of evolving EU regulations. Policies such as the Corporate Sustainability Reporting Directive and the Supply Chain Due Diligence Act introduce new criteria for supplier evaluation, requiring public administrations to integrate sustainability and accountability metrics into procurement decisions. These regulations highlight the dependency of procurement processes on clear and enforceable legal frameworks, which serve to reduce ambiguities and promote transparency (Hummel & Bauernhofer, 2024; Zamfir, 2020).

Academic research underscores the importance of governance, risk, and compliance (GRC) management in addressing the complexities of public procurement (Di Mauro et al., 2020; Okoye et al., 2024). GRC frameworks provide public administrations with the tools to navigate regulatory requirements effectively while optimizing procurement workflows (Racz, Weippl, & Seufert, 2010). By incorporating GRC principles, public administrations can mitigate risks, such as non-compliance or supply chain disruptions, and enhance the overall integrity of procurement processes (Vicente & Da Silva, 2011). The introduction of GRC management in public procurement also offers significant opportunities for improvement. Success factors identified in the literature include the use of standardized evaluation criteria (Qiao & Cummings, 2003; Siapera et al., 2023), enhanced interoperability of data systems (Abraham et al., 2019), and stakeholder collaboration (Ruijer, 2021). Their translation from policies to practice, a common challenge in e-procurement, could benefit from it as well (Hardy & Williams, 2008).

3.4 Synthesis of the interplay between GRC, interoperability and public procurement

The interplay between GRC, interoperability and public procurement demonstrates a cohesive relationship, where each concept reinforces the others. Regulations, as the driving force behind modern public procurement practices, are intricately tied to the legal layer of interoperability. This layer ensures that regulatory frameworks are harmonized across jurisdictions, fostering consistency in procurement standards and processes.

GRC frameworks are pivotal in bridging the gap between regulatory mandates and operational execution. Their integration into procurement practices provides a structured approach to compliance, enabling CAs and EOs to manage risks effectively while adhering to stringent regulations. By embedding GRC processes into the legal interoperability layer, organizations can streamline regulatory implementation, mitigate non-compliance risks, and optimize resources.

The close interconnection between these concepts underscores the necessity of further research and practical advancements in GRC as a supporting mechanism for regulatory implementation. Effective GRC frameworks not only facilitate compliance but also enhance interoperability by ensuring that procurement standards remain aligned with legal requirements and technical capabilities.

4. Evaluation of upcoming EU Regulations relevant to Public Procurement

Section 4 provides a comparative overview of relevant EU-Regulations that are planned or released in the timeframe from 2021-2027. Based on this overview, an evaluation of the regulations in regard to their expected impact on public procurement is conducted. Regulations with an expected high impact on public procurement are further analysed and put into perspective of findings from literature and current procurement procedures.

4.1 Overview of EU-Regulations impacting Public Procurement

In **Tab. 1**, we summarize key EU regulations and directives from 2021 to 2027, we categorize their areas of impact and provide an assessment of the expected impact of each regulation on public procurement. Regulations that exhibit no direct implications for public procurement processes are categorized with low impact. Regulations that necessitate changes in the behaviour of actors involved in public procurement procedures or influence the formal procurement processes are rated with medium impact. Regulations that significantly affect procurement content, standards, or processes—requiring the adoption of new frameworks or substantial adjustments—are rated with high impact.

The selection of the regulations is based on their legal scope, implementation timeline (2021–2027), and direct or indirect influence on public procurement procedures. Relevance was assessed based on whether a regulation introduces new reporting requirements, modifies procurement standards, or alters evaluation criteria for suppliers. While all listed regulations have some level of impact, the three with the most substantial and systemic implications—CSDDD, CSRD (in conjunction with the EU Taxonomy), and CBAM, are explored in greater detail in subsections 4.2 to 4.4. These were chosen because they require significant adaptations to current standards, and these introduce complex reporting and governance demands. Besides conducting a systematic analysis of these regulations, the authors consider themselves knowledgeable in the public procurement regulatory field, as they are collaborating in different research and standardization projects and initiatives at European and national level in Germany for more than a decade. They are members of the German "Cooperation Project on Digital Procurement"[1] funded by the German IT Planning Council, along which this research has evolved. Subsequently, we outline the main aspects of each identified EU regulation impacting public procurement in the EU.

The Regulation (EU) 2022/2560 on foreign subsidies aims to address distortions in the internal market caused by external subsidies. Public procurement processes require greater scrutiny of bids, particularly from non-EU entities, to ensure compliance with anti-subsidy measures. This will enhance fairness in procurement but may also increase administrative burdens in the processes.

The Digital Operational Resilience Act (DORA) introduces stringent cybersecurity standards for financial institutions and service providers. Public procurement will need to include robust cybersecurity criteria in tender specifications for ICT services, potentially raising procurement costs while strengthening system resilience.

Tab. 1 - Overview of recent and upcoming EU regulations impacting public procurement across Europe.

Name/Subject of, number, and reference to regulation	Date of Planning	Date of Implementation	Summary Description of the Regulation	Category	Expected impact on public procurement
Regulation on foreign subsidies distorting the internal market (EU) 2022/2560 (Regulation - 2022/2560 - EN - EUR-Lex, 2022)	2022	December 2022	Addresses foreign subsidies that distort the internal market, ensuring fair competition.	Market Competition	Medium
Digital Operational Resilience Act (DORA) 2022/2554 (Regulation - 2022/2554 - EN - DORA - EUR-Lex, 2022)	2022	January 2025	Enhances digital operational resilience for the financial sector, improving ICT risk management and stronger cybersecurity standards for financial institutions.	Cybersecurity	Medium
Corporate Sustainability Due Diligence Directive (CSDDD) 2024/1760 (Directive - EU - 2024/1760 - EN - EUR-Lex, 2024; LkSG, 2021)	2021	January 2023 (DE), 2026 (EU-wide)	Mandates human rights and environmental due diligence in supply chains, promoting greater accountability in global supply chains; increased compliance requirements.	Sustainability	High
Whistleblower Protection Directive (2019/1937) (Directive - 2019/1937 - EN - Eu Whistleblowing Directive - EUR-Lex, 2019)	2019	2022-2023	Protects whistleblowers reporting breaches of EU law, encouraging transparency and accountability.	Governance	None
Corporate Sustainability Reporting Directive (CSRD) 2022/2464 (Directive (EU) 2022/2464 of the European Parliament and of the Council of 14 December 2022 Amending Regulation (EU) No 537/2014, 2022)	2021	January 2023 (Phased until 2026)	Expands sustainability reporting requirements for companies. Increased transparency in corporate sustainability performance.	Sustainability	High
EU Taxonomy Regulation 2020/852 (Regulation - 2020/852 - EN - Taxonomy Regulation - EUR-Lex, 2020)	2020	2022 (ongoing updates)	Provides a classification system for environmentally sustainable activities. Guides investments toward sustainable activities and supports green transitions.	Sustainability	High
EU Legislative Package on AML/CFT (Latest Update on Anti-Money Laundering and Countering the Financing of Terrorism Legislative Package - European Commission, 2024)	2021	2025-2026	Creates a centralized AML Authority and unifies AML/CFT measures across the EU. Stronger oversight and harmonized rules for combating money laundering and terrorist financing.	Financial Integrity	Medium
Carbon Border Adjustment Mechanism (CBAM) 2023/956 (Regulation - 2023/956 - EN - Cbam Regulation - EUR-Lex, 2023)	2021	October 2023	Introduces carbon pricing for imports to prevent carbon leakage. Encourages adoption of cleaner production methods and aligns global standards with EU policies.	Sustainability	Medium
Cyber Resilience Act 2024/2847 (Regulation - 2024/2847 - EN - EUR-Lex, 2024)	2022	2027	Requires manufacturers to integrate cybersecurity throughout product lifecycles.	Cybersecurity	Medium

The Supply Chain Due Diligence Act (and its EU-wide counterpart under the Corporate Sustainability Due Diligence Directive) requires companies to identify and mitigate human rights and environmental risks in their supply chains. This regulation will reshape public procurement by necessitating strict sustainability and ethical sourcing criteria, particularly for global supply chains. These criteria should be integrated into existing standards or require new standards with a structured format.

The Whistleblower Protection Directive enhances transparency and has no apparent impact on procurement procedures.

The Corporate Sustainability Reporting Directive (CSRD) expands corporate sustainability reporting requirements. This will indirectly influence procurement by encouraging contracting authorities to prioritize suppliers with detailed sustainability disclosures. Managing these report obligations is complex and very data intensive. It therefore needs to be supported by some kind of structured approach.

The EU Taxonomy Regulation provides a classification framework for environmentally sustainable activities, significantly impacting sectors such as construction, energy, and transportation. Public procurement processes need to be aligned with these standards, prioritizing suppliers and projects that support the EU's environmental objectives. An integration into existing procurement standards would be paramount for efficient implementation.

The EU Legislative Package on AML and CFT aims to combat money laundering and terrorist financing by strengthening oversight and harmonizing anti-money laundering measures across member states. Public procurement authorities will need to enhance due diligence processes, incorporating stricter prequalification checks and ongoing monitoring of contracts to mitigate financial crime risks. However this can likely already be achieved by extending some corresponding criteria, that are already part of the ESPD.

The Carbon Border Adjustment Mechanism (CBAM) introduces carbon pricing on imports to prevent carbon leakage. Public procurement will need to incorporate carbon footprint assessments into tender evaluations, especially in high-emission sectors, thereby promoting the use of low-carbon goods and services. Adjusting procurement standards to reflect these assessments in a structured form might be pivotal.

The Cyber Resilience Act mandates cybersecurity measures across the lifecycle of digital products, influencing procurement in technological domains. Contracting authorities must include cybersecurity requirements in contracts for digital goods and services, which could raise costs but will enhance security and resilience.

Finally, the EU Packaging Regulation 2025 promotes sustainable materials and efficient packaging solutions. Public procurement authorities will need to prioritize suppliers adhering to circular economy principles and resource efficiency, aligning with the EU's broader sustainability goals.

Based on the above assessment, the CSDDD, CSRD & EU-Taxonomy, and CBAM will have the highest impact on procurement procedures. These will likely necessitate changes to existing standards or the development of new standards. We, therefore, focus on these high-impact critical regulations in the subsequent subsections 4.2-4.4.

4.2 Corporate Supply Chain Due Diligence Directive (CSCDDD)

Literature has shown that risk management is a critical aspect of global supply chain management, as it addresses the uncertainties and challenges posed by economic policies, globalization, and disasters, which significantly affect organizational financial performance and national economies (Gurtu & Johny, 2021). Effective risk management in international supply chains requires a nuanced understanding of the unique economic, infrastructural, and geopolitical dynamics of each region. Businesses must prioritize tailored strategies that leverage advanced technologies and local collaborations to build resilience and ensure the smooth functioning of supply networks (Okoye et al., 2024). The voluntary approach to corporate social responsibility in supply chains, while initially promising, has proven insufficient to address the systemic issues of human rights violations, environmental degradation, and governance challenges in developing countries. Multinational companies often operate in contexts where weak regulatory frameworks fail to enforce accountability, allowing exploitative practices to persist (Weihrauch et al., 2023).

The Corporate Supply Chain Due Diligence Directive (CSDDD) represents a transformative regulatory measure aimed at fostering accountability and sustainability within global supply chains. Initially introduced in Germany, the CSDDD has influenced broader European Union (EU) initiatives to mandate corporate responsibility for human rights and environmental impacts along their entire supply chains. The regulation requires companies to identify, assess, and mitigate risks associated with human rights violations, child labor, and environmental degradation, emphasizing due diligence obligations that extend beyond direct suppliers to include indirect supply chain actors

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

(*Directive - EU - 2024/1760 - EN - EUR-Lex*, 2024). These combined factors make a structured GRC-Management paramount to cover the requirements set out by the CSDDD.

Moreover, the Act's emphasis on supply chain transparency necessitates enhanced interoperability among procurement systems (Schilling-Vacaflor & Gustafsson, 2024). Public administrations will require standardized tools and data formats to verify supplier compliance, potentially leveraging frameworks such as Peppol to facilitate the exchange of due diligence documentation. Economic operators, on the other hand, must invest in supply chain monitoring technologies and reporting mechanisms to provide verifiable evidence of compliance and risk based compliance systems (Gervais et al., 2023). While the CSDDD enhances accountability and ethical practices, it also introduces challenges, including increased administrative burdens and compliance costs. Smaller suppliers may face particular difficulties in meeting the requirements, potentially limiting their participation in public procurement (Smit et al., 2021). To address these issues, capacity-building initiatives and collaborative approaches between public administrations and private sector actors will be critical.

4.3 Corporate Sustainability Reporting Directive (CSRD) and the EU Taxonomy Regulation

The Corporate Sustainability Reporting Directive (CSRD) and the EU Taxonomy Regulation collectively represent a significant shift in how organizations disclose and evaluate their environmental, social, and governance (ESG) performance. The CSRD expands upon the existing Non-Financial Reporting Directive (NFRD), mandating comprehensive sustainability reporting for a wider range of companies, including small and medium-sized enterprises (SMEs) that meet specific thresholds. The EU Taxonomy complements the CSRD by providing a standardized classification system to assess the environmental sustainability of economic activities, offering a clear framework for evaluating alignment with the EU's climate and environmental objectives (Directive (EU) 2022/2464 of the European Parliament and of the Council of 14 December 2022 Amending Regulation (EU) No 537/2014, 2022; Regulation - 2020/852 - EN - Taxonomy Regulation - EUR-Lex, 2020).

In the context of public procurement, the CSRD and EU Taxonomy have far-reaching implications. Public administrations will need to integrate sustainability criteria into procurement workflows, requiring suppliers to provide detailed ESG performance data as part of the qualification process. This shift aligns procurement practices with broader EU objectives, such as achieving carbon neutrality and promoting sustainable development. Furthermore, this is a development towards less strictly awarding based on financial criteria, which has been long awaited by literature (Qiao & Cummings, 2003; Sönnichsen & Clement, 2020). However, it also places additional compliance obligations on economic operators, necessitating robust governance, risk, and compliance (GRC) frameworks to manage ESG reporting effectively (Hummel & Bauernhofer, 2024).

The requirement for standardized sustainability data under the EU Taxonomy highlights the critical role of interoperability. Public administrations will need interoperable systems to process and verify ESG data, ensuring consistency and comparability across suppliers. Economic operators, in turn, must adopt technologies that facilitate accurate data collection and reporting, reducing the risk of non-compliance. While these regulations drive progress toward sustainability, they also introduce challenges, including increased administrative workloads and potential barriers for smaller suppliers. Capacity-building initiatives and collaborative efforts will be essential to ensure equitable participation in public procurement processes.

4.4 Carbon Border Adjustment Mechanism (CBAM)

The Carbon Border Adjustment Mechanism (CBAM) is a pivotal regulatory tool introduced by the European Union (EU) to address carbon leakage and promote global climate objectives. CBAM imposes a carbon price on imports from non-EU countries that do not meet the EU's stringent emissions reduction standards. Initially focusing on sectors such as cement, iron and steel, aluminum, fertilizers, and electricity, the regulation aims to level the playing field for EU industries subject to the Emissions Trading System (ETS), while encouraging international partners to adopt greener practices (Regulation - 2023/956 - EN - Cbam Regulation - EUR-Lex, 2023).

For public procurement, CBAM presents both opportunities and challenges. The inclusion of carbon pricing in procurement evaluations aligns with the EU's broader sustainability goals, incentivizing the selection of suppliers with lower carbon footprints. Public administrations will need to integrate CBAM criteria into procurement frameworks, necessitating the assessment of carbon-related metrics during the supplier qualification and evaluation phases. This shift emphasizes the need for transparent and interoperable systems capable of verifying and reporting carbon emissions data accurately.

Tab. 2 – Solution Mapping Matrix.

Regulation	Solution	EO / CA	Description	Sources
CBAM	GRC-Software and solutions	EO	GRC software enables economic operators to monitor, calculate, and report carbon emissions to comply with CBAM requirements. It simplifies the management of cross-border trade data and ensures accurate adjustment calculations.	(Ambec, 2022; Lim et al., 2021; Racz, Weippl, & Seufert, 2010; Racz, Weippl, Seufert, et al., 2010; Regulation - 2023/956 - EN - Cbam Regulation - EUR-Lex, 2023; Vicente & Mira Da Silva, 2011)
CBAM	Development of new standardized approaches and data specifications	CA	CAs can develop standardized data templates and formats to streamline reporting and evaluation processes for carbon emissions, facilitating compliance with CBAM during procurement.	(Ambec, 2022; Gal & Rubinfeld, 2018; Lim et al., 2021; *Regulation - 2023/956 - EN - Cbam Regulation - EUR-Lex*, 2023; Schmitz & Wimmer, 2023; Siapera et al., 2023)
EU-Taxonomy	GRC-Software and solutions	EO	EOs can implement GRC tools to assess activities against EU-Taxonomy criteria, ensuring compliance and readiness for classification and reporting obligations tied to sustainable finance.	(Hummel & Bauernhofer, 2024; Racz, Weippl, & Seufert, 2010; Racz, Weippl, Seufert, et al., 2010; Regulation - 2020/852 - EN - Taxonomy Regulation - EUR-Lex, 2020; Vicente & Mira Da Silva, 2011)
EU-Taxonomy	Usage of qualification methods (e.g. ESPD)	CA	CAs can utilize qualification methods like the ESPD to assess suppliers' alignment with the EU-Taxonomy framework, ensuring sustainable activities are prioritized in procurement. This would necessitate the extension of said standards to incorporate EU Taxonomy-related criteria.	(Hummel & Bauernhofer, 2024; Qiao & Cummings, 2003; *Regulation - 2020/852 - EN - Taxonomy Regulation - EUR-Lex*, 2020; Siapera et al., 2023; Telles, 2017)
CSRD	GRC-Software and solutions	EO	EOs can deploy GRC software to automate and verify the accuracy of sustainability reports, improving data integrity and compliance with CSRD obligations.	(Directive (EU) 2022/2464 of the European Parliament and of the Council of 14 December 2022 Amending Regulation (EU) No 537/2014, 2022; Hummel & Bauernhofer, 2024; Racz, Weippl, & Seufert, 2010; Racz, Weippl, Seufert, et al., 2010; Vicente & Mira Da Silva, 2011)
CSRD	Development of new standardized approaches and data specifications	Both	Developing standardized reporting templates would help EOs to align with CSRD requirements by enabling structured sustainability disclosures that meet regulatory standards. At the same time, it would make it easier for CAs to verify the compliance.	(Gal & Rubinfeld, 2018; Schmitz & Wimmer, 2023; Siapera et al., 2023; Vicente & Mira Da Silva, 2011) (Hummel & Bauernhofer, 2024)
CSDDD	Usage of qualification methods (e.g. ESPD)	Both	EOs can adopt ESPD or equivalent qualification tools to demonstrate compliance with CSDDD obligations, such as human rights due diligence and environmental risk assessments.	(Directive - EU - 2024/1760 - EN - EUR-Lex, 2024; LkSG - Nichtamtliches Inhaltsverzeichnis, 2021; Gervais et al., 2023; Gurtu & Johny, 2021; Okoye et al., 2024; Schilling-Vacaflor & Gustafsson, 2024; Telles, 2017; Weihrauch et al., 2023)
CSDDD	GRC-Software and solutions	EO	EOs can use GRC tools to ensure and monitore adherence to CSDDD obligations, ensuring effective implementation of due diligence across supply chains.	(Directive - EU - 2024/1760 - EN - EUR-Lex, 2024; LkSG - Nichtamtliches Inhaltsverzeichnis, 2021; Gervais et al., 2023; Gurtu & Johny, 2021; Okoye et al., 2024; Racz, Weippl, & Seufert, 2010; Racz, Weippl, Seufert, et al., 2010; Schilling-Vacaflor & Gustafsson, 2024; Smit et al., 2021; Vicente & Mira Da Silva, 2011; Weihrauch et al., 2023)

Economic operators involved in public procurement must adapt to the CBAM framework by investing in emissions tracking and reporting capabilities. Suppliers from non-EU countries face additional compliance obligations, potentially increasing the cost of imported goods. While these measures promote sustainable practices, they may also limit the participation of smaller suppliers or those from regions with less developed regulatory frameworks. Despite these challenges, CBAM offers significant potential to drive systemic change. By internalizing the environmental costs of carbon-intensive products, the mechanism fosters innovation in cleaner production methods (Ambec, 2022). Other Authors argue that CBAM is not economically viable because of increased costs (Lim et al., 2021). To address compliance complexities and support equitable participation, capacity-building initiatives and international collaboration will be essential.

5. Implementation of regulations

The effective implementation and management of emerging EU regulations requires robust governance, risk, and compliance (GRC) processes. GRC frameworks provide a structured approach to navigate complex regulatory landscapes, ensuring that both public administrations and economic operators (EOs) can comply with legal requirements while optimizing resources and mitigating risks. By integrating GRC processes, organizations can manage regulatory obligations systematically, aligning compliance efforts with broader strategic goals.

To create the solution matrix in **Tab. 2**, we cross-referenced the findings from the regulation matrix in **Tab. 1** with solution approaches identified in the literature. Challenges were grouped by recurring themes (e.g., data complexity, reporting burdens), and solution mechanisms were mapped using both academic sources and implementation guidelines from EU institutions. This mapping supports targeted implementation planning and represents a core design artifact in our DSR approach. Successful implementation of the identified solutions depends not only on technical feasibility but also on organizational adoption. Public agencies must manage change effectively by training procurement officers, aligning internal workflows, and building trust in GRC-based tools. Resistance to change, especially in resource-constrained municipalities, remains a critical barrier that must be addressed alongside technical innovation.

6. Impact on current standards

The introduction of new EU regulations, particularly the Corporate Sustainability Reporting Directive (CSRD), the Corporate Supply Chain Due Diligence Directive (CSDDD), and the EU Taxonomy Regulation, has revealed several gaps in existing public procurement standards. The gaps primarily stem from the increased complexity and specificity of the reporting requirements introduced by these regulations onto public procurement. To ensure effective compliance, both Economic Operators (EOs) and Contracting Authorities (CAs) must address these challenges while avoiding inefficiencies and inconsistencies in the procurement process. The enhancement proposals presented in this section were developed by analysing the specific challenges identified in the regulation and solution matrices. Each proposed measure directly corresponds to at least one major gap found in procurement standardization and was assessed against feasibility and scalability criteria by the authors of this paper, which were also discussed along different meetings with the cooperation partners in the Cooperation Project Digital Procurement.

6.1 Gaps in the current standardization landscape

The CSRD and CSDDD require organizations to provide detailed sustainability and due diligence reports. However, these regulations fail to define standardized formats for generating and sharing such reports. For instance, while the European Sustainability Reporting Standards (ESRS) under the CSRD provide a comprehensive legal framework, they are highly complex and challenging to implement. Larger organizations with robust compliance mechanisms may struggle with the requirements but be able to tackle them somehow. However, for Small and Medium Enterprises (SMEs), these obligations may appear insurmountable due to the intricate technical details and lack of clear guidelines.

The lack of standardization impacts not only the EOs. CAs and auditors responsible for evaluating these reports face significant data governance related challenges, including: Inconsistent Data Quality; Process Inefficiency; Lacking transparency and system interoperability. Without standardized reporting formats, data from EOs will likely vary in quality, completeness, and structure. The lack of consistency and traceability in data reporting raises concerns about transparency and accountability in public procurement. Existing procurement standards, such as the European Single Procurement Document (ESPD), are not designed to handle the complexity of these new regulatory requirements. While ESPD contains related criteria, its current structure would be overburdened by the volume and specificity of the information required by the new regulations.

6.2 Potential solutions and enhancements to the status quo – a roadmap

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

To address the gaps in current procurement standards and meet the demands of new EU regulations such as the CSRD, CSDDD and EU Taxonomy, it is essential to introduce targeted updates and complementary solutions. These measures must not only enhance the adaptability of existing frameworks but also streamline compliance processes for both EOs and CAs. The following roadmap provides an integrated approach by outlining potential solutions and their corresponding benefits:

1. **Utilizing the ESPD Framework:** The European Single Procurement Document (ESPD) is well-positioned to serve as a foundation for integrating new regulatory requirements, especially for EO qualification. However, to accommodate obligations under the CSRD, CSDDD, and EU Taxonomy, the ESPD must be extended to include new qualification criteria. These criteria should address critical areas such as sustainability reporting, human rights due diligence, and environmental risk assessments. This adaptation would ensure that the ESPD remains a versatile tool for managing the increasing complexity of procurement standards without fundamentally altering its core structure.

2. **Specialized Standards for Complex Reporting Criteria:** Given the high complexity of the reporting requirements introduced by the new regulations, it is advisable to create distinct, standardized formats for each type of report. For example, sustainability reports aligned with the ESRS could be simplified for usability by SMEs, while supply chain due diligence templates and environmental impact assessments could be standardized to ensure consistency across industries. These standalone standards would mitigate the risk of overwhelming the ESPD structure and ensure a clear and manageable reporting process for EOs and CAs.

3. **Integration Through Evidence Documents:** To facilitate the seamless inclusion of these complex reports within procurement workflows, standardized reports should be treated as evidence documents. These technical documents could be attached to the ESPD during the pre-award phase, providing CAs with all necessary information while preserving the integrity of existing procurement processes. This approach would enable automated processing and verification of evidence documents, reducing administrative burdens and enhancing evaluation efficiency.

4. **Leveraging GRC Software Solutions**: The technical intricacies of the new reporting obligations necessitate the use of advanced Governance, Risk, and Compliance (GRC) software. These tools can assist EOs in generating compliant reports with consistent data quality and accuracy. Additionally, GRC solutions can support CAs by enabling efficient evaluation of submitted reports, improving data governance, and ensuring compliance with the regulatory framework. Such software solutions should be designed with interoperability in mind, ensuring seamless integration with existing procurement systems and standards.

5. **Alignment with the Pre-Award Process:** The design of new standards and reporting templates must align closely with the pre-award phase of public procurement. By doing so, the data collected and reported by EOs can be directly applied to qualification and evaluation criteria, minimizing redundancies and streamlining compliance efforts. This alignment would ensure that new regulatory requirements are embedded into procurement workflows without disrupting operational efficiency.

7. Discussion

In this paper, we offer three primary contributions: First, we identify and categorize EU regulations from 2021–2027 based on their impact on public procurement, forming the basis of a structured regulation matrix. Second, we map these regulations to solution components that illustrate how GRC systems can address regulatory challenges. Third, we propose enhancements to current procurement standards, particularly the ESPD, and outline a roadmap for integrating GRC into future procurement workflows. Together, these contributions show how GRC frameworks can enable legal interoperability, operational resilience, and regulatory compliance.

While supply chain management has been extensively researched over decades, sustainability and ESG topics are comparatively underexplored, reflecting their recent emergence in regulatory and industry priorities. GRC systems are critical enablers of interoperability, particularly legal interoperability, by aligning governance, risk, and compliance processes across jurisdictions. However, a significant challenge lies in the fragmented nature of existing approaches, which either address GRC generically or narrowly focus on specific regulatory topics. This lack of integration underscores a research gap: the need for comprehensive frameworks that combine domain-specific expertise with advanced technological solutions.

While overall the topic of upcoming regulations might seem like a future issue, which has minimal impact on current procurement procedures, its substantial impact over the next few years should not be underestimated. Growing scarcity of resources, demographic challenges, and the raising necessity for regulations make a solid GRC management as outlined in this paper paramount to meet the challenges of tomorrow. As the transformation and

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

practical implementation of standards has proven to be a lengthy process, this research highly advocates to start the important development steps towards integrating GRC management into interoperability design now. Beyond technical solutions, this study underscores the need for organizational readiness in adopting GRC frameworks. Stakeholders across public procurement systems—IT managers, compliance officers, procurement leads—must align on shared goals, data protocols, and evaluation criteria. Future work should, therefore, assess how varying organizational capacities affect GRC adoption and outcomes in different EU member states.

8. Conclusion and further research needs

This paper has investigated new and recent EU regulations, and how regulatory dependencies affect public procurement and interoperability. We identified GRC solutions as critical enablers for efficient adoption of regulations and legal interoperability. As core contributions, we developed a matrix of EU-regulations and an assessment of their impact on public procurement. Based on this analysis a second matrix has been developed to map potential solution components to the core challenges associated with highest impact on public procurement. Finally, we synthesized the findings of both matrixes into three concrete gaps, which current standards will face when trying to adopt the new regulations. Furthermore, five enhancements were put forward to the current standardization landscape that might help to overcome these gaps.

While the paper produced a good initial structured overview of future challenges, research gaps, and potential solutions, the individual solution components are not discussed in the needed degree of detail. The application of GRC and interoperability design for topics like CSRD, CSDDD etc. is a very complex topic and has to be addressed by separate studies individually. Furthermore, the proposed harmonization of domain expert knowledge and technical solutions requires further specification.

Future research can build on the findings of this study to address the limitations of this research. First, the development of a scalable GRC framework that prioritizes interoperability is essential to enable efficient regulatory compliance across different sectors and jurisdictions. Second, research should explore how to effectively integrate domain-specific expertise with technical solutions to create adaptable and practical compliance mechanisms. Third, the application of artificial intelligence to both the development and auditing of regulatory reports represents a promising but underutilized area, with potential to streamline reporting processes and improve evaluation accuracy. Finally, focused studies on individual regulatory packages, such as the CSRD or CSDDD, are needed to address their unique requirements and implications for public procurement. This will be instrumental in fostering legal interoperability, improving compliance processes, and ensuring that public procurement systems remain robust and adaptive in the face of ongoing regulatory changes. A promising avenue for future research lies also in the application of artificial intelligence (AI) for sustainability reporting and regulatory evaluation. AI systems could enhance the quality and consistency of data-driven reports, automate compliance checks, and generate actionable insights for procurement officers. However, this requires further exploration, especially regarding data governance, bias mitigation, and SME accessibility.

Acknowledgement

This research is partially conducted along the “Cooperation Project in Public Procurement”. The authors are particularly grateful for the fruitful discussions within the teams of the different partners from the Federal Ministry of the Interior, the Federal Procurement Agency, and the Federal States Bremen, North Rhine-Westphalia and Rhineland-Palatinate. The opinions presented in this paper are solely those of the authors.

Funding

The “Cooperation Project in Digital Public Procurement” was partially funded by the IT Planning Council and FITKO in the time frame of 2023 – 2025.

Submitted: 31 January 2025, Revised: 26 March 2025, Accepted: 21 April 2025, Published: 21 May 2025

Abstract. This paper analyses the generation of public value through the adoption of government blockchain networks by different entities of the Brazilian federal government. To this end, the theory of Public Value in Electronic Government is used, with the approach proposed by Twizeyimana & Andersson (2019) with six dimensions of analysis. The method is a multiple case study with the three Brazilian blockchain networks: RBB, RNDS and PIER, which are at different stages of development. The results indicate the governance is a common challenge identified, and exchanging information with other networks is seen as a way of learning and developing the own models. Indeed, the already implemented government blockchain networks (RNDS and PIER) generate public value in the six dimensions and that the RBB has the potential to generate public value in the same dimensions. Furthermore, the choice of blockchain technology was an efficient solution for PIER and RNDS when compared to other technologies available at the time. The RBB was created to be an infrastructure for the development of other blockchain artifacts, to later house applications using the same technology. Governance challenges and balance between participants are crucial aspects in the development of networks. While RBB, a top-down initiative (governance development prior to applications) seeks a stable balance, the hierarchical deployment of PIER and RNDS allows for faster progress of deployment and development of applications on these networks. The paper has limitations in analysing public value from the perspective of public managers and not from co-creation with citizens. As future research, we suggest approaching the cases from the perspective of innovation theories and an investigation of the blockchain ecosystem in government in Brazil.

Keywords. government blockchain network, public-value, e-government, case study.
Research paper, DOI: https://doi.org/10.59490/dgo.2025.979

1. Introduction

The 2008 financial crisis, among other things, sparked a global sense of distrust (De Filippi et al., 2020). In the same year blockchain technology was introduced to the world with the launch of Bitcoin, and it was quickly identified that beyond its use in digital currencies, the technology had potential applications in electronic documents, such as identities, smart contracts, and property titles (Ølnes, Ubacht & Janssen, 2017).

Bitcoin and other blockchain-based systems were presented as a reliable alternative to existing financial institutions and even governments (De Filippi et al., 2020). In other words, the technology emerged as a mechanism for generating trust between people, regardless of any institution. Studies show the potential for use in governments, with the possibility of gains in efficiency, effectiveness, increased transparency, greater public participation, higher data reliability, among others (Ølnes, Ubacht & Janssen, 2017; Khan, Arshad & Khan, 2020; Allessie et al., 2019; Aristidou & Marcou, 2019).

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Governments worldwide have shown interest in the technology, especially for expected improvements in transparency, governance, and resource distribution (Batubara, Ubacht & Janssen, 2018). Beyond the applications and artifacts developed in blockchain, some countries have started to develop their own governmental networks, aiming to be platforms for blockchain applications.

Examples of these networks are the multi-country Alastria (mostly European states) and Lacchain (Latin America), BSN - Blockchain-based Service Network (China), and in Brazil, RBB (Brazil Blockchain Network), PIER (Regulatory Entities Information Integration Platform), and RNDS (National Health Data Network). In Academia there are studies on the characteristics of blockchain and potential applications in government, case studies, artifact design, and governance discussions (Christidis & Devetsikiotis, 2016; Ølnes, Ubacht & Janssen, 2017; Zheng et al., 2017; Batubara, Ubacht & Janssen, 2018; Allessie et al., 2019; Scholl & Rodríguez-Bolívar, 2019; Alketbi, Nasir & Abu Talib, 2020).

However, specific studies on governmental blockchain networks are still limited, demonstrating that research on this topic still does not cover the reality of seeking to implement the technology in governments. Additionally, papers on blockchain in government lack theories that help explain the phenomena, representing a significant gap in the Electronic Government literature (Atzori, 2018; Covarrubias & Covarrubias, 2021; Falwadiya & Dhingra, 2022).

In this context, the aim of this paper is to identify the public values generated through the adoption of governmental blockchain networks at the federal level in Brazil. With a positivist approach, this paper presents a multiple case study of the three federal governmental networks in Brazil that utilize blockchain technology: RBB, PIER, and RNDS. More specifically, the phenomenon under study is the blockchain networks of federal public administration entities in Brazil for their own and/or third-party applications, whether governmental entities or not.

The paper employs the theory of Public Value in Electronic Government utilizing the framework proposed by Twizeyimana & Andersson (2019), which suggests six dimensions associated with public value generation: Improved Public Services, Improved Administrative Efficiency, Open Government Capabilities, Improved Ethical Behaviour and Professionalism, Improved Trust and Confidence in Government, and Improved Social Value and Well-Being. Interviews were conducted with nineteen participants who worked on the implementation of the cited networks, and consultations were made to documents and institutional websites.

The results indicate that blockchain governmental networks can generate public value even before their full implementation, as by bringing stakeholders together in the process, value generation can already be identified in the dimension of improvement in administrative efficiency, with greater collaboration, cooperation, and improved communication among entities. Other dimensions such as the improvement of public services, enhanced ethical behaviour and professionalism, increased trust in government, and better social value and well-being were also identified in the implemented networks PIER and RNDS.

The paper is divided into six sections. This first section introduces the topic, presenting the main concepts. In the next section, the Literature Review is presented, highlighting the main research gaps. Section 3 presents the Method, detailing the multiple case study. Next, Section 4 presents the description of each one of the cases. Section 5 shows the results analysis. The last Section presents the Conclusion, including final considerations, limitations, and suggestions for future research.

2. Literature Review

2.1 Public Value and Electronic Government

Just as New Public Management (NPM) supplanted traditional public administration in the 1980s and 1990s, the concept of public value emerged as the response that many scholars sought for a new approach to government management, incorporating the necessary aspects for its practical and theoretical implementation as a replacement for NPM (Bryson, Crosby & Bloomberg, 2014). Public Value, as a public administration paradigm, was originated in educational disciplines at Harvard University, later gaining new interpretations with Mark Moore in the mid-1990s. Moore emphasized that public managers should make decisions while simultaneously acting collaboratively to generate outcomes that create value for the public (Hilgers & Ihl, 2010; Williams & Shearer, 2011; Cordella & Bonina, 2012).

Public value, in the context of public administration, can be understood as a counterpoint or alternative to NPM (Van Veenstra, 2012; Stoker, 2006). In NPM, the citizen is merely seen as a client; however, in the Public Value paradigm, individual preferences are considered essential for constructing the public interest, rather than being reduced to mere consumer preferences (Alford & O'Flynn, 2009).

To create public value, individuals must be able to express their preferences and needs, enabling the government

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

to leverage technology to enhance its capacity to deliver what citizens need and desire. In this process services are provided, and public value is created (Lopes, Luciano & Macadar, 2018). For the real perception of public value requires its creation first, which can be attained through the benefits derived from adopting a given service (Alshibly & Chiong, 2015). On the other hand, another perspective suggests that public value creation can be based on collective benefits rather than necessarily being of personal perspective (Alford & O'Flynn, 2009).

From a perspective in which public value creation is government-driven rather than necessarily co-created with citizens, Twizeyimana & Andersson (2019) conducted a literature review proposing six dimensions associated with public value and e-government: improved public services; greater administrative efficiency; Open Government (OG) capabilities; enhanced ethical behaviour and professionalism; increased trust in government; and improved social value and well-being. These dimensions can be categorized into three broader public value dimensions: enhanced public services, improved administration, and increased social value.

Regarding research on public value and e-government, Twizeyimana & Andersson (2019) identified a lack of studies on the value of e-government in developing countries, highlighting the need for further research at different levels of government. Additionally, Lopes, Luciano & Macadar (2018) assert that the topic of public value remains underexplored in Brazilian research and government services.

2.2 Blockchain and Government Networks

Regulatory and legal issues related to the principles of public administration must be respected to ensure the validation and proper use of blockchain technology by the public sector. Beyond digital currency applications, smart contracts enable government operations to benefit from increased transparency, trust, efficiency, reduced corruption, cost reduction, fraud prevention, decreased manipulation, and enhanced resilience and security (Ølnes, Ubacht & Janssen, 2017).

Blockchain is a distributed public ledger in which all transactions are stored in blocks, with new blocks continuously added. Security is based on asymmetric cryptography and distributed consensus algorithms, typically characterized by decentralization, persistence, anonymity, and auditability (Zheng et al., 2017). Blockchain technology is expected to play an increasingly important role in global economic recovery and the development of the digital economy following the pandemic (Yang et al., 2022).

Ølnes, Ubacht & Janssen, 2017 (2017) argue that blockchain technology can be applied beyond the private sector to government operations. They compiled a list of the primary benefits of adopting blockchain applications in government, which include transparency, trust, efficiency, reduced corruption, cost reduction, fraud and manipulation prevention, increased resilience, and improved security. However, the authors emphasize that these benefits are unlikely to be achieved simultaneously.

Governments can leverage blockchain to transform how they manage data and interact with citizens. This technology is particularly suitable for the digitization of government services, and its potential to enhance efficiency is a key driver of adoption (Saxena et al., 2022). Although still in its early stages, efforts have been made by governments to implement blockchain in public services across different domains: government-to-government (G2G), government-to-business (G2B), and government-to-citizen (G2C). These initiatives aim to streamline processes, strengthen security, enhance transparency, and improve privacy in e-government services (Lykidis et al., 2021).

Governmental blockchain networks are characterized by an infrastructure developed by public entities, serving as a foundation for government-related applications. Such networks are being adopted in various countries worldwide. According to Stockton (2020), the main obstacle to blockchain adoption has been the cost and complexity of setting up a platform, making the emergence of networks such as China's BSN (Blockchain-Based Network) or similar solutions inevitable.

Some notable examples of these networks are listed as follow. Alastria is an association open to all types of companies and organizations, including public entities, with the mission to engage various sectors and contribute to the creation of a diversified innovation ecosystem. Participants collaborate on both network infrastructure and application development (Alastria, 2021). Another significant example is LACChain, a global alliance comprising various blockchain stakeholders and led by the Inter-American Development Bank's Innovation Lab (BID Lab). LACChain focuses on fostering blockchain adoption in Latin America and the Caribbean, promoting financial inclusion, consumer protection, and market integrity (Lacchain, 2021).

The European Blockchain Services Infrastructure (EBSI) is another relevant initiative. Established in 2018, EBSI connects blockchain nodes across 29 countries (EU member states, Norway, and Liechtenstein) along with the European Commission. Its vision is to leverage blockchain to develop cross-border services for public administrations and their ecosystems, ensuring information verification and reliable service delivery. Since 2020,

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

EBSI has been implementing a distributed blockchain network across Europe to support applications focused on various use cases (EBSI, 2021; Falwadiya & Dhingra, 2022).

The Argentinean Federal Blockchain Network (BFA) was created in 2018, with validation nodes operated by public institutions (such as universities) and private companies (Ramirez-Escudero, 2021). The BFA is an open, multi-service, and participatory platform designed to integrate services and applications that drive technological innovation and collaborative governance. Key use cases include public procurement, academic certificates, financial guarantees, and food trade (BFA, 2022).

Specifically in Brazil, three blockchain networks are under development at the federal level. PIER is an initiative launched in April 2020 by the Central Bank of Brazil (BACEN), the Superintendence of Private Insurance (SUSEP), and the Securities and Exchange Commission (CVM). Its objective is to facilitate the exchange of information among these institutions (BACEN, 2022; SUSEP, 2022). The RNDS, led by the Ministry of Health, serves as a repository for citizens' health records, integrating health-related data and supporting the management of healthcare services across different levels of care (Datasus, 2020). The RBB, developed through a Technical Cooperation Agreement between The Brazilian Development Bank (BNDES) and the Federal Court of Accounts (TCU) was designed as a nationwide infrastructure. RBB aims to serve as a platform for developing applications of public interest (BNDES, 2022).

This growing adoption of blockchain by governments highlights its potential to improve transparency, efficiency, and security in public administration. However, its successful implementation requires overcoming technological, financial, and regulatory challenges, as well as fostering collaboration between government entities, the private sector, and civil society.

3. Method

The method of this paper is the case study, incorporating document analysis and in-depth interviews with key participants involved in the implementation of blockchain government networks, which includes public managers, academics, market professionals, and other experts. The case study method fits for the objective of exploring contemporary phenomena within a societal context, and it is particularly relevant when the phenomenon under study is broad and complex, requiring a holistic and in-depth analysis (Yin, 2018). The methodological framework follows the approaches outlined by Yin (2018) and Eisenhardt (1989).

The object of study in this research is the phenomenon defined in this paper as governmental blockchain networks. Blockchain applications, by definition, are network artifacts; however, the mere adoption of a blockchain application by a government does not imply that it is using a network in its strictest sense or fully embracing the technology's main principles. Thus, this study focuses specifically on developments that explicitly identify themselves as networks. Consequently, blockchain applications confined to a single institution or lacking the intent to integrate multiple entities are not considered within the scope of this research. The study, therefore, examines self-declared blockchain networks in federal level of the public administration in Brazil, designed for both proprietary and third-party applications, whether governmental or non-governmental entities. Three blockchain networks at different stages of development were selected in the Brazilian context: PIER, RNDS, and RBB.

There are some reasons for choosing these three networks. First, they are all existent government networks in Brazil at federal level, which can produce rich comparison, once they are at the same regulatory and legal environment and face common challenges. Second, as studies comparing blockchain networks are scarce in the literature, this movement seems to be prudent in the theorical contributions. Third, the authors had an easier access to the interviewers as they are residents in Brazil.

The PIER, developed by the Central Bank of Brazil (BACEN), was officially launched in April 2020 to facilitate the exchange of information between the Superintendence of Private Insurance (SUSEP), the Central Bank (BACEN), and the Securities and Exchange Commission OF Brazil (CVM). Its primary function is to integrate data from regulatory bodies and streamline authorization and registration processes within the financial system (SUSEP, 2022). PIER enables financial institutions to receive responses from regulatory agencies more swiftly and efficiently (BACEN, 2022).

The RNDS serves as a document repository for storing citizens' health information, establishing a federated interoperability layer that supports the development of various health applications, such as the Brazilian Electronic Health Record (Datasus, 2020). The RNDS represents an innovative approach to health data management, storing information in virtual cloud-based containers using blockchain technology. It works as a repository for retrospective, real-time, and prospective patient data in digital format (Datasus, 2020).

The RBB was originated as a project in the BNDES to establish a nationwide blockchain infrastructure. The network aims to integrate all three branches of government—executive, legislative, and judiciary—along with federal

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

agencies, state, and municipal entities. Its objective is to provide a robust infrastructure that enables both public and private actors to develop and operate blockchain-based applications of public interest (BNDES, 2022).

3.1 Respondents and coding

The respondents of the research were individuals involved in the implementation and management of the networks. More specifically, interviews were conducted with the technical managers responsible for each network, as well as the managerial staff overseeing these networks. This approach incorporated perspectives on both the execution and organizational aspects of the networks. Based on recommendations from some interviewees, individuals from entities associated with the networks were also interviewed, as they could provide clarifications on decisions that impacted the network. All interviews were conducted by the first author as the sole interviewer. The first interview took place on December 12, 2022, and the last on February 10, 2023.

All meetings were held virtually via the Microsoft Teams platform, with recording and transcription features enabled. The meetings were conducted individually, with an average duration of forty-six minutes. The only exceptions were the meetings involving teams from the Central Bank and SUSEP. In these two meeting the participants requested to join simultaneously. In total, 19 individuals were interviewed, each representing a specific network, holding mid-level management positions or high levels of technical responsibility.

The interviews were recorded, transcribed, and analysed using coding, thematic analysis, and data tabulation. The transcription was initially read with open coding, followed by a second stage where these codes were grouped into final categories, as outlined below:

i)Origin: This topic includes themes related to the emergence of each network, including the motivation behind its creation, the reasons for its specific structure, its objectives, and other relevant aspects.

ii) Background and conditioning factors: This section addresses the circumstances preceding the networks' emergence, such as the conditions in which they were developed, the antecedents that enabled their creation, the willingness and capacity of the teams, internal leadership, technical aspects, and internal decision-making.

iii) Interinstitutional relations: This item identifies the partnerships and interactions established among the network actors, such as the creation of connections and dialogues essential for network formation.

iv) Leadership: Although networks assume a balance between participating entities, network governance remains a critical issue. It was identified that the networks exhibited some form of leadership, making this aspect fundamental to understanding Brazilian networks.

v) Governance and technical aspects: In line with the literature review, governance emerged as a key issue in the interviews. Additionally, governance is often associated with specific technical choices, and this section explores the relationship between these two concepts. The analysis highlights the technical decisions made within the networks that relate to governance themes.

vi) Outcomes and lessons learned: benefits and other gains obtained through the networks, as well as the lessons learned so far and those projected for the near future.

vii) Associated costs and challenges: This item evaluates the financial and non-financial costs associated with the networks, as well as other difficulties encountered throughout their evolution.

viii) Current status: A summary of the current state and operational dynamics of the network.

Other cross-cutting themes emerged in the research, were coded and analysed, but are not presented in this paper.

4. Cases Description

The RBB emerged from BNDES initiatives in blockchain (BNDES, 2022). According to Interviewee 1, the first actions related to blockchain at BNDES began with the development of a Token and, over time, the possibility of the project evolving into the creation of a network. The network was founded based on a Technical Cooperation Agreement between BNDES and TCU, at an event held on May 30, 2022 (TCU, 2022).

The RNDS emerged as a solution to a data integration problem in the public health sector. Interviewee 6 highlighted that the choice of blockchain was due to the greater adherence of the technology to the proposed objectives for the health network. It was initially conceived to be a system to integrate patients' health data, giving them access to doctors and the government. But still in its development, it had to undergo a transformation in its conception, due

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

to the Covid-19 Pandemic crisis. Thus, the structure was first used for the national registry of Covid-19 vaccines and tests. Interviewee 11 highlighted that there was a demand from the Ministry of Health to integrate health data, and the team concluded that the blockchain solution would be the most appropriate. However, at the same time, it quickly ceased to be regional and became federal, without time for pilot tests. Due to this urgency, Interviewee 12 mentioned that in this environment of rush and need for quick responses amid the Pandemic, the network was put into operation.

The first experience with blockchain at the Central Bank was a positioning paper of the IT team. This division conducted research on DLTs analysing possible use cases and examining some of the platforms available to develop prototypes of a settlement system by the Central Bank (Burgos et al., 2017). Interviewee 7 mentioned that PIER emerged as an initiative of the Central Bank to share relevant information, such as company registration data, financial information, market information, and other information that may be useful for the supervision and regulation process of the regulatory entities of the financial system. The following table presents the comparison between the networks.

Tab. 1 – Case study comparative analysis

Theme/ Network	RBB	RNDS	PIER
Creation	Infrastructure for the development of blockchain applications by public interest entities.	Solution for healthcare data integration.	Solution for exchanging information from financial system regulatory entities – automation between regulators.
Blockchain use in the network	Technology as the center of the development strategy.	Better adherence to the proposed objectives. Blockchain as a central part of the network, but with other associated technologies.	Better adherence to the proposed objectives. Complementary technologies for participant interface.
Formalization of network constitution	Technical Cooperation Agreement between BNDES and TCU with the later adhesion of the other participants.	Enforcement through normative acts of the federal government.	Technology established based on the previous relationship between institutions.
Conditions for the emergence of the network	Internal innovation project, with institutional sponsorship from senior management, which allowed for deeper insights into the topic. Coordination with other entities interested in the topic. Institutional sponsorship from other public administration entities for a national blockchain network. Other government entities with technical knowledge of blockchain. BNDES expertise in relations with public and private entities. Possible role as BNDES financier.	Pre-existing digital strategy and identification of blockchain as a suitable technology for the development of activities. Previous failed technological attempts that brought knowledge for implementation.	Pre-existing digital strategy and identification of blockchain as a suitable technology for the development of activities. Production of technical knowledge by teams (positioning paper) analysing technology and its applicability in Central Bank actions. Prior knowledge of processes to be digitized.

Network Guiding Artifact	The network as a platform for developing other blockchain applications.	System for exchanging health information.	System for exchanging information from financial sector regulators.
Leadership	Shared.	Centralized.	Centralized.
Dialogue between network entities and power balance	Negotiation between entities for the best development of the network. Search for the lack of hierarchy between participants.	Guidance on the use of the Ministry for other entities and the respective provision of infrastructure. Existence of hierarchy among participants.	Negotiation between the Central Bank and other entities. Despite no hierarchy between entities, the conditions had a kind of enforcement for the adoption of the network by SUSEP and CVM. BACEN as the leader.
Development	Internal resources without hiring.	Internal resources: taking advantage of pre-existing cloud and service provision contracts.	Internal resources without hiring.
Governance	Public-permissioned network. Negotiation between entities to define by consensus how costs and resources will be shared. Technology presupposes another modus operandi of work, in which assets and operations are consensual and divided, which marks an opposition to the current centralization of involved entities.	Private network. Operating and sharing model defined by a single entity. Emergency implementation of the network meant that certain technical and governance aspects were left aside.	Private network. Operating and sharing model defined by a single entity. Network governance is more of a control by BACEN than a negotiation between the various parties that make it up, since the bank is the main actor and leader of the network.
Nodes	Distributed among participants physically. Each entity is responsible for its infrastructure. Exchange of knowledge between entities.	Even 3 for each participant, all in the same cloud structure. Ministry responsible for state infrastructure initially.	Distributed among participants, both physically and in the cloud. Each entity is responsible for its infrastructure. Central Bank with the role of technical advisor of other entities.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Benefits	Infrastructure that allows application development. Possibility of sharing developments and reducing costs. Exchange of information between participants. Encouraging use for public administration, internal discussion in court, positive media and the message to public managers that they can seek innovation. Potential cost reduction due to the pre-defined environment and exchange of developments. Encouraging the use of blockchain for other public sector entities. Intra-institutional: positive media, internal debate with other departments and improvement of the image of the bodies (as supporters of innovation). Technological capacity, coordination with other entities and creation of an environment for innovation.	Application of blockchain in the context of health data in government. Federalization of distributed data: data is placed on the network according to local standards and the system allows the consolidation of information. Covid-19 crisis response tool. Availability of the national covid-19 vaccination card in a timely manner. Centralization of Covid-19 exam and vaccine data, with rapid consolidation of information. Taking advantage of previous developments for new applications. Data infrastructure. Provision of information to the end user. Greater auditability of health expenditure (verification by citizens of medication use, for example). Learning to use cloud technology. Decentralized data consolidation at lower cost than other technologies.	Greater speed of response to the end user when appointing people to positions in financial institutions, for example. Less bureaucracy between entities. Agile dialogue between entities. Availability of teams for other intellectual activities. Fewer manual processes and associated rework risks. Auditability of processes. Institutional learning of in-depth theoretical and new practical knowledge that could be used for regulation in the future. Learning about blockchain technology that can help the development of Real Digital.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Costs	No financial outlay, development by an internal team. Infrastructure costs assumed by each entity. Insignificant infrastructure values. Network with effective return in the medium/ long term.	Taking advantage of internal contracts for network development. Allocation of consultants who would already be available to the Ministry. Use of a pre-existing cloud contract. Blockchain costs approximately 1/3 of an alternative. High initial cost for the Ministry, but later each state would assume its infrastructure cost. RNDS cost around 10% of the costs of previous similar projects.	No financial outlay, development by an internal team. Infrastructure costs assumed by each entity. Insignificant infrastructure values. Insignificant deployment values.
Difficulties	Cultural: initial acceptance by different public administration bodies. Articulation between entities and assembly, governance and establishment of consensus for decisions. Convincing technical areas to business (and decision-making) areas to join the network.	Definition of standards for information exchange. Rapid system implementation requiring quick responses. Lack of time to make a pilot. Difficulty implementing the “undo” or reversal system. Lack of adequate testing environment.	Reduced team for development and deployment. Reduced budget of resources for developing innovation projects. Responsibility for maintenance and support in partner environments. SUSEP and CVM in lower stages the technology knowledge.
Current status	Network founded. Under development, with the definition of governance and adhesion of new partners.	After a hacker attack on the cloud where the network was hosted, the network was resumed using another technology, which is still in force today. There is no prospect of a resumption of blockchain technology.	Network in operation according to initial forecast.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Learned lessons	Training and education within the institutions themselves, leaving technical environments and passing through other areas aiming at embracing innovation. Better for government applications to run on non-full public networks. It also applies to the development of networks	Need for communication and awareness among other actors, even if the application is enforced. A hybrid solution, which has local and cloud servers, designed to work in multiclouds. Applications of the size of RNDS require a maintenance and support team available to support them.	Top-down systems with the provision of technical support increase the speed of implementation but can limit the knowledge transfer. In-house system for experimentation in other uses (real digital).
Expected results in the future	Applications' development. Robust governance model.	Reactivation of the blockchain network. Electronic medical record with patient history available in real time to network participants. Consolidated history of information for patients and doctors, available in real time.	Possibility for the network to receive other applications, such as the SUSEP system directly with the user Knowledge and mastery of technology for other applications. Practical, operational knowledge of technology.

5. Results Analysis

The following table presents the KPIs, and dimensions identified for each of the networks in this research, characterizing them as a subset of the complete framework of Twizeyimana & Andersson (2019). Due to the different stages of the networks, there is a distinction between the public values identified and the potential public values that may be generated in the future by the networks.

Tab. 2 – Public values' KPIs

Public Value	**Identified**			**Potential**		
Improved Public Services	**RBB**	**RNDS**	**PIER**	**RBB**	**RNDS**	**PIER**
provision of services to citizens		**X**	**X**	**X**		
increased quality of public information and services		**X**	**X**	**X**		
enabled transparency, participation, and collaboration in the delivery of public services		**X**				
Improved Administrative Efficiency	**RBB**	**RNDS**	**PIER**	**RBB**	**RNDS**	**PIER**
cost-reduction		**X**	**X**			
reduced bottleneck and queues in the delivery of services to citizens		**X**	**X**	**X**		
better collaboration, cooperation, and better communication	**X**	**X**	**X**	**X**		
increased transparency, participation, and inclusiveness		**X**	**X**	**X**		
maintained accurate and durable records			**X**	**X**	**X**

increased citizens' access to government information and services		**X**				
maintenance of accurate durable records			**X**	**X**	**X**	
Improved Trust and Confidence in Government	**RBB**	**RNDS**	**PIER**	**RBB**	**RNDS**	**PIER**
better delivery of public services		**X**	**X**	**X**		
increased quality of public services		**X**	**X**	**X**		
Improved Social Value and Well-Being	**RBB**	**RNDS**	**PIER**	**RBB**	**RNDS**	**PIER**
achievement of better outcomes in areas of peace, security, poverty reduction, **public health**, high employment, low crime rates, clean streets, improved environment and better educational achievements.		**X**				
a more flexible, pervasive, and cost-effective public sector (e.g., provision of online applications and transactions)		**X**	**X**	**X**		

In each dimension of the framework, at least two KPIs of public valuer were identified. From an initial perspective, it is evident that the RBB, due to not being operational and lacking any use cases in operation, only indicates achievement in one KPI within the dimension of Improved Administrative Efficiency. However, it is the network with the greatest potential for the development of new KPIs, as a total of eleven indicators were identified across all dimensions of public value.

Each of the networks, individually, has at least one KPI in each of the six dimensions. In all analysed networks it was identified the generation of public values across all six dimensions. This suggests that, potentially, once a government assesses the suitability of implementing a governmental blockchain network, it will generate public value.

In the dimension “Improved Public Services”, both the RNDS and PIER were able to deliver new services in e-government. The RBB considers this value as one of its objectives. Similarly, RNDS and PIER reported perceived improvements in the quality of the information provided about their services. PIER achieved this by centralizing data from different agencies onto a single platform, while RNDS managed to federalize health data. Regarding transparency and collaboration in public service delivery, only RNDS shows be able to deliver this value, allowing citizens to track their health data, including medications, and report any discrepancies within the system.

In “Improved Administrative Efficiency”, four KPIs were simultaneously identified by all three networks: reduced bottleneck and queues in the delivery of services to citizens, better collaboration, cooperation, and better communication, increased transparency, participation, and inclusiveness, and maintained accurate and durable records. This result suggests that enhanced administrative efficiency, characterized by quicker processes, team collaboration, and citizen participation, are public values that can be strongly achieved through blockchain networks.

The dimension “Improved Administrative Efficiency was the only one in which an already identified public value was identified for the RBB. Even in the pilot phase the communication among the parties already ensures greater collaboration, cooperation, and improved communication among the entities. This KPI is also considered potential for this network, because once implemented, these processes can take place within the network.

Regarding cost reduction, RNDS indicated that the blockchain solution was less expensive than previous attempts, and PIER stated that the system freed up analysts from handling bureaucratic tasks to engage in more valuable activities. Both RNDS and PIER have shown that the networks generated efficiency in processes, delivering more services with fewer resources employed. They utilized pre-existing resources, but this KPI does not account for additional associated costs, such as training and the allocation of teams or the work hours dedicated before the

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

network's implementation.

On the KPI of "reduced bottleneck and queues in the delivery of services to citizens ", according to interviewees, if it were not for RNDS, there would have been no timely response regarding vaccination data at the onset of the pandemic. For PIER, this KPI meant the reduction of bureaucratic hurdles between regulatory bodies. Throughout the interviews, it became clear that the network serves as an efficient means to exchange data and an excellent locus for collaboration among entities. In terms of transparency, RNDS managed to provide greater visibility of information among entities and to the public, consolidating federal data. In contrast, PIER achieved this only among the entities that are part of the platform.

Regarding the KPI of accurate and durable records, RNDS demonstrated how the principles of the technology must be respected, even in a pilot phase. A network based on technology that anticipates data distribution, which is strongly resistant to hacking attacks, suffered losses due to a cloud attack rather than an attack on the network itself. This could compromise the data related to COVID tests and vaccinations. From this experience, the potential of the network was identified should it resume using blockchain technology and implement distributed nodes. In contrast, PIER possesses data integrity and distributed backups.

The networks still do not appear ready to develop the capacities for open government. Only RNDS has a system for public engagement (allowing citizens to verify their data and access aggregated information), thereby facilitating greater public control. RBB and PIER have the potential to develop this capacity within their activities. Thus, in the dimension of Ethical Behaviour, RNDS meets the KPI of greater access for citizens to government information and services. As previously explained, only PIER has demonstrated the maintenance of durable and accurate records, but this is a desired capability for the other two networks.

In the dimension "Improved Trust and Confidence in Government" both RNDS and PIER deliver better services on the blockchain than when these same services were on other systems, providing better service and improved quality in outcomes. The RBB is indicated to have this potential in its actions. Regarding "Improved Social Value and Well-Being", RNDS and PIER, as observed, alongside RBB potentially, utilize online transactions, making the public sector more flexible. However, when analysing specific sectors, only RNDS delivers value in the KPI of better health outcomes.

6. Conclusion

Following the public value framework in electronic government presented by Twizeyimana & Andersson (2019), the implementation of government blockchain networks at the federal level can generate the following public values: improvement of public services; greater administrative efficiency; improving open government capabilities; better ethical and professional behaviour; greater trust in government; and improving social value and well-being.

Theoretically, between networks there should be a balance between all participants. But what was verified with the research is that they all developed with one entity being the driver of the network. This was seen in PIER, RBB and RNDS, with the driving forces, respectively, being the Central Bank of Brazil, BNDES and the Ministry of Health. PIER is the only one that proposes to be strictly for federal level entities, being specifically for regulatory entities of the Federal Executive Branch. However, both RBB and RNDS, from the beginning and in their objective, have a multilevel characteristic.

The RBB, more directly, was structured to encompass federal, state and municipal entities, with the desire for this institutional variability. The RNDS, on the other hand, positioned itself as a network led by the Union, through the Ministry of Health, centralizing data from the Union itself, the 26 states and the Federal District. It is important to highlight that connection with municipal entities would be desirable, but this would not fit into the network. In this way, the possibility would be for the state entity to replicate the data federalization structure for its municipalities.

Concerning the networks implementation, when conducted top-down (where governance defines the artifact rather than the artifact defining the governance of the network), there seems to be greater potential for balanced role evolution among participating entities, as observed in the development of RBB. Conversely, when implemented within a hierarchical structure (where a company defines governance, thus establishing the conditions of the network), implementation occurs more rapidly, as seen in PIER and RNDS. This issue of balance versus speed is an aspect that could be explored in future research. Additionally, the more decentralized aspects the network possesses, the greater the need for interaction to facilitate its creation. However, even when there is a central entity driving the network's development, it is essential to establish a communication system for information sharing and training of other elements.

This work developed the study of the generation of public value from the perspective of public managers, experts and those who worked on the creation of government networks. The results obtained are robust within the

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Brazilian context, and the authors believe that these findings may be applicable in other countries or subnational entities. However, it is essential to conduct further research to determine whether such conditions are indeed confirmed in different scenarios. As a limitation, the paper doesn't consider the perspectives of public values being generated in joint creation between government entities and citizens. As a sequence, studies are suggested that encompass this perspective, in which citizens can be studied and the generation of values can be jointly evaluated. In this way, studies can be quantitative in nature, with the definition of indicators, which evaluate with the general population i) whether they have the same impressions as public managers or ii) whether the expected public values are in fact identified by the general population.

For future work the authors suggest the following research. This paper was developed through the theoretical lens of Public Value in Electronic Government, but during the process other opportunities were identified from other perspectives that were not explored in the literature used. For example, innovation theories can be used to analyse the development and implementation of technology in the public sector, including for the cases cited here. Furthermore, economic theories can also be evaluated for technology adoption. Finally, as this paper is restricted to the Brazilian case, future works can bring networks from other countries or even a cross-country analysis.

Acknowledgement

The Author 1 is grateful to Brazilian Development Bank – BNDES, their workplace, for the support provided throughout the research phase. He would also like to thank all the interviewees who kindly dedicated their time and shared information for the interviews that made this research possible.

Abstract. Public administrations are increasingly confronted with demands for greater citizen engagement and a shortage of qualified professionals. The adoption of emerging information and communication technologies (ICTs) is often shaped by organizational factors such as resource availability, leadership, and interorganizational dynamics. As digital transformation accelerates, virtual technologies, particularly virtual reality (VR) and augmented reality (AR), offer promising opportunities to enhance administrative processes through immersive and augmented environments. However, the integration of these technologies remains complex and presents numerous applicational challenges.

This study investigates the barriers to VR/AR adoption in the public sector, with a particular focus on organizational and adaptation-related issues. Additionally, it explores the potential of AI-powered chatbots to mitigate these barriers. To that end, a deductive thematic analysis was conducted on a sample of 104 VR/AR projects. The study further examines the synergies between VR/AR systems and AI chatbots.

The findings provide a foundational understanding of the applicational barriers associated with VR/AR integration in public administrations, highlighting challenges related to infrastructure, human–computer interaction, system stability, financial constraints, and complexity. While AI-powered chatbots show potential in addressing several of these issues, the study emphasizes the importance of designing both technologies as complementary systems to enhance effectiveness, efficiency, and user experience.

1. Introduction

Public administrations have come into a new era of captivating changes and technological advancements (Lnenicka et al., 2024). Innovative digital technologies offer new potential to address upcoming challenges, such as the high need for qualified specialists and the growing demand for citizen communication and involvement (Cortés-Cediel et al., 2023). Virtual technologies, including VR and AR, are promising rising technologies which could allow to introduce a new type of virtual citizenship. Discussed as a foundational layer for an omnipresent virtual internet, the metaverse increasingly appears to be an imminent rather than distant application (Ricoy-Casas, 2023). Virtual reality (VR) refers to technologies, which shutdown the reality and create a virtual environment to the eyes of a human participant. On the other hand, augmented reality (AR) refers to technologies, which enhance the field of view of a user (Suh & Prophet, 2018). Currently, both technologies show potential in a variety of fields where information needs to be vividly visualized (Renu, 2021). From virtual city tours, digital twins, to participation. Several cases exist, which use the technology to vividly display projects and public processes to the people (Suh & Prophet, 2018). In science-fiction movies, these virtual worlds are often populated with artificial inhabitants, such as virtual intelligent avatars or intelligent AI-companions (Ricoy-Casas, 2023). Already today, we encounter almost daily interaction with virtual avatars or conversational agents, such as Microsoft Cortana, Google Gemini, or ChatGPT (Casheekar et al., 2024). Known under the umbrella term chatbots, these are engaging tools which can

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

help to close the communication gap between citizens and administration through engaging and almost human like natural conversations (Androniceanu, 2023; Yeh et al., 2019).

In contrast to virtual and visualizing communication tools, such as VR and AR, chatbots can independently have a verbal or textual conversation with a human (Dwivedi et al., 2021). Recent chatbot systems implement AI algorithms. These systems have the ability to learn from real-time input and learn to adapt to it (Abbas et al., 2023). Chatbots have demonstrated applicability in scenarios that demand extensive and diverse verbal interactions. (Cortés-Cediel et al., 2023). For public administration, this shows to be effective in settings where a large number of citizen requests need to be processed. To this point, chatbots in public administrations have primarily been used for simple requests. However, the accessibility of more complex systems, including Large Language Models (LLMs), shows potential for more advanced settings. With these new opportunities, a chatbot could guide citizens through VR/AR-environments and assist citizens in a new and engaging way (Dwivedi et al., 2022).

A combination of both VR and AR technologies could be a powerful new way of citizen engagement (Dwivedi et al., 2022). However, currently only a few projects implement both technologies in an operationalizable way (Suh & Prophet, 2018). These projects are often experimental or require a noticeable effort (Hwang et al., 2024; Lnenicka et al., 2024). Therefore, it is still questionable if a combination of both technologies is applicable in the public sector in the present and future. Therefore, we want to investigate current VR/AR projects, identify challenges, and highlight the potential of a combination in the given fields. The findings of our paper are both valuable for science and public administrations, analysing the potential of a technological combination. The research questions of this paper are consequently:

RQ1: What are the current barriers of VR/AR adoption in the public sector?
RQ2: How can AI-powered chatbots help to reduce barriers in VR/AR adoption in the public sector?

To answer the research questions, we first outline the theoretical background on VR/AR and highlight the potential of AI-Chatbot applications in the public sector. We also present a first given state on the combination of both technologies for public services. When the theoretical context is given, we present our methodology of a deductive thematic analysis on the basis of 104 VR/AR projects in the public sector. We outline the codebook for the analysis of potential barriers to VR/AR adoption in the public sector. Based on this, the findings of our analysis are presented. We discuss the potential to address current barriers in VR/AR adoption with an AI-Chatbot combination and present our conclusions as well as limitations and possible future research.

2. Theoretical Background

Immersive technologies blur lines between physical and virtual worlds, creating a sense of presence and engagement for users (Suh & Prophet, 2018). Widely available in the consumer market, head-mounted displays (HMDs) are one prominent example of these technologies. These devices, worn on the head, immerse users in a virtual environment (VE) by stimulating their senses, allowing them to interact with virtual objects and representations (Cassani et al., 2020). In contrast, augmented reality covers a broader range of devices and applications. A major breakthrough in the commercial adoption of AR came with the release of the mobile app Pokémon Go in 2016, which popularized location-based AR experiences (Suh & Prophet, 2018). Since then, AR applications for smartphones and tablets have become increasingly common.

The second focus technology are chatbots. Chatbots are conversational agents, which allow adaptive conversations on certain topics. In public administration, chatbots have high potential to achieve more transparent processes while providing 24/7 access to governmental data sources. Chatbots may be found in a variety of public processes (Abbas et al., 2023). However, chatbots integrated today in public administrations are mainly for simple and experimental interaction cases (Cortés-Cediel et al., 2023).

A combination of VR/AR and chatbots is currently scarce in public projects (Lnenicka et al., 2024). In regard to science-fiction and virtual digital utopias, the combination is foreseen to be powerful as intelligent technology becomes integrated into our daily lives (Dwivedi et al., 2022). Possible fields of application are virtual medical assistants or virtual AI systems, which may be positioned in the real or virtual world (Chadha et al., 2023). Promising fields are also educational or cultural settings where both technologies can enhance the common effect and provide vivid input to the learner (Hwang et al., 2024).

3. Methodology

3.1. Thematic Analysis

In order to highlight the potential of a VR/AR and chatbot combination in the public sector, we analyze a dataset of 104 VR/AR projects on possible application fields. As shown in Figure 1, 59% of the highlighted projects in the datasets originate from Germany and the broader DACH region. Germany is a country with a highly complex

bureaucracy that encounters many challenges in the introduction of innovative digital technologies (Sept, 2020). Further projects were located in the USA (18%), additional European countries (Sweden, Finland, Ireland, Netherlands and the UK) and Australasian countries (Indonesia and Australia). To understand the potential of VR/AR and chatbot combination, we initially started with an analysis of current barriers that were experienced in the projects.

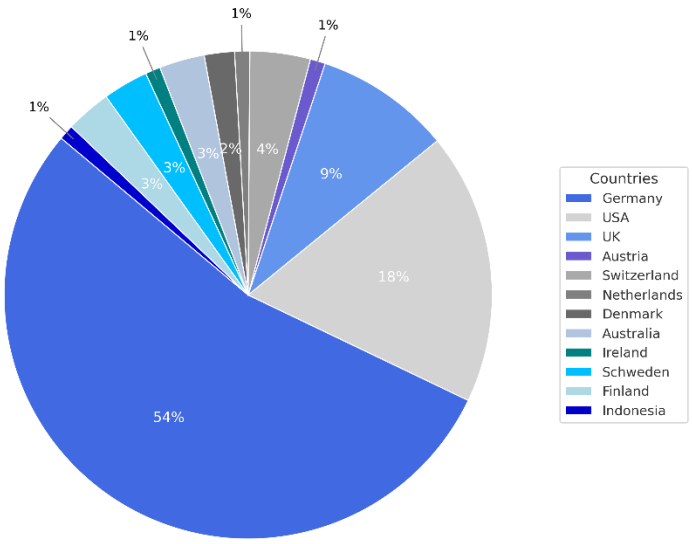

Fig 1. - VR/AR Project Sample

Barriers were observed based on project descriptions, reports, videos, and additional content about the projects. These were coded in a deductive thematic analysis (Boyatzis, 1998; Braun & Clarke, 2019), following the Steps presented in Figure 2. For the coding process, a category system of potential barriers was developed based on secondary literature on VR/AR integration in the public sector. Each category was defined and described with anchor examples and coding rules. The findings were consolidated and organized through the pre-defined category system. If findings were reoccurring, new subcodes on relevant topics were created on the basis of the defined categories. After conducting the deductive thematic analysis (Boyatzis, 1998; Naeem et al., 2023), we continued to explore potential application areas for chatbots within the projects and noted the potential of their integration in the given domain. We analyzed the potential of chatbots for public integration based on the proposed principles and fields of application presented by Cortes Cediél et al. (2023). We incorporated the proposed chatbot evaluation metric to highlight potential attributes that could be integrated into the list of projects.

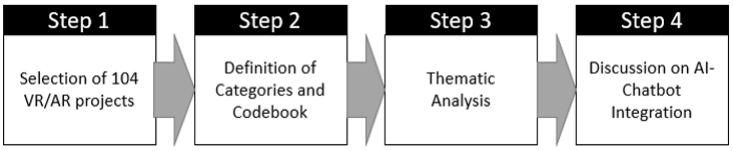

Fig 2. - Steps of the Thematic Analysis

To understand the current status of acceptance of VR/AR systems in public administrations, we rooted the analysis in theories of acceptance. The UTAUT model, as a modern and well-researched approach, involves the key aspects of performance expectancy, effort expectancy, social influence, and facilitating conditions, which lead to behavioral intention and use behavior. In regard to VR/AR adoption, users need to experience satisfaction based on their initial expectations of the system. Especially with immersive technologies like VR/AR, expectations may widely range. A totally immersive world may be expected, where the other one has no expectations (Xiong et al., 2024). Further, it needs to be mentioned that the UTAUT does not include an explanation of potential barriers that limit the acceptance of technology (Le Tan et al., 2024). Moreover, an individual's perspective is taken into account, while an organizational view is not prioritized (Ajibade, 2018). Barriers to the adoption of digital technologies stand in contrast to the adoption of a technology. In regard to VR/AR adoption in the public sector, well defined barriers are still missing to our knowledge (Vimal et al., 2023). Previous literature mentions the challenge to adopt VR/AR in the public sector (Lnenicka et al., 2024). The barriers in the public sector are versatile, which makes an evaluation of VR/AR technologies challenging. Nevertheless, to identify barriers regarding technology, the purpose and goal need to be taken into account. VR and AR are technologies that are well suited to educate vividly on different topics (Dwivedi et al., 2022). Le Tan et al. (2024) identified relevant barriers to VR/AR adoption in educational settings . They propose five central barriers from scientific literature: VR/AR adoption is affected by

infrastructure, technical issues, cost factors, complication, and human interaction. In this regard, VR/AR barriers in the public sector display similarities that warrant attention. VR/AR projects in the public sector demonstrate a strong focus on educational settings, with over 65% of the identified projects falling into this category. This includes public learning, but also education on public projects and cultural and historic settings, as for instance city tours and virtual art installations.

Infrastructure is highly relevant for the integration of innovative technologies (Dionisio et al., 2013; Lnenicka et al., 2024). Especially with the vision of an interconnected metaverse, infrastructure becomes a relevant indicator for VR/AR integration potential (Dwivedi et al., 2022). Public projects are already today integrated in internal services, support of urban planning, and e-participation (Ricoy-Casas, 2023). If a project manages to integrate existing data and information, the impact of this service increases in the eyes of the citizens (Frank et al., 2010). Existing public platforms, such as smartphones-apps and social networks, profit in the same way from an integration of VR/AR services. With regard to AI integration and the era of generative AI and technological advancements, infrastructure is a fundamental barrier to VR/AR systems and future adoption (Zuiderwijk et al., 2021).

Technical issues as barriers are a central problem for VR/AR adoption. These may result from technical limitations or immature implementations. Technical issues are the result of multiple factor problems and often strongly relate to the planning process and predicted goals for the system (Kumari & Polke, 2019). Regarding technical issues with VR/AR, it needs to be taken into account that already small flaws in the systems can highly affect the perception (Hsiao et al., 2024). In case of immature systems, users can experience technostress or cybersickness that affect the continuous use of a system (Souchet et al., 2023).

Avoiding unnecessary complexity is essential when quick results are valued (Lnenicka et al., 2024). As VR/AR projects often cope with unrealistic requirements, complication can arise without leading to observable value. Unnecessary complication may be the implementation of a VR system without a clear benefit in comparison to a 2D PC system (Stejskal et al., 2003). Also, complication can arise through nontechnical aspects in the project facilitation. Hence, inadequate communication of the service may lead to an awareness problem and ongoing complications with citizens.

Cost factors are relevant in the adoption process of a system. Innovative technologies can involve costs, which are not directly predictable (Naugolnova, 2024). Furthermore, the maintenance of these systems can create a quick overhead in comparison to the perceived reward. Some participants in public projects raised concerns about the impact of the technology and its complication (Teutenberg, 2025). Especially in learning settings, the results are not necessarily satisfactory. Further, the time cost factor should be considered while implementing these systems (Fegert et al., 2020).

The public sector needs to manage requirements from a variety of different users and stakeholders. Ease of use is not always guaranteed with public services (Chen & Aklikokou, 2020). Especially with technologies such as VR and AR, citizens need to be introduced on how to use and interact with a system. Usability can become a central barrier if not satisfactorily addressed (Kim et al., 2020). How effectively systems in public administrations address this topic is decisive for their further usage. Alongside usability, human interaction also becomes a relevant factor (Kim et al., 2020). As a technology that embodies users, VR is creating new normative rules and interaction patterns that influence how individuals perceive themselves and others within virtual environments.

3.2. AI-Chatbot Integration

The identified chatbot characteristics in the public sector by Cortés-Cediel et al. (2023) are used as a fundamental source for potential application fields. Cortés-Cediel et al. (2023) observed five principal purposes for chatbot integration: 1) searching for government information; 2) supporting access to government data; 3) providing public services; 4) improving citizen participation; and 5) facilitating communication between stakeholders. In regard to the identified barriers of VR/AR in the public sector, we outline how chatbots can be integrated with regard to these five principal purposes in public VR/AR applications. We propose solutions that could be implementable in the upcoming 3-10 years from the time of the given analysis due to technical advancements and innovation cycles in the public sector (Lnenicka et al., 2024; Stewart-Weeks & Kastelle, 2015). Data policies and individual country perspectives were not included, as the primary goal of the analysis is to highlight the potential of VR/AR and AI-chatbot integration in a divergent idea generation process without prematurely focusing on country-specific limitations.. We root the discussion on existing functionalities of chatbots and conversational agents and create an extensive perspective for the given problems in the public sector. Except for commercial services like ChatGPT, we analyzed multiple chatbot platforms for the public sector from private and governmental providers, including Botfriends, DialogBits, and the General Service Administration Chatbot. We analyzed these systems to extract a comprehensive picture of potential integration in VR/AR services.

4. Findings

The findings regarding barriers of current VR/ AR adoptions can be grouped into the five categories, namely infrastructure, technical issues, complication, cost factors, and human-interaction, as proposed by Le Tan et al. (2024). See Table 1 for a comprehensive overview.

Within the barrier of *infrastructure* three main problems could be identified from the sample set of VR/AR projects. Projects for firefighters or for police training, for instance, show promising applications to simulate critical situations in the job (e.g., project firefightervr). The project systems are mature and vividly present contents to the user. However, public administrations often set up cooperations with private IT-companies, which sell services to the public institutions. This can be problematic, as new content for the VR/AR systems is often not affordable or exceeds initial budget plans (Bonomi Savignon et al., 2024). A majority of the retrieved VR/AR projects did not actively proceed one year after release. Further, the education of administrative workers is a barrier, which limits the potential of VR/AR systems. IT experts are hard to recruit for the public sector (Haug et al., 2024). However, continuous maintenance of the VR/AR systems would be necessary to further develop and improve the contents. An additional challenge regarding infrastructure is the isolated setup of VR/AR services. Interfaces to existing infrastructure are rarely considered. So, projects that implement urban data, like the Ashbury Park Bike Lane Demonstration Project, are relying on a limited dataset. A continuous data-flow is nonexistent between external services and VR/AR systems. However, specifically projects aiming to boost efficiency require an accurate, precise, and current dataflow. The lack of real-time data decreases the quality of simulations and analyses. Thus, the continuous data updates are a highly relevant aspect for Digital Twin integration. For instance, the Hamburg port authority set up a promising project that integrates a continuous data stream from the port to the Digital Twin in the virtual environment, enabling real-time simulations (Hamburg Port Authority [Hg], 2025). This example indicates that an integration of urban data in VR and AR is already possible and that the incorporation into existing systems can be beneficial to allow data exchange. However, the majority of projects do not implement an API or interface to existing urban data sources. VR/AR infrastructure problems often root in design issues rather than implementation (Creed et al., 2024). Critical are limited standardizations, such as complicated devices or a limited scope of application. A variety of AR city tour apps were integrated in many different towns in Germany. The towns (e.g., Bergen-Belsen, Chemnitz, or Munich) developed their own system with individual functionalities. Furthermore, low-code tools, which allow the development of applications for the public, are not frequently applied (e.g., ARget). A common infrastructure of applications in general could condense the potential of the technologies and allow the exchange of knowledge and resources. For instance, 3D-models that are used in one project may also be applicable in an AR communication app in a different project. A shared technological infrastructure, including databases and APIs, sets the foundation (Creed et al., 2024). Barriers in project infrastructure sometimes were already rooted in the project design. For instance, the Ashbury Park Bike lane project, initially created to gather data on the usefulness of a new bike lane, lacked a control condition or site; thus, the infrastructural design flaw led to inconclusive results.

Tab. 1- VR/AR Integration Barriers in the Public Sector

Infrastructure	**Technical Issues**	**Complication**	**Cost Factors**	**Human Interaction**
1a) Difficulties finding schooled personnel	1b) Issues with system stability	1c) Unclear outlines of project necessities and value propositions	1d) Projects dependent on external funding	1e) Barriers of usability
2a) Introduction of isolated systems rather than incorporation into existing systems	2b) Necessities for additional equipment and sensors	2c) Insufficient communications to target audience	2d) High time-effort for setup and maintenance	2e) Demographic differences in interaction
3a) Infrastructural issues often rooted in the project design prior to implementation	3b) Difficulties with intuitive interaction and model quality	3c) Permanent relevance not ensured		3e) The dangers of over-gamification
	4b) Incomparability of data due to variations in quality			4e) Limiting negative effects
				5e) Difficulties with task alignment

A major *technical issue* in VR/AR projects is the stability of the systems. Especially in complex experimental settings with collaborative VR or with real-time rendering (e.g. Vision 5.G or FX Reality), systems tend to be still immature. Further, in some cases additional equipment is necessary, which can affect the motivation of the citizens and public target groups. Specifically simulators for medical or police training often involve heavy and complex tools, which reduces the scalability of these projects and requires additional testing (e.g., virtual extinguishing trainer). Moreover, latencies are still a major issue, which needs to be addressed (see project Telemedicine in the emergency services). Another factor often not sufficiently explored prior to implementation are barriers with quality and fidelity of the presented 3D-models. Depending on the field of usage, reduced quality can significantly impact the overall usefulness of the application (e.g. Pixplorer). Within the projects, complex 3D models were often taken as self-explanatory (e.g. HoloPLANNING). However, given that 3D models are the primary means of visualization in these systems, a clear definition and standardization of model requirements would enhance usability. In conclusion, the technical complexity of VR/AR projects varies widely, from high-end 5G-based implementations (e.g., Vision 5.G) to low-cost AR tools (e.g., ARget), making their technological maturity difficult to compare directly.

Based on the projects investigated, no direct conclusions could be drawn regarding costs or *financial stability*. However, many services appear to be highly dependent on external third-party funding (e.g., from the German Ministry of Education and Research).
Beyond financial stability, the time and effort required to set up and maintain these systems is considerable. Furthermore, due to the lack of reliable user data, it is important to emphasize that, at the time of this research, most VR/AR projects remain in an experimental phase and do not yet offer financially sustainable services capable of driving rapid transformation in the public sector IT landscape.

In the VR/AR-projects an overhead of *complications* are observable. VR and AR are complex technologies, which require well defined use-cases and a clear value-proposition (Kim & Hall, 2019; Pedersen, 2024). These technologies are often implemented in cases where a need for immersive visualization does not necessarily exist, or is not outlined sufficiently (e.g., Conflict Handling Ambulance Syd). Many public VR/AR projects are not sufficiently communicated to its audience and therefore endangered to not permanently be relevant (e.g. ARget). Furthermore, permanent relevance can be a barrier in project fields that are regularly subject to scientific advances (e.g. medical tr.AI.ning or OP der Zukunft, eng. OR of the future).

In relation to *human-computer interaction*, a few aspects may limit the interaction between citizens and administration. Primarily some services are described to have low perceived usability. For instance, in the project AR/VR.NRW figments, an open-source content creator tool, was developed to set up virtual environments for learning and teaching. In the project it was noticed that VR is not necessarily a better tool for communication of learning contents than a standard PC version: “With regard to self-assessed learning success, no significant advantage of the VR group over Desktop could be identified” (Müser et al., 2023).

A second point that administrations need to be aware of is the interaction with critical target groups. Some projects (e.g., SenopiVR) work with elderly, disabled, or dementia-affected people. Except for demographic states, the individual levels could also be considered. An application in historic settings could be addressed for different educational levels and personal preferences (e.g., Chemnitz.Zeitweise, eng. ChemnitzTimewise). Each target group needs special communication and treatment (Bruno & Muzzupappa, 2010). VR/AR often inherits gamification aspects that need to be aligned. Gamification can be an engaging factor; nevertheless, gamification can also reduce attention when not securely applied and adjusted to the educational level (Dicheva et al., 2015). Additionally, it needs to be taken into consideration that gamification can induce stressful and uncomfortable situations. Simulations in critical situations, such as police treatments, or training for firefighters should be limited to their target audience to not traumatize inexperienced users (e.g., projects Ambulance Syd and firefightervr). VR/AR applications in the public sector often have just one communication goal, which is communicated. Information is provided mainly to one target group. However, public processes, such as participatory initiatives, involve multiple target groups that play a significant role. A setup of multiple VR and AR views would address this problem and align knowledge states. Also, the experience in VR and AR is important to fulfill the potential of the applications. Especially avatars and interaction partners need to be aligned to the task. Here it is extremely important to mention that the right degree of abstraction and presentation is essential to create a satisfying presentation and relation (Commonwealth of Pennsylvania, 2025).

5. Discussion

From a long- and short-term perspective AI-chatbots can be relevant to improve current VR/AR-applications in multiple fields. Before possible integrations are presented, we would like to note that the proposed concepts are not filtered on cost-efficiency and maturity level. The proposed applications of chatbots address primary the identified barriers and highlight potential synergies.

Infrastructure Barriers: AI-chatbots may help in the upcoming years to reduce the dependency of private IT

providers with VR/AR services. AI-powered low-code environments could be useful to reduce the number of external providers through AI-services. Already today advanced conversational agents and chatbots are able to provide content based on a given prompt of a user. For instance, AI-driven 3D agents, which produce VR/AR models based on a given prompt like e.g. Shutterstock Generative-AI. In comparison with the public low-code platforms in the administrations (e.g. ARget or VRpigments), public integration could improve flexibility and generalizability. Dependency problems from external partners would not vanish, however the number of VR/AR IT-service providers could be reduced, as more functionalities could be implemented with the assistance of an AI chatbot. Also, the maintenance problems would fade away, as the chatbot could enable to generate new content without the need for external maintenance. AI-chatbots are often able to learn, which could help to improve VR/AR-services over time. The core functionalities would improve constantly without the need for updates after the end of potential funding. Apart from core functionalities, a chatbot could provide quick data analysis on top of the existing data-streams and visualizations (Alaaeldin et al., 2021). For instance, in digital twin projects, such as the Hamburg Port Digital Twin, a chatbot in the virtual environment could provide additional information on visualized data-streams and highlight critical points in the virtual environment. A chatbot would also allow new interaction techniques in the VR/AR-environments, as it may interact with the user by verbal communication. As typing is not a reliable option in VR/AR, voicebots could be an alternative (Hwang et al., 2024). A chatbot does not necessarily require integrated data operations. However, advanced chatbot systems provided by external vendors may include limited data analytics functionalities. For complex requests, an API driven chatbot could be an optimal solution. This type of solution only handles requests with a language NLU and forwards the contents to an external service provider (data-warehouse, BI-platform) (Adamopoulou & Moussiades, 2020).

Technical Stability: The quality of VR/AR projects is critical. AI-chatbots and agents could be used for optimization and quality control in VR/AR projects. A chatbot could serve as a guide during the implementation process, for instance within low-code applications (e.g., ARget). Public employees could then streamline development processes of future applications (Kumar et al., 2024). The chatbot could engage with the employee and give guidance either in a content management interface or integrated in the virtual environment as a virtual avatar. If problems occur in the development process, the chatbot could also work as an advanced developer console, which gives hints on development issues, or makes suggestions for given coding problems (Simão de Deus & Barbosa, 2024).

Cost-factors & Complications: As an additional functionality, chatbots do not resolve the financial challenges of current VR/AR projects. However, given the growing demand for chatbots in public websites and services, integrating VR/AR functionalities into chatbot systems could enhance the visibility, flexibility, and user guidance of existing applications

Human Computer Interaction: Chatbots can provide guidance in VR/AR-applications and allow to streamline interactions. Possible application fields are citizen participation, facilitation of communication between stakeholders, provision of public services and presentation of government data (Cortés-Cediel et al., 2023). Especially for different demographic groups, chatbots could provide assistance in VR/AR-applications. Based on this, flexible interaction techniques could be enabled through a chatbot that processes spoken information and transforms it into meaningful content. One possible application would be a chatbot acting as a virtual tour guide in interactive experiences, answering questions, providing guidance, or engaging in storytelling. Moreover, AI-chatbot collaboration represents a novel form of interaction that could enhance the liveliness and responsiveness of VR and AR environments. Particularly, AI-driven avatars used for onboarding processes (e.g. in firefighter training scenarios) could help personalize the experience (Luo et al., 2024). In this context, the perceived similarity of the chatbot may foster closer interaction between users and administrative systems.

Chatbots can serve as a powerful tool to address barriers encountered by current applications and to reshape the landscape of VR/AR service systems. In particular, chatbots help streamline existing applications and communicate their functionality in a more flexible and personalized manner. However, it remains debatable whether AI-driven chatbot integration and the incorporation of chatbot personality are essential, or whether the provision of information could be sufficiently handled by standard text interfaces or simple rule-based logic. With technological advancements such as the emergence of Generative AI, the introduction of intelligent, AI-driven chatbots in the public sector appears to be a matter of time. Nonetheless, considering current technological limitations, it may take several more years before the public sector reaches a level of maturity where both technologies, VR/AR and chatbots, can develop meaningful synergies. It is worth emphasizing that VR/AR and chatbot projects should ideally be designed in close alignment. These technologies complement each other through combining visual, auditory, and textual elements. For the VR/AR projects analyzed in this study, chatbot integration may pose a challenge, as the systems are often deeply embedded within their own ecosystems and databases. Establishing a reliable and unified network infrastructure is a crucial prerequisite for unlocking the full potential of a combined VR/AR and chatbot solution.

6. Conclusions

This study examined the current state of VR/AR applications in the public sector, with a particular focus on barriers, potential use cases, and technological synergies. Special attention was given to AI-powered chatbots as a complementary technology that may enhance usability, accessibility, and human–computer interaction. Against this backdrop, two central research questions were addressed: (1) What are the current barriers to VR/AR adoption in the public sector? and (2) How can AI-powered chatbots contribute to overcoming these barriers? A thematic analysis of 104 public sector VR/AR projects was conducted, highlighting four key challenge areas: infrastructure, technical limitations, system complexity, and human-centered design.

The analysis revealed several recurring challenges. Many systems are dependent on private IT providers, which reduces autonomy and increases long-term vulnerability. High maintenance requirements and a lack of standardization have led to a fragmented ecosystem of incompatible platforms and services. System stability, positioning accuracy, and hardware requirements remain problematic. Core components such as 3D models often fall short of application-specific demands in terms of quality and clarity. In addition, the absence of established design patterns hinders the scalability and usability of these systems. Financial sustainability poses another critical issue, as most projects rely on temporary external funding. In many cases, the complexity of the solutions outweighs their practical value, making their unique selling points difficult to identify or justify in comparison to conventional approaches.

In regard to chatbot applications, the study explored several promising use cases aligned with the barriers identified. Chatbots show potential in enhancing interaction with VR/AR systems by simplifying navigation, providing guidance, and personalizing experiences. However, their integration is more feasible in high-quality systems with substantial data communication. It remains questionable whether low-budget implementations would benefit equally. The analysis also suggests that AI chatbots could assume administrative roles in immersive environments, acting as tutors, assistants, or digital workforce elements. In particular, AI-driven avatars functioning as public companions present a compelling area for future exploration.

This study has certain limitations that should be acknowledged. Primarily, the analysis is based on a dataset of 104 VR/AR projects, which, while supported by secondary literature, cannot be considered representative. Thus, while the findings provide meaningful insights, they are to be understood as an initial foundation for further empirical and design-oriented research.

Looking ahead, the convergence of chatbot and VR/AR technologies opens up promising interdisciplinary fields. As chatbot functionalities become increasingly compatible with immersive systems, the boundaries between modalities—visual, auditory, and textual—begin to dissolve. This intersection calls for the development of new design patterns tailored to hybrid applications in the public sector. Exploring these frontiers may significantly shape the future of digital public services and user engagement.

Abstract. This paper addresses a gap in the AI governance literature in understanding collaboration between national governments and tribal nations in governing AI systems for emergency management. This conceptual work develops and presents a governance design framework for accountable AI systems to fill the knowledge gap by drawing from the fields of public administration, information systems, indigenous studies, and emergency management. This framework situates the governance framework in a cross-sovereignty historical, legal, and policy contexts. It captures the multi-level features and embeddedness of governance structures, including the levels of collaborative governance structure, software system governance rules, and technical software system design. The focal governance dynamics involve the collaborative process in the bi-directional relationship between governance rules and technical design for accountability and the feedback loop. The framework highlights the importance of multi-level and process considerations in designing accountable AI systems. Productive future research avenues include empirical investigation and resulting refinement of the framework and analytical rigor employing institutional grammar.

Keywords. Collaborative governance, AI systems, governance design, tribal nations, socio-technical systems, AI chatbots
Research paper, DOI: https://doi.org/10.59490/dgo.2025.980

1. Introduction

The governance of artificial intelligence (AI) for public value creation is both a significant challenge and forward-looking opportunity for digital government. AI affords capabilities in finding patterns and making predictions by leveraging numeric, text, and image data to improve public policy and administration. However, the data-driven AI algorithm also tends to magnify and worsen the biases and errors existed in the data (Wirtz et al., 2020; Young et al., 2021). Such biases tend to disproportionately impact marginalized populations such as indigenous people that are not appropriately represented in the digital data sphere. The forward-looking opportunity lies in the design and implementation of a governance framework that proactively minimizes the harm and optimize public value creation.

The current literature on the governance of AI has provided governance options and frameworks (Chen et al., 2023; Wirtz et al., 2022; Young et al., 2019). Governance solutions span from within a particular governance agency, to national AI governance arrangement, and to a regional or global governance rules for responsible AI. EU AI Act passed in 2024 is an example of managing the risks of AI. Industry self-governance has been promoted by major international corporations as a governance option. The academic scholarship has provided governance frameworks that address the unique features of public administration (Chen et al., 2023; Gasco-Hernandez et al.,

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

2022; Ruijer, 2021; Wirtz et al., 2022; Young et al., 2019). One such framework is the four-layered and integrative AI governance framework, inclusive of risks, risk management, guidelines, and governance layers, that aims for risk management (Wirtz et al., 2022).

However, the knowledge gap of AI governance exists in several crucial areas as related to public value creation and salient issues facing our society. First, the governance of AI in cross-sovereignty context as related to marginalized tribal nations and indigenous communities is under-addressed. Second, there is a gap in fully addressing the complexity of the interactions between the social system and technical systems for effective governance of technologies such as AI. Lastly, the literature has opportunities to grow in governance of AI in addressing emergency management as a growing public service area.

This paper aims to provide a governance framework to address the three aforementioned areas of knowledge gap. This framework focuses the cross-sovereignty context of national government working with tribal nations while recognizing the legal and policy framework governing the design and implementation of AI systems. It takes an integrative and interdisciplinary approach to analyze the socio-technical system while recognizing the embeddedness of rules and processes at multiple levels. This paper focuses on the AI chatbots for emergency management to address the salient issues of EM in the wake of rising natural and manmade disasters. For public value creation, this paper selects accountability as an important public value recognized by both software and public administration scholars and encompassing other public values.

Section 2 provides the specifics on the cross-sovereignty context, accountability, AI systems, and emergency management to pinpoint the contribution of the proposed framework to the larger literature. Section 3 develops and describes the proposed multi-level collaborative cross-sovereignty governance framework grounded in the supporting literature and practice. This section constitutes the majority of the paper length. Section 4 provides a summary of the work and point to future research.

2. Context, Accountability, AI System Design, and Emergency Management

2.1 The Socio-Technical and Cross-Sovereignty Context

The broad socio-technical context includes biological and physical attributes, natural and man-made resources, data, technology, policy and legal frameworks, rules at the constitutional and collective action levels, political and power relationships, socioeconomic and cultural characteristics, and history of collaboration and conflicts (Chen & Lee, 2018; Emerson & Nabatchi, 2015a; Ostrom, 2010). Biological and physical attributes are essential for understanding the bio-physical context of public service challenges such as disaster recovery (Ostrom, 2010). The state of and need for data and technology are essential for digital governance across boundaries (Chen & Lee, 2018a). Data and technology elements relevant to the context are particularly salient for the development and implementation of information systems in tribal nations facing the challenge of limited internet accessibility and digital infrastructure (Intahchomphoo, 2018). Rules at the constitutional and collective action levels reflect the formal policy and legal requirements and the informal cultures and power relationships.

A cross-sovereignty context requires attending to both formal and informal aspects of collaboration. The history of conflicts and collaboration is another salient contextual element for collaborative governance. An important historical context is the harm U.S. federal government policies have inflicted on indigenous people, such as through the Indian Removal Act in 1830, which removed Indian tribes from their original lands, and the Dawes Act in 1887, which sent children in Indian tribes to boarding schools.

Such cross-sovereignty context increases the heterogeneity and complexity of governing and designing software systems. From the beginning, tribal nations have held land and their own form of governance, as determined in the Supreme Court cases of Cherokee Nation v. Georgia, 30 the U.S. 5 Pet. 1 (1831), and Worcester v. Georgia, 31 the U.S. 515 (1832) at 516. The complexity of governance grew after the passage of the Wheeler-Howard Act in 1934, also known as the Indian Reorganization Act. This Act created tribal governments that replicated the U.S. form of governance, complete with an executive branch, legislative branch, and judiciary. Today, this often translates to a tribal chairman, tribal councils, and court systems. This Act also created Constitutions written by the individual tribes, with their own laws, police, and set of procedures. Moreover, there is heterogeneity in the capacity, population, land area, and governance structure among tribes. There are 574 federally recognized Indian tribes 87 FR 4636 (United States Bureau of Indian Affairs, 2022). The Census Bureau's data on the American Indian and Alaska Native populations reveals the diversity of population sizes. Reservations can range from the 15-million-acre Navajo reservation in Arizona to the 1.32 acre Likely Rancheria of the Pit River Tribe in California (Tiller & Harris, 2015). Each reservation has its own government and governance structure and process that blend U.S. and tribal elements.

Explicit recognition and consideration of tribal sovereignty is essential for effective inter-governmental collaboration between the U.S. government and tribal nations (Quick, 2021). There is an urgency to address the

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

challenges of climate change and environmental stewardship that do not comply with jurisdictional boundaries (Kettl, 2006). The experiences in inter-governmental collaboration involving tribal nations suggest the importance of recognizing and protecting boundaries rather than dissolving them (Quick & Feldman, 2014). Mutual consent among sovereign entities is necessary. Sovereignty necessitates proper tribal consultation to facilitate inter-governmental collaboration (Quick, 2021).

2.2 Accountability and Its Assessment

Accountability is a core concept of public administration (Koppell, 2005) and a significant public value to enable the advancement of other public values (Nabatchi, 2018). Some people in the computer science community also recognize the importance of holding software systems accountable for the core values held by our society such as privacy and security (Feigenbaum et al., 2011). On a basic level, accountability is about holding an organization or individual to be responsible for its actions (Lampson, 2005). Some actors (either organizations or individuals) have the right to hold other actors to a set of responsibility standards, judge the fulfilment of these standards, and to impose sanctions for not meeting these standards (Grant & Keohane, 2005, p. 29). Although contexts and conceptualizations of accountability differ, the organizing question is who is accountable to whom and for what.

This paper takes an inclusive approach to accountability for public policy and administration by defining it as the achievement of policy objectives. This paper extends policy objectives to intermediate ones, including the development of technical and governance capacities needed for achieving the final policy objectives. The process capabilities are critical conditions for achieving policy goals (Overman & Schillemans, 2022). A design of effective collaborative process across organizations and jurisdictions constitutes a process capability.

Moreover, this paper incorporates the varying assessments by key stakeholders representing different sovereign entities and the people impacted. Stakeholder bodies include, but not limited to, governmental agencies, professional associations, civil society organizations, client representation groups, and interest groups (Brummel, 2025). The perspective and focus of a particular group of stakeholders can impact the assessment of goal attainment. For instance, the U.S. federal government probably focuses on what is prescribed by federal laws and regulations for their collective interactions with tribal nations. Tribal nations tend to focus on their unique conditions and needs. The proposed framework's inclusive approach allows for multiple assessments of accountability depending on the stakeholder in question. Moreover, the involvement of a variety of stakeholders brings the benefits of multiple perspectives, including control, institutional, managerial, learning, and reputational (Brummel, 2025).

2.3 Interdisciplinary and Integrative Design

This paper aims to develop a preliminary framework of collaborative governance of information systems for public service across sovereign entities. This framework integrates insights from collaborative governance by Emerson and Nabatchi (2015a, 2015b), institutional analysis and development by Ostrom and colleagues (Ostrom, 2010; Ostrom et al., 1994), and digital governance by Chen and Lee (Chen & Lee, 2018). Our framework first recognizes sovereign nations and the U.S. governments as autonomous entities entering a collaborative arrangement. Such recognition serves as the political and institutional basis for collaboration (Emerson & Nabatchi, 2015a). The recognition of autonomy in decision-making aligns with the self-determination and sovereignty of tribal nations.

This framework also integrates insights from human-computer interaction (HCI) research with an emphasis on working with indigenous people. Successful intercultural HCI design goes beyond a typical design process by considering different mentalities, thought patterns, and problem-solving strategies unique to different cultures (Abdelnour-Nocera et al., 2013). It is important to acknowledge local epistemologies in HCI research and prioritize values such as harmony and humanness in community-based interactions. One main challenge facing HCI design involving indigenous people is that information dissimilarities may arise from a knowledge mismatch between indigenous participants and researchers (Parsons et al., 2016). Participatory design empowers indigenous members as co-participants to enhance the understanding and application of indigenous knowledge and practices. For example, storytelling and reflection are more appropriate ways of knowledge sharing with indigenous people (Ostashewski et al., 2020).

The development of this framework advances the knowledge about governance design by following the guidelines for applying design science in public administration (Meijer, 2024). The focus of this paper is on governance design. The considerations of methodological guidelines such as studying causal mechanisms, understanding the distinctive impacts of context and design intervention, and addressing the interactive effect of design and context. The proposed framework also shares the goal of moving from the specific cases to generic knowledge (Meijer, 2024) and adds the multi-level and dynamic nature of governance design and outcomes.

2.4 Emergency Management (EM) and EM Technologies

This study focuses on emergency management as a critical area of knowledge advancement in the face of more

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

frequent and larger scale climate-related disaster events such as wildfire, hurricane, flood, etc. An effective approach to emergency management requires a life-cycle approach, including phases of emergency management as defined by the U.S. Federal Emergency Management Agency include preparedness, mitigation, response, and recovery. Collaboration among organizations and individuals in the public, private, and nonprofit sectors is critical for leveraging people and resources needed to respond and recover from an emergency, as defined by FEMA as the whole community approach. Moreover, a cross-jurisdiction coordination and collaboration are equally important as those disasters impact multiple jurisdictions (Kettl, 2006).

Emergency management is even more critical because of the magnified vulnerability experienced by indigenous communities on tribal lands. The impact of climate change hits the indigenous communities particularly hard because of being pushed to move to the marginalized land by the colonizers (Flavelle & Goodluck, 2021). The lack of federal recognition needed for financial assistance for some indigenous tribes exacerbates the recovery challenge (Chavez, 2021). A vast majority of indigenous tribes has only limited financial and human resources for emergency management.

Technologies play an important role in effective emergency management. There are a variety of communication technologies such as social media, web-based EOC, mass notification software programs deployed to facilitate notification of an emergency and coordination of disaster responses (Chen et al., 2024). Technologies can also support decision-making at an emergency operation center by creating a common operating picture to coordinate organizations and individuals to facilitate timely and coordinated responses (Kapucu, 2006).

The recent developments of AI afford the opportunity to process incident-related information from a variety of sources and conduct real-time translation for community-members speaking different languages. Moreover, AI can facilitate the reporting of emergency situation or damage via chats. For instance, AI chatbot can serve as an emergency reporter for the tribal members (Tsai et al., 2023).

3. A Multi-level Collaborative Cross-sovereignty Governance framework for Software System Accountability for Emergency Management

3.1 Governance Design: An Institutional Approach

The governance framework adapts pertinent rules from institutional design (Ostrom, 2010; Ostrom et al., 1994) to model the governance structure of a sociotechnical system for software design. First, participant rules prescribe who can participate in various positions and decisions. For a software system regarding tribal affairs, a participant rule can require someone to be a tribal member to participate in the design. Second, position rules specify the positions that participants can take in the governance structure. At the system design governance level, one position can be policymakers, who decide whether to adopt a certain software system for the entire tribe. Another position is the software co-designer. The third type is authority rules, which prescribe a set of decisions attached to a position. For instance, a software developer has the authority to make technical decisions on the choice of the software development environment. The fourth type is information rules, which prescribe what information is available to each position and decision. For instance, an information rule can allow tribal leadership council members to have full access to the software system development history and system specifications for making the decision on tribe-wide adoption of the system. The payoff rules specify how benefits and costs are allocated to a participant in a specific position. For instance, a tribal member may be a software system user who can use the system for free. This framework utilizes these rules to model the governance structure.

The application of this framework will utilize typology and the specifics of rules to model the governance structure. The governance structure includes the specifics of each type of rules and their configuration. Rule configuration is important to understanding the governance structure and its impact on outcomes (Ostrom, 2010). Moreover, attention will be paid to the rules-in-use, which reflect practice better than the rules in the book. Rules-in-use structure the actual behavior of the participants taking on various positions and making decisions. Thus, some of the empirical work proposed by this project is understanding the rules-in-use.

3.2 Multi-level Governance Structure and Embeddedness for Emergency Management

The sociotechnical system of software system design has three levels within the legal and policy framework for cross-sovereignty relations as seen within the dotted box in Figure 1. The “collaborative governance structure” level includes the laws and policies that structure the interaction between FEMA and tribal nations for emergency management. Tribes typically go through the states where they have land to declare disasters and receive funds from FEMA. Post Hurricane Sandy in 2012, the Federal Government started the Pilot Program, wherein tribes could declare disasters and directly petition on the federal level for funding and help. This process requires a Tribal Chief Executive to declare a disaster after an event has occurred. At that time, the Tribe’s Emergency Plan should be activated (Robert T. Stafford Disaster Relief and Emergency Assistance Act, 1988). An Initial Damage Assessment should be conducted. The disaster event should be of such severity and magnitude that it is beyond the ability of

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

the tribal government to respond (Federal Emergency Management Agency, 2017). The Initial Damage Assessment requires teams to collect data, travel to the affected areas, and conduct appropriate research on the matter. From there, a Joint Preliminary Damage Assessment is completed by FEMA to substantiate the Initial Damage Assessment. Damages should amount to a minimum of $250,000.00. All this must be done within a 30-day period.

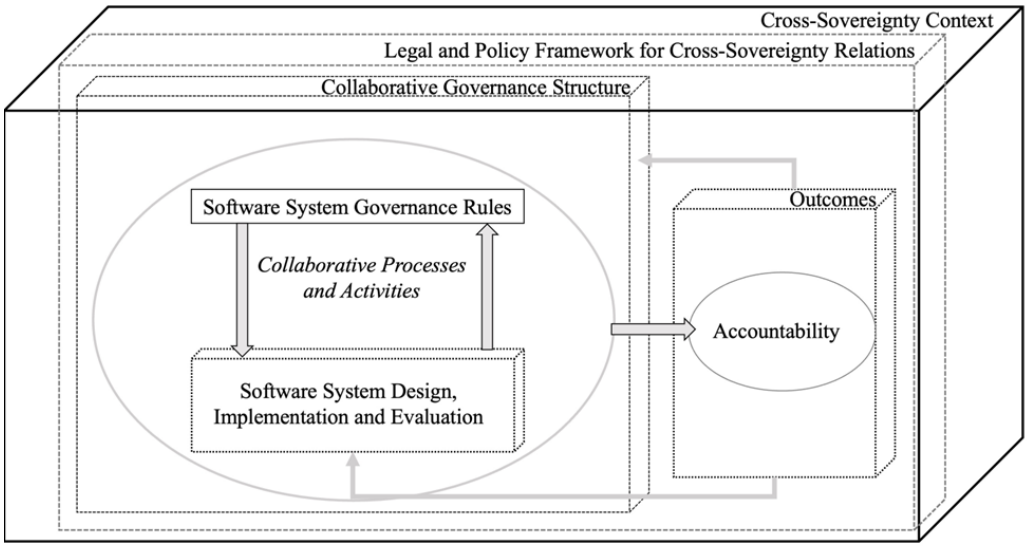

Fig. 1 - Multi-level Collaborative Design Framework for Cross-Sovereignty Software Accountability.

At the level of software system governance as illustrated as the top box inside the oval, there are rules prescribing the design and implementation of software systems across sovereign entities. Participant rules for participatory design can allow tribal members and the FEMA tribal liaison to participate as co-designers of the software system. Position rules prescribe various roles that participants can assume, such as tribal council members, software system designer, and software system users. Authority rules dictate what a position, such as a software system co-designer, can choose to do. For example, a software system co-designer may choose to decide on the features or express feature preferences. Information rules determine what information is available to various positions. For example, software system users may not have access to specific cost and revenue information about the system. The payoff rules specify how benefits and costs are allocated to a participant in a specific position. At this level, the payoff rules specify how the costs and benefits are distributed across users, designers, council leaders, and FEMA officers. Rule configuration and rules-in-use better reflect the reality of the governance structure at this level.

The third level is the technical design of software systems as illustrated as the bottom box inside the oval. The technical design operates within the rules governing participation, positions, authority, information, and payoffs at the system governance level. At this level, the decisions are more technical in nature. Such technical decisions include those on data, information architecture, server, telecommunication networks, and human-computer interface. Such technical design is likely to span across the design, implementation, and validation phases of a prototype.

These decisions at the level of technical software design are embedded in the software system governance level. Rules at the system governance level prescribe the roles, authority, and interactions between people assuming various positions. These rules are further embedded in the level of laws and policies that prescribe the parameters and boundaries within which the rules at the system governance level are legitimate. The base level of the sociotechnical system, such as laws and policies governing cross-sovereign relations, is the most difficult level to change. Such a change requires negotiation between sovereign entities and approval from their respective legislative bodies. The rules at the software system governance level are easier to change than those at the base level. The technical decisions made throughout a software system lifecycle are the easiest of the three levels to modify. Technical rationality is the main basis for justifying decisions. The relative difficulties of changing these levels have implications for the feasibility of recommendations targeting a specific level and for the dynamics of change connecting various levels.

3.3 Processes, Activities, and Dynamics of the Governance Framework

Several processes are essential for effective collaborative governance. These include building trust and shared understanding, cultivating institutions and the capacity for joint action, managing interdependence and motivation, and developing the technical capacity for collaboration (Chen & Lee, 2018; Emerson & Nabatchi, 2015a). Trust building is essential for addressing historical distrust between tribal nations and the U.S. government, which is a

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

barrier to collaboration (Quick, 2021). Furthermore, it is important to have a shared understanding of the goals of the collaboration and incentives for participation (Ansell & Gash, 2008). Joint actions between the U.S. government and tribal nations require guiding principles for collaboration and coordination, such as reciprocity and respect for sovereignty. Effectively managed interdependence provides the needed payoffs for motivating each participating organization to contribute to collaborative efforts. Tribal nations typically depend on the U.S. government's financial assistance in disaster recovery, especially for any damage to their infrastructure. Technological capacity is needed for cross-boundary coordination and collaboration, especially for a sociotechnical system spanning organizations (Chen et al., 2021; Chen & Lee, 2018). Such technical capacity can be a centralized information system used to organize and produce collaborative services.

Collaborative governance processes are used to achieve the intended outcomes. The outcomes for collaborative governance include productivity outcomes, such as effectiveness in achieving policy goals, and process outcomes, such as sustainability of the collaborative process (Emerson & Nabatchi, 2015b). Outcomes can be measured at the level of individual participating organizations or of the collaborative (Emerson & Nabatchi, 2015b; Provan & Milward, 2001). There can also be personal-level outcomes for individual participants. Moreover, these outcomes influence the adaptation of the system context and collaborative governance structures and processes (Emerson & Nabatchi, 2015a). An understanding of these influences over time provides insights into the feedback loops and evolution of the system.

A process framework for accountable AI-enabled systems involves the entire lifecycle of the service goal-setting, system development, service impact, and evaluation (Chen & Ahn, 2022). Participation of key stakeholders when implementing AI systems in the public sector is critical for achieving public values such as efficiency, effectiveness, and accountability. One governance solution is the participation of impacted groups, especially in the phase of goal-setting and evaluation of the impact of AI systems. Facilitative leadership for cross-boundary collaboration in aligning the goals and objectives of participating organizations is likely to be helpful for algorithmic accountability (Mikhaylov et al., 2018). Transparency is also an important element in achieving AI system accountability (Chen & Ahn, 2022). AI systems present new challenges related to transparency that are distinctive from other software systems. The machine learning of model development and refinement introduces opaqueness in system development. A solution to the opaqueness of AI systems that increases transparency is explainable AI that is considered an effective governance solution (Coglianese & Lehr, 2019; König & Wenzelburger, 2020). During the final phase of the lifecycle, it is important to have transparency on the specific impacts of AI systems on each stakeholder group. A process mechanism needs to be in place to ensure transparency from goal-setting to impact evaluation and thus achieve accountability (Chen & Ahn, 2022).

3.4 The Bi-Directional Structure and Processes of Accountable Cross-Sovereignty Smart Chatbot Design

This paper focuses on AI chatbots as a type of AI-enabled software system due to their relevance to a cross-sovereignty context involving tribal community members and their adaptability to a diversity of user capabilities and preferences. AI chatbots are AI-enabled systems that provide interactive, personalized assistance in accomplishing a particular task. The tasks can include finding relevant service information and submitting a service request. The conversational capability of smart chatbots fits the oral tradition of tribal communities, as the chatbots and these traditions use conversations to interact, learn, and organize. Smart chatbots with natural language processing capabilities also allow for voice inputs. Moreover, AI chatbots can adapt to user capabilities and preferences. The capability of both text and voice options on mobile phones supports a variety of user capabilities and preferences. Moreover, a smart chatbot can also personalize the information and support depending on the knowledge and needs of the users.

This section focuses on the bi-directional relationships between the software system governance level and the technical software design level, as illustrated within the oval in Figure 1. The software system governance level prescribes the goals, structure, and processes for the technical software level. The goals of an AI chatbot are to ensure public values such as efficiency, effectiveness, and equity (Chen & Ahn, 2022). These goals are also the basis for the performance metrics assessing process and productivity outcomes. The governance level also dictates the management of financial, human, and material resources for the AI system. The governance-level decisions impact the technical system design level by prescribing which organizations are eligible to participate, what positions are available, what authority is associated with each position, what information is available to what position, and the distribution of costs and benefits across organizational boundaries. A salient aspect of the governance level decision is determining the tribal office and U.S. government offices that are legitimate governmental participants in the cross-sovereignty collaboration.

The results of the decisions at the technical design level serve as important information feedback for the decisions made at the governance level. These technical decisions include how the design addresses use cases and user characteristics. These characteristics include efficacy in using technology, trust in technology, subject literacy, and system-specific familiarity and understanding. In addition, these decisions determine the data used, algorithm development, and the selection of a service platform. The performance of these technical decisions provides the

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

needed information for decisions made at the governance level. The performance information can cover the frequency and duration of using AI systems and the extent and quality of the service rendered by the AI system. The information on the practice and behavior of the technical design can be useful for understanding the alignment between prescribed rules and actual behavior.

These bi-directional relationships between the two levels and their joint results become important information feedback for the base level of the sociotechnical system for software design, namely the relations between sovereign entities. The sovereign entities, in this case, the U.S. and tribal governments, can review these bi-directional relationships and collective outcomes. In so doing, they can decide which government or governmental office is a legitimate entity for formulating system governance rules to ensure accountability of the software system to its stakeholders.

Collaborative governance activities shape the bi-directional relationships at the system governance level and system technical design level and their collective impact. Leadership activity can foster shared understanding across sovereign entities and motivation for collaboration. Another main area of activity is cultivating the rules for promoting cross-sovereign collaboration at the system governance level and the technical design level. The development of technical capacity for joint action facilitates coordination among participants across sovereign entities. Collectively, these collaborative governance activities strengthen the bi-directional relationships by providing the conditions for better alignment of activities at both levels and increasing the joint impact of activities at both levels.

The bi-directional relationships and their collective outcome can be seen in the participatory design process aiming to achieve accountability of AI systems for tribal emergency management. Participatory design involves the design of participant rules at the system governance level. Participants should include representatives and users from different stakeholder groups, such as FEMA's tribal affairs office, tribal leadership, tribal emergency management, and tribal user community. The position rules can appoint tribal emergency managers as system co-designers. Moving from the governance level to the technical decision level, these governance level rules prescribe the roles and responsibilities for making decisions at the technical design level. The reverse direction of the relationship involves information feedback on the performance of the AI-enabled chatbot resulting from implementing these participatory design features. The performance information used by participants at the governance level can result in modifications of the AI chatbot governance design, such as the creation of a coordinating committee.

4. Conclusion and Future Application and Research

4.1 Summary and Concluding Remarks

This paper is a development of a governance framework for the study of software accountability in the context of cross-sovereignty collaboration. The specific public administration challenge to address is emergency management that has become increasingly salient in light of the growing frequency and damage of natural and manmade disasters. The focal software system is AI chatbot that leverages natural language processing as an artificial intelligence capability. Such AI chatbot can benefit from the advancement of large language models and computational capabilities. This governance framework draws from collaborative governance in the public administration literature and the human-computer interaction (HCI) in the information science one.

The main contribution of this paper is the articulation of the governance structure and process and their relationships to the accountability results. Such articulation provides the foundation for theoretical and analytical advancements in the accountability of AI systems. The focal contribution lies in the cross-sovereignty context and marginalized circumstances facing indigenous communities.

The governance structure has three levels within the legal and policy framework for cross-sovereignty relations. The collaborative governance structure provides the high-level rules on what action is permitted, incentivized, or prohibited across the entities and individuals that are involved in the cross-sovereignty relationships. Emergency management is the public policy and management issue of focus. The next two levels are on software systems with AI chatbot as the focused system in this paper. Software system governance rules dictate who can participate in the design, who should be accountable for the design, who can get what information, and the benefits and risks associated with decisions. At the more technical level is the software system design, implementation, and evaluation. At this level, technical decisions are made to optimize the goals set by the governance body of the software systems.

Moreover, the levels are embedded from those of software system design, to the governance of such design, to the collaborative governance structure. The technical software system design operates within the goals, parameters, and rules set at the governance design levels. The software system governance rules need to be in congruent with those of collaborative governance structure dictating the eligibility and appropriate behavior of various organizations and individuals participating in the software governance. Such cross-boundary collaborative

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

governance structure embeds itself to the legal and policy framework for cross-sovereignty relations.

The main dynamics between levels are the collaborative processes and activities that address the bi-directional relations between the technical decisions on software systems at the most detailed level and the on decisions on the governance rules for structuring the decision-making, depicted inside the big oval in Figure 1. The governance rules dictate who can set the goals and functionalities of the software systems and who should be accountable for system performance. The technical decisions and their system performance shape the risks and benefits to various stakeholder groups participating and, to a certain degree, the legitimacy of their relative decision-making power. Moreover, there are dynamics jointly determined by actions taken at these two levels to impact accountability. Accountability is primarily measured by goal attainment. Complications lie in the divergent expectations of accountability across various stakeholder groups such as the tribal nations and U.S. governments. As depicted in Figure 1, the perceived accountability as the outcomes will feed back into some possible adjustment of the collaborative governance structure and the collaborative processes and activities for the bi-directional relationships.

4.2 Future Development and Research

The proposed governance framework integrates insights from various bodies of literature across disciplines and prescribes a comprehensive set of structure and process for future development of the theory and practice for AI system accountability. The next logical step is rigorous empirical investigation into the validity and relevance of the levels, their embeddedness, bi-directional relationships, and linkages of collective impact of multi-level governance structure on accountability, and the dynamism in feedback. This study will follow methodological guidelines developed from design science to understand the independent and combined contribution of context and governance design to impact (Meijer, 2024) Such investigation provides opportunities for validation, modification, or refinement of these conceptual elements and their relationships as depicted in Figure 1. Such investigation needs to include extensive policy and document review to study both the rules in the book. Moreover, extensive field research and user input would fill the details needed for the rules in practice and how these rules affect the software system development behavior and the perceived accountability.

Future research on governance for accountable AI systems can benefit from obtaining inputs on the structure and process of this governance framework from a variety of stakeholders. For emergency management, these include stakeholders such as tribal leadership and members and emergency management managers and personnel in U.S. governments. Moreover, the use of analytical framework and tools afforded by institutional grammar (Frantz & Siddiki, 2021) would advance the analytical rigor of studying rules and their configuration for understanding the entities involved and their actions and impacts.

Rethinking AI Readiness: A Framework for LMICs with Argentina as Case Study

Lucia Mariana Galarreta Bolia[a]

[a]AI4Gov alumni, Politecnico de Madrid and Politecnico di Milano, Spain- Italy, https://orcid.org/0009-0004-0167-0257, lgalarretab@outlook.com.

Submitted: 31 January 2025, Revised: 26 March 2025, Accepted: 21 April 2025, Published: 8 July 2025

Abstract. Standard indices and AI readiness criteria often do not adequately capture digital transformation's complex and context-specific dynamics in the public sector, especially in low and middle-income countries (LMICs). These tools typically provide decontextualized, static indicators that fail to consider historical processes and the evolution of local institutions. This paper examines Argentina's experience with AI adoption in the public sector using the Digital Government Ecosystem (DGE) framework —a context-sensitive tool that emphasizes the interaction of institutional, organizational, and governance factors. Drawing on empirical data, the study analyzes how AI initiatives have emerged, evolved, and been influenced by both national and subnational dynamics. It argues that understanding AI implementation as a situated and evolving process is essential for developing more meaningful assessments and strategies in LMIC contexts. The findings aim to contribute to more accurate, locally grounded approaches to analyzing and guiding AI integration in public administration.

Research paper, DOI: https://doi.org/10.59490/dgo.2025.1069

1. Introduction

Like many Latin American countries, Argentina grapples with many challenges to ensure the full exercise of rights. These obstacles include poverty, low levels of education, poor connectivity in remote areas, technological backwardness, economic issues, and challenges to federal government organizations. The country's complex agenda involves addressing these 'fundamental problems' while striving for government technological improvement and digital innovation. This dual focus is crucial to prevent further widening of existing inequality.

While the UN E-Government Survey 2022 ranks Argentina at 41, indicating that the country has a very high level of e-government development, there are no significant examples of applying AI in public policies in Argentina. This could indicate that other variables may be needed to address this lag between AI adoption in the public sector and its relatively high performance on e-government indicators.

How does a country with a very high E-Government Development Index (EGDI) like Argentina have only so few AI initiatives in its public sector? What minimum conditions does Argentina need to implement AI solutions in public policies that respect rights and address the diverse problems of its population? More importantly, could existing frameworks and indexes provide categories to analyze the readiness levels to enable the implementation of AI to improve public service delivery in Latin America, or should other categories and frameworks be sought and developed?

While existing frameworks and indexes can provide categories for analyzing the readiness or conditions for AI implementation in the public sector, a more comprehensive understanding of the context and needs that hinder AI implementation is crucial. This emphasis on thorough research is necessary to develop practical recommendations and guidelines for the Argentinian public sector.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

This research explores the existing frameworks and indexes and assesses their limitations. It also attempts to describe the conditions that influence how AI is adopted in the public sector in the complexity of the Argentinian case, based on data and policy analysis as of early 2024. Finally, it will propose a different approach to understanding how AI solutions are introduced into the public sector in Latin America, specifically in Argentina. Moreover, it is important to provide a more comprehensive perspective than those offered by some of the existing indexes.

2. State of the art and theoretical background

This section reviews existing indexes and AI readiness criteria, the main theoretical approaches, and the concepts used in this work. These will help frame a more situated analysis of AI implementation in Latin America and Argentina. It will explain how we understand the limitations of indexes as the only tool that provides information about national government conditions and readiness, mainly because they cannot grasp each context's challenges and opportunities. Federal or centralized governments are different, and for that, digital transformation is not adopted in the same way in each country. The adoption path of AI to low and middle-income countries (LMICs) differs from that of the wealthiest countries.

It also tries to address some crucial concepts to understand our case. Digitalization and digital transformation are required to analyze how AI is adopted in a country, and the importance of understanding the maturity of this digitalization process. One of the main objectives of this chapter is to define them and explain how they play a part in this analysis. It is also essential to understand why AI adoption in the public sector is related to the main objective of government, which, in my work, I frame as the provision of public value through different types of public policies and regulations.

2.1 The limitation of Indexes

There are many examples of public AI readiness indexes. Helen Tueni and Andrea Glorioso (2022)in their master's thesis, did an excellent job reviewing indexes and frameworks such as the OECD, the Government AI Readiness Index from Oxford Insights, and others. This builds on seminal work analyzing AI readiness in the public sector (Ubaldi, et al., 2019; Berryhill et al., 2019) that established foundational criteria for evaluating governmental preparedness for emerging technologies. Even though these have their differences in categories and approaches, the coincidences are focused on the following:

- Data and its availability, quality, and treatment.
- Public servant skills and technical capabilities around security and transparency.
- The existence of regulations and political decisions to modify cultural barriers propels changes and innovation in public services.
- Infrastructure and cybersecurity.

The Latin American Artificial Intelligence Index (ILIA) - developed by universities and governmental agencies from Chile, IADB, CAF, and UNESCO - represents a regional approach to measuring AI readiness. While it takes a more situated perspective and includes factors such as infrastructure maturity, data availability, and talent development, its categories largely mirror those of international indexes. Furthermore, as a general index rather than one specifically focused on the public sector, it provides limited insight into the particular challenges of government AI adoption.

All the indexes that analyze the readiness of the public sector have challenges in addressing the complexity of the problems that specific regions, such as Latin America and the Caribbean, would face in the walkthrough of AI development. These challenges extend beyond simple metrics to fundamental infrastructure issues. For instance, while indexes emphasize data availability and quality, they often overlook the fundamental challenges of digitalization and interoperability that many governments still face. Even when digitalization initiatives exist, as Novas's study (2019) of Argentina's Electronic Document Management platform shows, implementation often reveals significant operational challenges that indexes fail to capture.

The case of public servant capabilities also illustrates these limitations. Despite having over 137 post-secondary technology education programs in Argentina, only about 50% of public servants have postsecondary education, primarily in health and education rather than technology sectors (Maito, Garay, & Schachte, 2023). This example demonstrates how standard readiness metrics may miss the complex interplay between general education levels, specific technical skills, and actual public sector needs.

2.2 Digitalization

The previously analyzed indexes miss a crucial dimension in Latin America's AI path: the comprehensive

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

understanding and implementation of digitalization in the public sector. Adopting new technologies, such as AI, requires a deep understanding and a willingness to modify traditional and previous public sector activities and services.

In an exhaustive Inter-American Development Bank study, Estevez et al. (2024) propose an enlightening classification of government types based on their digital evolution. A "traditional government" delivers public services to citizens upon request, over the counter, and provided by a human public servant. A "digital government" advances this by delivering services through digital channels upon request, still provided by a human public servant. The most evolved form, an "automated government," delivers services proactively through digital channels, with algorithms replacing or complementing human public servants.

This classification aligns with Holmström's (2022) conceptualization of digital evolution in organizations. He identifies digitization - the process of converting analog to digital - as a preliminary stage that precedes digitalization, which involves using digital technologies and digitized data to establish new ways of working (Holmström, 2022, p. 330). Building on this foundation, he frames AI adoption as part of a broader digital transformation, defining AI readiness as "an organization's abilities to deploy and use AI in ways that add value to the organization. This represents "the profound transformation of organizational activities, boundaries, and goals to leverage the opportunities of digital technologies" (Holmström, 2022, p. 331).

Estevez et al. and Holmström's approaches provide valuable insights that standard readiness indexes often overlook. They emphasize that digital transformation is a progression of steps rather than a set of conditions, and both frameworks place value creation at the core of digital transformation efforts, including AI adoption. This progression is not just theoretical but represents a crucial roadmap for the public sector's future. Without successfully establishing traditional and digital government foundations, transitioning to an automated government, which relies on this accumulated history, structure, and capabilities, becomes problematic. This understanding underscores the urgency of addressing fundamental digital governance issues before governments can embrace AI's potential meaningfully.

2.3 Maturity of the Digital Environment

To understand how digital transformation unfolds in different contexts, Lorenzo (2016) introduces the concept of "maturity models" to indicate the incremental path organizations must take to increase digital maturity. The maturity refers to the formalization and optimization level of the process these organizations acquired (Lorenzo, 2016, p. 575) This concept is crucial for our work because it introduces the concept of time in a step-by-step development towards an ultimate ideal state of digital transformation, seeing it as a process, not as a moment, like indexes do. At the same time, maturity models focus on organizations as their core unit, which is a limitation for understanding an ecosystem's broader capabilities, as this work aims to do.

The historical development of digital government demonstrates the concept of maturity in this context. In high-income countries, some governments began collecting digital information and establishing institutional frameworks, infrastructure, technology, and human capacity as early as the 1950s. This process was driven by the need to enhance efficiency and manage information, alongside the introduction of computer technologies. This early adoption of information technology laid the groundwork for the development of electronic government and facilitated digital transformation in subsequent years (Margets, 2022). These initiatives are characterized by their long-term policies, which are less subject to changes in political administration. They are considered strategic, as they provide resources and infrastructure over time.

According to Estevez et al. (2024), one crucial condition for implementing new technologies in a digital governmental ecosystem is to do so with proven and mature ones, guaranteeing safety and respect for citizen rights. This principle emphasizes the importance of ensuring that digital systems and processes have reached an appropriate level of maturity before they are widely implemented, particularly in contexts where institutional capacities may be limited or resources are constrained.

The maturity criteria apply fundamentally to digital environments and their readiness for digital transformation. AI implementation becomes desirable when the digital ecosystem demonstrates sufficient maturity to guarantee safety and rights protection across different government levels. This maturity requires time, sustainability, political decisions, and resources—elements that are often scarce in developing regions. Therefore, the challenge goes beyond technical capabilities; it also involves prioritizing long-term policies, ensuring sustained resource allocation, and maintaining institutional consistency. These factors are essential for fostering robust digital ecosystems that can support the adoption of AI.

2.4 Public Value in Digital Transformation

One of the main objectives of a government is to create public value: "To produce public value with no (or minimal) waste of government resources such as time, effort, authority, and others" (Estevez, Janowski, & Roseth, 2024, p.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

9). This objective becomes particularly critical in the context of digital transformation as it involves three interconnected elements: political aspects (public value creation), operational capabilities, and strategic capabilities. These elements form the foundation for transformation towards digitalization and automation, where the potential to reduce waste and improve resource management offers significant efficiency gains that cannot be ignored or postponed. In the current technological landscape, the risk of failing to deliver public value increases when governments undermine the priority of addressing digital transformation and automation.

The pursuit of public value through digital transformation can follow multiple pathways, each with its own implications for government effectiveness. These pathways manifest in different dynamics:

- Scaling and maturing the entire digital governmental system—This is a comprehensive approach that seeks to enhance public value creation across all government functions and levels simultaneously.

- Fragmentary efforts in different domains and levels of government—This is a more targeted approach, where public value is enhanced in specific areas or services based on immediate needs or opportunities.

- One-shot implementations in specific contexts - Focused interventions addressing particular public policy problems, often in response to well-defined challenges or opportunities for innovation.

These pathways are not mutually exclusive but rather represent different strategies for enhancing public value through digital means. In the Latin American context, these multiple approaches often coexist, reflecting the region's complex reality of public administration. While traditional recommendations advocate for a centralized, whole-of-government strategy to provide coherence in data, technologies, and infrastructure (Estevez, Janowski, & Roseth, 2024, p. 78), the practical pursuit of public value often requires a more flexible approach. This results in the coexistence of bottom-up and top-down initiatives in public policy design, each contributing differently to public value creation through digital transformation.

2.5 Public policies, frameworks, and legislation

The regulatory landscape for AI presents significant challenges and variations globally. Currently, the EU is the only major player with comprehensive AI legislation. At the same time, the United States has taken a more flexible approach through an executive order that outlines regulatory directions. China, meanwhile, has established strict state control rules. Despite these different approaches, unified international AI governance remains a notable vacancy, creating uncertainty for countries developing their own regulatory frameworks. (Klein & Patrick, 2024)

In response to these regulatory challenges, some jurisdictions explore innovative governance approaches such as regulatory sandboxes. As analyzed by the Economic Commission for Latin America and the Caribbean (ECLAC) (Guio, 2024), these sandboxes offer a controlled environment to test new technologies and regulatory frameworks before full-scale implementation. They represent a balanced approach between innovation and regulation, allowing governments to understand and address potential risks while fostering technological advancement. However, in Latin America, the adoption of such innovative regulatory tools has been limited, with only Brazil, Colombia, and Bermuda implementing sandbox initiatives (Guio, 2024). This limited adoption reflects a broader challenge in implementing flexible regulatory frameworks that can support AI innovation while protecting public interests.

This regulatory context has particular implications for LMICs. Without global AI governance frameworks, these nations face significant barriers in accessing and benefiting from AI innovations in crucial areas like healthcare, education, and government efficiency. The lack of established international standards and governance mechanisms exacerbates existing technological gaps between LMICs and more prosperous countries, often leaving developing nations to work in isolation, cut off from markets, funding, and technological innovation opportunities.

The regulatory landscape thus extends beyond mere legal frameworks to encompass broader questions of technological access, innovation capacity, and international cooperation. As countries develop their AI policies and regulations, they must balance multiple considerations: promoting innovation, protecting public interests, ensuring ethical use of AI, and maintaining competitiveness in the global digital economy. For LMICs, this balance is particularly challenging given resource constraints and the need to catch up with rapid technological advancement while ensuring appropriate safeguards are in place.

2.6 Revisiting Key Concepts through the LMIC Lens: Towards an Integrative Framework

The previous sections have outlined several key dimensions that shape how digital transformation and AI adoption unfold in the public sector: readiness indexes, digitalization processes, digital maturity, public value creation, and regulatory frameworks. When these dimensions converge in LMIC contexts, they create a distinct landscape that demands careful consideration. Unlike high-income countries that underwent gradual digital evolution over

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

decades, LMICs face unique challenges in their digital transformation journey, requiring them to address basic digitalization needs while simultaneously pursuing advanced technological capabilities.

Traditional indexes and "readiness criteria" often prove insufficient in this highly contrasting context, offering merely listings of good practices rather than foundational guidelines for realistic AI implementations in the public sector. This limitation stems from their failure to account for core elements such as digitalization infrastructure, resource constraints, and the need for long-term policies and strategies on human resources and talent development.

The contrast between high-income and low- and middle-income countries is particularly stark in their digitalization pathways. While developed nations followed planned and gradual digitalization efforts, LMICs typically experience rapid and disorderly changes, leading to less structured and more complex digitalization processes. The UN E-Government Survey consistently highlights these disparities in digital infrastructure and capacity between developed and developing nations.

This situation is further complicated by the political dynamics in LMICs, where changes in administration often result in policy discontinuity or abandonment, jeopardizing previous achievements. The challenge of strengthening digital ecosystems becomes particularly acute when considering system scalability, which requires sustained resources, long-term projects, and institutional consistency across different governments. For instance, some systems may become inoperative when national governments fail to provide resources to provinces or municipalities, severely limiting possibilities for scaling and innovation. In federal countries like Argentina, this challenge is amplified by the high cost of political transactions, where party politics often dominate negotiation processes (Palumbo, 2019, p. 143).

The creation of public value, which should be the primary goal of any government, becomes especially critical in LMICs given their complexity and limited resources. Unfortunately, we often observe the implementation of "canned responses" that provide little real benefit while consuming precious resources. This creates a fundamental tension: how can these countries harness AI's benefits for public value creation while simultaneously building the comprehensive digital foundation that the literature suggests is necessary?

The global context further compounds these challenges. The absence of global AI governance particularly affects LMICs' ability to access and benefit from AI innovations in areas such as healthcare, education, and government efficiency. Without such governance, the gap between LMICs and more prosperous countries continues to widen, often leaving developing nations to work in isolation, cut off from markets, funding, and technological innovation opportunities.

However, regional initiatives offer some hope. Despite historical fluctuations in Latin American cooperation, AI has emerged as a unifying agenda, exemplified by the Santiago Declaration. This agreement establishes a workgroup for an Intergovernmental Artificial Intelligence Council for Latin America and the Caribbean, which represents a pivotal moment for the region. Despite varying national positions, including Argentina's, this initiative creates an opportunity to address shared regional challenges and ensure the Global South's perspectives are included in broader AI discussions.

Given these realities, Latin America and the Caribbean must develop frameworks that better reflect their circumstances and actual position in the AI adoption journey. These frameworks should account for the unique challenges and opportunities present in the Global South, moving beyond traditional assessment models to create more relevant and actionable guidance for digital transformation. This recognition forms the foundation for the analytical framework proposed in this work.

3. The Argentinian Case

In this section, we will analyze Argentina's adoption of AI in the public sector through the conceptual lens developed in the previous chapter. This analysis will allow us to identify Argentina's specific challenges and opportunities in implementing AI technologies within its complex institutional framework. First, we will examine the most significant AI initiatives implemented in recent years, evaluating not only their technical characteristics but also how they reflect the broader digital maturity of Argentina's public sector. After establishing this empirical foundation, we will assess the country's digital infrastructure, data governance practices, and institutional readiness to develop a comprehensive understanding of Argentina's digital ecosystem and its capacity for AI integration.

This analysis reflects the situation in Argentina as of early 2024. While specific digital government initiatives may evolve with changing administrations, the structural challenges and institutional arrangements tend to persist beyond political transitions. Readers should consider potential developments that may have occurred after the research period.

3.1 AI experiences in the Argentinian public sector

Despite the global acceleration of AI technologies and their increasing adoption in public administration worldwide, Argentina's public sector shows a relatively limited implementation of AI solutions. The existing initiatives can be categorized into several functional areas:

- Citizen-facing conversational AI

The national government's "Tina" chatbot is a virtual assistant that is available 24/7. It provides citizens with information on more than 200 procedures, programs, scholarships, subsidies, and consultations on health, inclusion, justice, transparency, and gender issues.

Similarly, Buenos Aires City implemented "Boti," an AI chatbot for citizen assistance. During the COVID-19 pandemic, this platform was enhanced with "IAtos," an AI tool that detected potential COVID infections by analyzing user cough audio samples.

- Judicial process automation

The "Prometea" system applies artificial intelligence techniques to prepare court opinions automatically. The development of PROMETEA began in 2017 by the Prosecutor's Office in the Autonomous City of Buenos Aires, Argentina. This tool increases efficiency: brought a reduction from 90 minutes to 1 minute (99%) for the resolution of a tender process, from 167 days to 38 days (77%) for processes of the requirement to trial, and from 190 days to 42 days (78%) for protection housing with citation of third parties, among others. (Estevez, Fillottrani, & Linares Lejarraga, 2020)

Like Prometea, there are other experiences in the provinces' justice systems. The provinces of La Pampa and Río Negro are using AI to improve the process and the times of the procedures.

The State Prosecutor of the province of Buenos Aires implemented Velox, a machine-learning model used to help lawyers prepare for the tax hearing issued by the State Prosecutor.

A few additional experiences can be mentioned (OECD and CAF, 2022). While the AI initiatives in Argentina demonstrate the potential of AI to enhance efficiency and service delivery, they often rely on relatively limited technologies. For example, chatbots like Tina and Boti primarily use rule-based systems or basic natural language processing, which can be helpful for citizen interaction. Although Prometea and Velox employ more advanced AI techniques, they focus on automating specific tasks within defined domains. These initiatives are isolated efforts rather than examples of widespread AI adoption within the public sector. This situation highlights the absence of a strategic, national-level plan for AI implementation in Argentina, leading to a fragmented landscape where AI initiatives are concentrated in specific areas without integration into the overall governmental structure.

This fragmentation suggests that, despite technical experimentation, AI adoption remains disconnected from systemic public sector transformation. Understanding this misalignment is critical for informing institutional reforms and capacity-building efforts. These patterns of AI adoption align with broader regional trends identified by Aguerre (2020), where AI implementations in Latin American public sectors tend to be isolated, technologically conservative, and concentrated in urban centers rather than integrated into comprehensive digital transformation strategies.

These experiences highlight a public sector that, despite making significant progress with concrete and replicable solutions, still struggles with strategic coordination. In Argentina, the use of AI in the public sector is mainly focused on improving administrative efficiency and automating processes. However, as we will present in 3.2, there is a lack of a clear governance framework to ensure sustainability, transparency, and social participation in AI development. This underscores the need to transition from isolated technological adoption to a comprehensive and deliberative public policy on AI.

To fully understand the limited scope of these AI initiatives, it is important to consider the scale of Argentina's public sector. Beyond the national administration, Argentina consists of 24 provincial governments, over 1,900 municipal governments, and distinct systems across the executive, judicial, and legislative branches. Given this complex and decentralized structure, the identified AI initiatives represent isolated cases within a much larger and more intricate governmental landscape. This institutional complexity suggests the need for a more nuanced framework to analyze digital readiness—one that accounts for the multilevel nature of governance and the evolutionary process of digital transformation, as will be proposed in Section 4.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

3.2 The current Argentinian digital public sector context

The E-Government Survey 2022 ranks Argentina 41st, reflecting a high level of e-government development. However, this overall ranking obscures a more complex reality within Argentina's federal structure, where uneven digital adoption leads to significant variations across different levels of government. Below, we will outline some observations about the Argentine landscape.

Digital Administration System: Argentina's unique federal structure and multiple independent governmental levels present a complex digital landscape. Provinces and municipalities responsible for decentralized services like health, education, and taxes contribute to this complexity. This context underscores that a high level of digitalization at the national level does not fully capture the country's digital reality.

Argentina presents a heterogeneous implementation scenario in the foundational area of administrative document management. Of the twenty-three (23) provincial governments and one federal district, eight (8) provincial executive governments have developed their own digital administrative file systems, while sixteen (16) use the system provided by the national government (called Electronic Document Management or GDE in Spanish). This diversity creates significant interoperability challenges, stemming from both technological differences and varying implementation timelines. For example, while the national government began using the GDE system in 2015, five provinces only adopted it very recently, between 2023 and 2024. At the municipal level, digital adoption is even more limited, with only about 90 municipalities (out of more than 1,900) using GDE as of early 2024.

One technology that has achieved widespread adoption is the digital signature, which enables legally binding electronic authorization of documents, providing security, authenticity, and non-repudiation for digital transactions. Every province has implemented this technology, demonstrating that cross-government digital tools can succeed when they offer clear value and align with existing legal frameworks. Implementing transborder digital signature capabilities with Uruguay, Chile, and Brazil further illustrates the potential for regional digital integration when adequately coordinated.

This uneven landscape affects every element of the digital ecosystem, from data quality and availability to cultural change and digital literacy among public servants. Digital platforms represent just one dimension of AI readiness, which depends on data governance, infrastructure, human capabilities, and regulatory frameworks.

Data Governance: Even though the national government has an open data policy, the volume of datasets available could be higher. With around 1200 datasets, the datos.gob.ar portal provides data from the national government and technical assistance to provinces and municipalities if they are willing to promote a data governance policy. Currently, only 14 provinces and 80 municipalities have open data portals. The same methodology is used with interoperability and authentication platforms, where the national government puts them at the disposition of the provinces. However, this adoption is entirely voluntary and sometimes challenges the technology teams of each part. In fact, the national government is promoting compatibility with provincial platforms that use X-Road, but only two start the first tests. There is no doubt that the improvement in the coordination between agencies and governmental levels to make better use of data already existing is a necessity that breaks the silo logic of the data and starts to create a fertile data governance space where AI could thrive.

Infrastructure Development: In the case of infrastructure, as we said previously, even though the internet coverage is high, it reproduces the inequity of the service distribution across the country. Some locations and populations still need to be communicated, impacting the digitalization level of government services. Moreover, connectivity is mainly through mobile phone networks, which are only used in individual communication activities or are limited to recreational use. Therefore, we should highlight that provinces and municipalities have minimal capabilities to invest in infrastructure because their budgets are mostly compromised by the payroll of their administrations and other priorities. That is why the investment in digital infrastructure for the provinces and municipalities might come from the national government or internationally funded projects from different organizations. In LMIC, that is the rule.

At the national level, the landscape is better, and the national government has more infrastructure. Argentina has ARSAT, at least for the moment, a national company that provides telecommunication services to the central government and the provinces that can afford them. For example, ARSAT has a data center and cloud services and is one of the critical actors in extending the country's optical fiber network (Federal Fiber Optic Network, in Spanish REFEFO). Argentina's national government also has one of the top 500 supercomputers in the world.

Even though there are still many things to do, Argentina has achieved vast improvements at all its governmental levels related to digital governance and is in a privileged position in the region.

This work does not intend to investigate every case of every subnational government per se. Still, it is essential to describe this complexity to explain why AI tools remain isolated cases dispersed in different agencies along the country's territory. Hence, digitalization at all levels and across the country is a leading condition that governments should address to adopt automation tools such as AI. To enhance what is missing, the maturity of the national digital ecosystem should be analyzed as a whole, with all the governmental levels and stages.

Institutional readiness and human capacity: as mentioned, Argentina is a federal country with different government levels and various institutional designs, where updated and out-of-date technologies coexist. Access to a shared digital infrastructure will not be achieved in the short and medium term because of the absence of a strategic plan for digitalization at all governmental levels that includes a unified infrastructure and interoperable systems. The need for more economic resources is one of the main reasons. This is why data exchange, data governance, and interoperability become core challenges.

At all levels of government, it is still more challenging to have in-house technological expertise than in the private sector, and provincial and municipal governments find this even more difficult because of the existing gaps in resources, education, state capacities, etc. These differences operate between provinces and municipalities and between them and the national government. Where an agency, a ministry, a province, or any part of a government is lucky enough to have a couple of well-trained people in the technology team, empowered to innovate, an improvement is willing to rise. These isolated, short-term solutions show the absence of a national plan or strategy to incorporate AI tools into the public sector at all governmental levels.

Even if this is a problem that every nation has worldwide, in the case of LMIC, the consequences provoke an overreliance on digital and AI solutions made by private companies that have a profound ignorance of government processes, their activities, the rights that must be attended to in public matters, etc. This is crucial to understanding the dispersed experiences with AI solutions in the Argentinian public sector.

Today, with AI development, the risk is high and costly for the government to leave private companies entirely in charge of their AI projects. Even if they outsource the technological expertise, there are many components, such as legal expertise, internal processes, and borderline cases, that only civil servants can provide (Estevez, Janowski, & Roseth, 2024, p. 87). For example, in the case of the TINA chatbot, the UX team is in-house (government) even though the national government contracts with Meta (because of the use of WhatsApp) and with Botmaker to integrate data, API, etc., and deploy the chatbot. It is essential to highlight that even if some AI experiences are partly outsourced, most cases we introduce in the 3.1 part are entirely in-house experiences.

Latin America and the Caribbean are rich in linguistic diversity, with Spanish and Portuguese serving as the predominant national languages alongside many other dialects and languages of native and different ethnicities. This diversity is not a hindrance but a valuable asset that enriches our region. However, it does present a challenge in developing a regional or national technological sector that genuinely reflects the needs and interests of our diverse continent, as the industry predominantly uses English as a universal language. This characteristic underscores the disparities between the South and North and the private and public sectors. The reliance on the private sector for AI or other outsourced projects often leaves the public sector in the hands of companies that do not even program in the same language.

One of the critical criteria for readiness, as identified by indexes, is the acquisition of skills and technological competencies by civil servants. This is crucial, as it enables the government to be more efficient and effective without outsourcing technological development. In the global AI race and the battle for global power, the rapid adoption of new technologies is more feasible if the innovation and capabilities are tailored and hosted within the government (Margets, 2022). Beyond highlighting the risks of excessive outsourcing, it is essential to outline

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

strategies to foster in-house AI capacity. These include creating interdisciplinary teams within government units, establishing public sector AI labs, investing in upskilling programs for civil servants, and fostering partnerships with local universities and research centers. Such efforts build technical expertise and enhance institutional memory and autonomy in AI governance. However, achieving this is more challenging in LMIC because public servants need specific skills, and the technological industry is structured and tailored for the central and wealthiest nations.

In 2019, Argentina unveiled an AI National Plan, a significant step that, unfortunately, has not been fully implemented. Since then, we have seen some scattered governmental actions that could pave the way for creating an ecosystem conducive to AI solutions, but there is still much room for growth. Notable among these actions are a couple of regulations and incentives for the Argentinian case: the AI National Plan (2019), which is yet to be executed, and a Disposition with recommendations for using AI in the public sector (2023). The disposition, titled "Recommendation for a reliable Artificial Intelligence," marks the first regulatory act of the Argentine state in this field. It is based on the UNESCO "Recommendation on the Ethics of Artificial Intelligence," Asilomar AI Principles, and OECD AI Principles, among other principles and papers on the topic.

The absence of global AI governance and the limited regulation framework in Argentina make the condition regarding the existence of regulation, according to what indexes usually indicate, far more complex for LMIC to achieve. The geopolitical competition, the inexistence of a global AI governance, and the breaches in access to every element that enables AI expansion (such as digitalization, funding, technology, infrastructure, education and scientific knowledge, markets, etc.) made it way more difficult for these types of countries to create regulations that could bring security, guarantee rights and create a fertile ground to grow AI initiatives and are the dominant barriers to AI implementation in the public sector. However, it does not imply that AI could not emerge.

Formulating a national AI strategy is a pressing need that must be co-designed, at least with the provinces. A comprehensive national strategy should encompass the entire public sector, not just the national government. In this context, Argentina's various thematic federal councils serve as institutional spaces where all provincial and national governments can collaboratively design strategies to address the sector's needs and challenges. For instance, the Federal Council of the Public Service (in Spanish, Consejo Federal de la Función Pública – COFEFUP) has been a critical platform for the provinces and national government to forge agreements and public policies for 30 years.

Section 4 introduces the Digital Governmental Ecosystem (DGE) framework, a novel approach used in this study to analyze the dynamics of digital transformation (and ultimately AI adoption) within Argentina's public sector more comprehensively than indexes.

4. Different Approaches for Argentina and Latin America

To clarify how we can address Argentina's reality as part of a Latin American landscape, we cannot have precise analyses of the readiness for AI implementation in public service if we ignore the degree of evolution of the digital environment.

As we have seen, the ecosystem concept is more related to the whole digital environment, including the private sector, all kinds of organizations from the social sector, and governments. At the same time, the maturity concept is usually used at the organizational level, undermining the relevance of a holistic view of the government's digital situation at all levels in the federal organization.

Developing specific analytical criteria to analyze the Argentinian case more precisely and gain a deeper understanding of AI implementation in the public sector is imperative. These criteria, which should consider the government as an ecosystem, will incorporate indicators that can gauge the level of maturity and, consequently, the potential for AI adoption in the public sector. Next, we will explain and describe this concept and how it interacts.

4.1 Defining the Digital Governmental Ecosystem (DGE)

To analyze the Argentinian case and other LMICs more precisely, it is necessary to move beyond traditional frameworks and indexes. This work proposes the concept of the Digital Governmental Ecosystem (DGE) as a more comprehensive and nuanced approach to understanding digital transformation and AI adoption in the public sector.

The DGE framework draws upon concepts from various theoretical perspectives. The Digital Governmental Ecosystem (DGE), as Systems Theory establishes, is understood as a complex system composed of interconnected components. Changes in one component can trigger cascading effects throughout the entire system. This

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

theoretical approach highlights the interconnectedness and interdependence of elements within the public sector, aligning with established research in systems theory and political systems. Notable scholars in this field include Easton, Parsons, Almond, and Powell, among others. (López Montiel, 2008).

Of course, and as its name indicates, DGE is based on the Ecosystem as a Model. Crucially, the DGE framework adopts the concept of ecosystems from the natural sciences. The ecosystem, understood as the "set of organisms and their physical environment interacting in a place," provides a globally applicable and flexible model for understanding complex systems. Its applicability across temporal and spatial scales and adaptability to diverse situations make it helpful in analyzing the digital government's dynamic and evolving nature. Any location presenting these conditions could be considered an ecosystem, regardless of size or the brevity of interactions. (Armenteras, et al., 2016).

Lastly, DGE is based on the theoretical construct of Digital Governance. It incorporates principles of digital governance, emphasizing the need for effective leadership, coordination, and regulation to guide the development and evolution of the digital ecosystem. This perspective underscores the importance of governance mechanisms in shaping the adoption and impact of digital technologies in the public sector (Naser, 2021).

The Digital Governmental Ecosystem (DGE) is a comprehensive construct encompassing all the institutions and agencies within the public sector. This includes:

- **Governmental Structures:** The various powers of the state (executive, judicial, and legislative) and the different levels of government (national, provincial, and municipal).
- **Technological Infrastructure:** The systems, technologies, and data utilized by governmental entities.
- **Regulatory Framework:** The regulations that govern the operations of public sector institutions and agencies.
- **State Capacities:** The resources, skills, and capabilities that enable the delivery of public value.

4.2 DGE Maturity

The maturity level of the DGE is assessed based on two combined variables: **evolution and coverage.**

Evolution refers to the main activities undertaken by governmental entities, progressing from analog and traditional government to digitization, digitalization, and ultimately, digital transformation (Holmström, 2022), representing the highest level of the evolutionary process. For example, if the main activities are focused on digitization, the DGE has a low level of evolution.

Meanwhile, **coverage** indicates the extent to which different government levels and agencies have been impacted or need to be impacted by prior activities such as digitization and digitalization. Coverage can range from narrow and dispersed to broad. For example, we can find a highly digitalized national government in Argentina, but the provinces and municipalities are behind in this process. So, the DGE's coverage is narrow and could be placed in the dispersed or medium position.

The maturity of the DGE influences the adoption and implementation of digital technologies, including AI, in the public sector. A mature DGE provides a more favorable environment for successful AI adoption, while a less mature DGE may face challenges in effectively leveraging AI's potential.

4.3 How does all this work together

The element of coverage in a federal organizational government is crucial in the process of digital innovation and AI incorporation in the public sector because citizens' primary services and data (and their lives) are located and generated in their closest governmental levels, even though some tools and solutions are deployed at the national level and then transferred to provinces and local governments.

If the evolution of the DGE is low and in a small number of agencies and government levels, public value will not be achieved to its full potential. The relationship between both elements will show us how mature the DGE is. By maturity, as we previously indicated, we identify how this relation is and how it materializes in government actions with all the elements that public value requires: efficiency, effectiveness, and capability to resolve people's problems. A thriving DGE that brings public value leads to a more comprehensive implementation of AI in the public sector.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

When the DGE has a low or middle level of maturity, digital transformation activities such as AI adoption are expected to be dispersed, with sustainability, scalability, and interoperability deficiencies. Mostly, no part of a strategy. It is more likely to be none or a few pieces of legislation.

4.4 The Argentinian DGE

Until 2023, Argentina seemed to be on the road to increasing its DGE maturity, even with back-and-forth. Considering the information in Chapter 3 and our new framework, we can quickly locate Argentina at a middle level of maturity, with some elements highlighting the tendency to increase it.

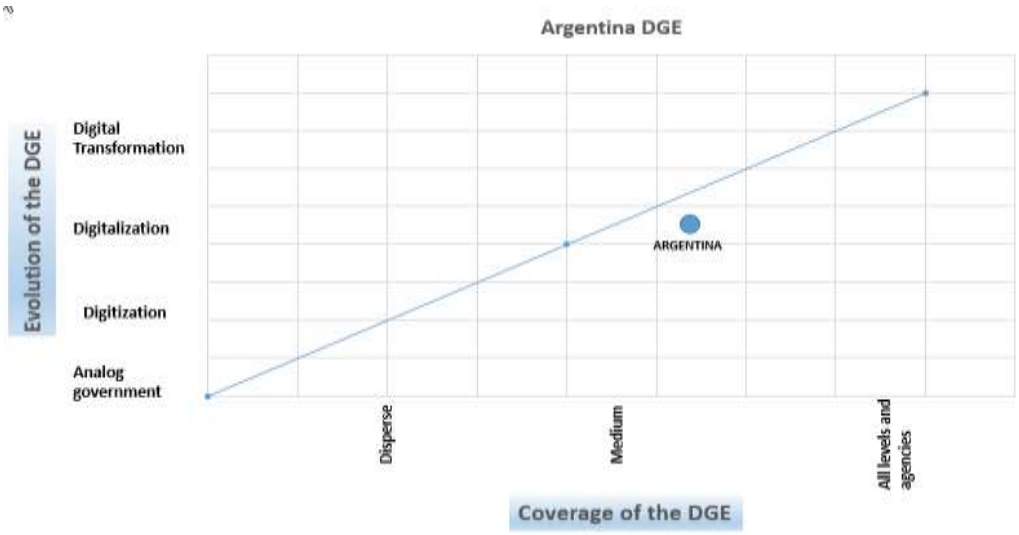

Fig. 2 Argentina DGE maturity location. Source: Author's elaboration

As Figure 2 shows, Argentina mainly covers all the middle maturity conditions. However, we can identify the tendency to cover all the government levels because the national government and all the provinces are already in the evolution stage of digitalization, even though many municipalities and some agencies at all levels are behind. We can also identify that the infrastructure and connectivity with ARSAT as a provider of cloud services and the REFEFO are closer to the conditions of a highly mature DGE. Moreover, even though AI initiatives in Argentina are dispersed, this shows a tendency to evolve into a digital transformation stage if the state's capacities and resources in AI tools could be strengthened over time.

Nevertheless, the actual situation enlightens that this level of DGE maturity brings only the possibility of AI implementation in some silos or situations that are more related to the disparity and gaps between agencies and governments: those who have some state capacities (recourses, skills, infrastructure, coordination between intra and extra state, etc.) could deploy an AI solution to a public problem.

Returning to our question about how LMIC can obtain the benefits of AI adoption to increase public value when we still need to go ahead with digitalization, the answer is given by the national experiences, as we did with Argentina. Even though the ideal condition shows that digitalization comes first before AI, other elements enable AI in the public sector to emerge in this case, and they all provide elements to the maturity of the DGE.

The process is simultaneous and unique for each case and evolves according to the decision-making. Every country's process differs and could take different approaches. Some could strengthen every level of government first and then focus on evolving the DGE. As we already indicated, these processes in Latin America are disorderly.

This framework guarantees a more realistic and individualized approach for every national case. It provides a dynamic view of the strengthening process of the DGEs where the "readiness criteria" are not the center of the analysis. We can avoid the need to force or dismiss a case if it does not apply to an AI readiness index. Digital transformation and automation are fundamental parts of AI's emergence in the public sector, but not determinants of its existence. Other elements are very distinctive to each process. Reediness criteria tend to make some elements invisible or overestimate some aspects, depending on how or who analyzes a national case.

Conclusions

This work tried to address the Argentinian public sector's current situation concerning AI implementation against a Latin American backdrop. The analysis includes the elements and processes that structured the implementation

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

of AI as one of the stages of the digitalization of government and its transformation to automation. As the indexes indicate, Argentina requires consistent development of its infrastructure, frameworks, regulations, and a well-trained public servant body. However, we must extend our analysis beyond the existence or absence of these requirements to explain how AI is being implemented in Argentina, since these tools cannot grasp contextual factors involved in digitalization as a prerequisite for a comprehensive inclusion of AI across government.

It is necessary to dive into the DGE, analyze it as a whole, and take it as a living creature that grows and expands in disorder, in different directions, and with different velocities. By doing so, we can approach a possible explanation of why Argentina has a dispersed and small amount of AI experiences in the public sector. We can also try to seek solutions related to the structural needs of the DGE instead of focusing on resources and time on isolated efforts, like a reskilling program for public servants without knowing what they need, or a strategy or regulation that does not consider the current situation of the provinces and local governments. In the end, this kind of action only increases the internal gaps between provinces or municipalities with more resources and between them and the national government, and, of course, increases the inefficiency in government.

The maturity of the DGE is a concept that brings the idea of process, growth, and movement. The variables used in this work, such as evolution and coverage, bring to light that in one DGE, there coexist different realities, such as municipalities without relevant internet access and provinces with a ministry that still uses paper system files with a national government that provides digital ID or a city the integrated chat-GPT to the city chatbot. With this in sight, it is possible to design better public policies customized to each reality and co-design without leaving anyone behind. It also allows leveraging the existing AI solutions and digital transformation momentum that some agencies, governments, and stakeholders are conducting to benefit the whole DGE.

Therefore, we can provide some insights related to various topics of this work. Here are some limitations and future research ideas.

- Indexes are an excellent start to introduce some realities and comparatives between countries, but they are insufficient to explain the profound reasons and singularities of a digital transformation process. Readiness criteria would overestimate or put aside elements or experiences that are relevant or interesting for each case.

- AI implementations can emerge even though the path to digital transformation has not been completely achieved. This is a sign of a certain level of maturity of a DGE and must be seen as a characteristic and process, not as a lack of something.

- LMICs should simultaneously address catching up to digital transformation; meanwhile, they should try not to be left behind and minimize the loss of public value in delivering public policies.

- The LMIC regulation should address specific problems and particular characteristics; try to resolve each DGE's issues and not emulate foreign experiences.

- Resources of all kinds (state capabilities, infrastructure, etc.) remain the main agenda for the LMIC. In federal countries, this must be addressed at all governmental levels, in a coordinated way.

While this study provides valuable insights into the Argentinian public sector's current situation concerning AI implementation, several limitations should be acknowledged. First, the focus on a single case study limits the generalizability of the findings to other LMICs. Future research should consider conducting comparative studies to analyze AI adoption in the public sector across multiple regional countries.

Second, the availability and quality of data on AI adoption in the Argentinian public sector posed challenges to conducting a more comprehensive analysis. Future research could explore alternative data sources or develop new data collection and analysis methodologies.

Third, the Digital Governmental Ecosystem (DGE) framework, while offering a novel approach to understanding AI adoption in the public sector, requires further validation in different contexts. Future research should continue to develop and refine this framework to enhance its applicability and generalizability.

Finally, this study focused primarily on AI adoption in the public sector. Future research should broaden its scope to explore other important aspects of digital transformation, such as citizen participation and digital inclusion, to provide a more holistic understanding of the phenomenon.

These limitations highlight potential avenues for future research that can build upon this study's findings and contribute to a more comprehensive understanding of AI adoption in the public sector in LMIC.

The wallet demarcation problem: developing a taxonomy for classifying digital wallets

Bert Lukkien [a*], Mark de Reuver [a], Nitesh Bharosa [a]

[a] Faculty of Technology, Policy, and Management, Delft University of Technology, Delft, the Netherlands, J.A.Lukkien@tudelft.nl, 0009-0005-0540-8771.

Submitted: 31 January 2025, Revised: 26 March 2025, Accepted: 21 April 2025, Published: 26 May 2025

Abstract. Digital wallets are emerging as new tools that provide citizens with control over their personal data while allowing innovation in service delivery. Wallets promise various functionalities, from authentication, authorisation, and signing, to storage and generating qualified electronic attestations. Given the potential, policymakers and service providers face significant challenges in selecting, developing, implementing, and regulating digital wallets due to the lack of clarity about their characteristics. This paper focuses on this lack of clarity. Through a socio-technical systems theory lens, we developed a comprehensive taxonomy for classifying digital wallets. Our empirical analysis reveals a taxonomy of 47 characteristics in 14 dimensions. The contribution of this taxonomy is two-fold. Firstly, it can help develop a more precise theory on specific types of wallets. Secondly, actors in the field can use the taxonomy for more granular communication on wallet development and adoption challenges, standardisation efforts, and policy development.

Keywords. wallet, digital identity, public value, privacy, taxonomy, responsible data sharing, eIDAS, Data Governance Act, policy instruments, personal data space, personal data.
Research paper, DOI: https://doi.org/10.59490/dgo.2025.1039

1. Introduction

Interactions in society are more digital than ever. In some countries, people order their groceries from the supermarket online; apply for a building permit via the municipality's app and book a trip via the travel agency's website. When interacting with (semi)public agencies, we also expect public values to be protected. In many cases, efficiency and ease of use have been the dominant values in the design of digital systems. Considering security scandals and privacy regulations, values such as privacy, choice, security, and trustworthiness have become increasingly important. One of the ways to promote privacy, choice, security, and trustworthiness in the digital exchange of personal data is the introduction of digital wallets. However, a digital wallet is an ambiguous concept. Research has revealed multiple types of wallets with various functionalities and objectives (Degen & Teubner, 2024).

The European Union is also introducing a digital wallet, the 'European Digital Identity Wallets (EUDI Wallet).' This wallet should offer private users and businesses a universal, trustworthy, and secure way to identify themselves when accessing public and private services across borders. Examples of how the EUDI wallet can be used include opening a bank account, proving one's age, renewing medical prescriptions, renting a car, or displaying their flight tickets."[1] EU Member states have been given the legal obligation to provide all citizens with a digital wallet upon request[2]. These can be provided by the Member State, on behalf of the Member State, by a private party, or by a private party with recognition from the Member State[3].

[2] eIDAS Article 5a(1)
[3] eIDAS Article 5a(2)

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

However, despite the legal framework available, it is still unclear what that digital wallet under eIDAS will look like. This new legislation does not aim for uniform implementation but leaves EU Member States and wallet providers with relative freedom of choice. It describes a set of minimum requirements about functionality, interoperability, security, and respect for privacy, as formulated in the General Data Protection Regulation (GDPR)[4]. Therefore, we can expect a wide variety of implementations across member states, each with its own focus and user context. Requirements such as protocols and interfaces are also specified in the European Digital Identity Wallet Architecture and Reference Framework (ARF)[5] and in five implementation acts[6].

As discussed in previous work, public and private service providers are struggling with the development and implementation of digital wallets in general and the EUDI wallet in particular (Lukkien et al., 2023). An explanation can be found in the complex environment in which wallets must operate. According to the ARF, wallets must be implemented in a multi-actor ecosystem with various trust services, including authentication, electronic signing, and data exchange. These functionalities need to be orchestrated for end-to-end service delivery (Bharosa, 2022).

This leads to a demarcation problem: how can we distinguish the different manifestations of digital wallets and their components from each other in multi-actor ecosystems? The use of vague or ambiguous terms or concepts that are not contextualised with each other is one of the causes of this lack of clarity, which can lead to operational and conceptual problems (Podsakoff, MacKenzie & Podsakoff, 2016). Moreover, the multi-actor ecosystem embedding wallets exacerbates the publicness puzzle problem (Bozeman & Bretschneider, 1994).

The objective of this paper is to contribute to solving this demarcation problem by providing both scholars and policy makers with a scientifically grounded and empirically tested taxonomy for studying wallets. Our premise is that we need a socio-technical lens for the wallet demarcation problem. According to socio-technical theory, socio-technical systems are generically defined as systems that include social (people) and technical elements (Polojärvi, 2022). Socio-technological systems also require an institutional structure that coordinates the positions, relations, and behavior of the parties that own and operate the system (Koppenjan & Groenewegen, 2005). Accordingly, the research question we answer in this article is as follows: *Which social technical design dimensions constitute a taxonomy for digital wallets found in practice?*

The contribution of this paper is two-fold. First, this is the first paper to take the socio-technical lens on digital wallets. Based on a literature review of taxonomies and wallets, we conclude that taxonomies of digital wallets that contribute to the socio-technical design are lacking, in particular for institutional design dimension. Our study contributes to the existing body of knowledge by introducing a taxonomy for digital wallets that covers this. Second, we provide practitioners and scholars with a comprehensive overview of the socio-technical design dimensions of digital wallets. This overview helps address the problem of lack of clarity in the delimitation of digital wallets. On the one hand, it facilitates scholars in their research on conceptual clarity and, on the other hand, it supports practitioners such as policymakers in choosing existing or designing new policy instruments that helps to put together the publicness puzzle (Bozeman & Bretschneider, 1994).

The remainder of this article is structured as follows. Section 2 presents the research background, zooming in on the complexity of wallets. Next section 3 presents the taxonomy development approach applied in this study. Section 4 discusses the resulting taxonomy. Section 5 concludes this paper with suggestions for further research and policy making.

2. Background: The wallet as an evolving concept

The concept of a wallet is ambiguous and is characterised by a myriad of descriptors such as 'identity', 'digital', and 'data' wallets. Synonyms for the term wallet include e-Wallet, mobile wallet, virtual wallet, online wallet, cyber wallet, electronic wallet, digital payment wallet, cryptocurrency wallet, digital identity wallet, or blockchain wallet. In this chapter, we will examine the digital wallet as a concept that has evolved over time, with technological and functional advancements occurring over several decades.

The concept “wallet” emerged in the academic literature in the late 1970s and early 1980s, initially referring to electronic financial methods by banks to enhance efficiency. Berton (1983) emphasised digital storage over cheques and cash, and Even et al. (1984) introduced electronic wallets for managing funds. This era set the stage for smart cards, progressing payment and ID digitisation. Clifford (1986) identified smart card applications beyond finance, using decentralised data storage, while Frank (1988) noted secure access and data storage. In the 1990s, wallets became decentralised, bolstered by merging PDAs[7] and smartphones with apps. The World Wide Web increased service demand, challenging old authentication. Winslett et al. (1997) argued that traditional

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

authentication was inadequate for authorisation. Thus, wallets expanded beyond finances to include digital IDs and licenses, marking a shift to digital personal data, credentials, and entitlements.

In recent academic literature, a *digital wallet* has been defined in many ways. A prevalent definition posits that a digital wallet is an electronic application accessible via smartphones or other electronic devices, facilitating rapid and secure electronic commerce transactions (Podgorelec et al., 2022a). Digital wallets are recognised as a type of electronic payment instrument that can be operated on multiple electronic platforms, including computers, laptops, and mobile phones (Shah & Rathod, 2022). These wallets offer convenience and usability in routine activities and transactions, with perceived utility being a key factor influencing users' adoption intentions.
Another perspective accentuates wallets in the digital identity sphere, empowering users with authoritative control over their identity data (Nugroho et al., 2022). Such wallets are engineered to give users governance over their digital identities, incorporating functionalities to manage and authenticate identity and other personal data (Liswanty et al., 2023a). The 'European Digital Identity Wallet' is defined as 'an electronic identification means which allows the user to securely store, manage and validate person identification data and electronic attestations of attributes to provide them to relying parties and other users of European Digital Identity Wallets, and to sign using qualified electronic signatures or to seal using qualified electronic seals' (Article 3(42) eIDAS 2024).

The ambiguity surrounding the concept of a wallet is further illustrated when zooming in on how control over personal data can be exercised. Personal Information Management Systems (Janssen & Singh, 2022b), Personal Data Stores (Kim et al., 2025a; Min & Son, 2022), and Personal Data Spaces (Lehtiniemi, 2017a) all share this objective and hence may also be regarded as manifestations of the concept of digital wallets. These developments align with the escalating datafication of society, driven by advancements in the Internet of Things (IoT) and data analysis technologies (Mejias & Couldry, 2019). The consequences of such progress include the rapid expansion of personal data and the diminishing distinction between identity and personal data, on the one hand, and non-personal data, on the other (Purtova, 2018). To allow users to exercise control over their personal information, they need exclusive online environments from which data access and sharing can be steered[8]. Illustrative examples of these advancements include IoT wallets (Lomazina et al., 2021a; Soli´c et al., 2020) and Human Digital Twins (Chen et al., 2024; Lin et al., 2024; Miller & Spatz, 2022; Zibuschka et al., 2020).

How might one navigate these wallets from a policy perspective, and under what circumstances does it apply? Determining what is encompassed and the aspects that require design consideration is crucial. A taxonomy helps to identify the 'essences in the research territory and their relationships' (Iivari J., 2007 p. 46). They are particularly crucial for both practitioners and scholars, as without a classification framework, they find it challenging to "generalise, communicate, and apply research conclusions" (Glass & Vessey, 1995 p.65). If we look at the taxonomies available in academic literature, we found (January 2025) in Scopus with the query "wallet" AND "taxonomy"[9] (in the relevant context) 38 results. A taxonomy from a policy perspective is currently absent. In the next chapter, we will explain the development of this taxonomy.

3. Research Approach: Taxonomy development process

In pursuit of the research objective, we employed the established taxonomy development methodology of Nickerson et al. (2013). This is a tested method for taxonomy development (Pawlowski & Scholta, 2023). It facilitates the integration of conceptual-to-empirical (C2E) and empirical-to-conceptual (E2C) iterations to ensure a thorough and comprehensive investigation. The approach consists of the following steps:

[8] E.g. the DGA (preamble 30) gives substance to the principle of *'bringing the algorithm to the data'* as a privacy-preserving measure when it is stated that, 'in certain situations, it could be desirable to collate actual data within a personal data space so that processing can happen within that space without personal data being transmitted to third parties in order to maximise the protection of personal data and privacy.'

[9] (ALL (taxonomy) AND ALL (wallet)) AND (LIMIT-TO (EXACTKEYWORD , "Taxonomies") OR LIMIT-TO (EXACTKEYWORD , "Taxonomy")) AND (LIMIT-TO (SUBJAREA , "COMP") OR LIMIT-TO (SUBJAREA , "ENGI") OR LIMIT-TO (SUBJAREA , "SOCI") OR LIMIT-TO (SUBJAREA , "ECON") OR LIMIT-TO (SUBJAREA , "DECI") OR LIMIT-TO (SUBJAREA , "BUSI"))

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

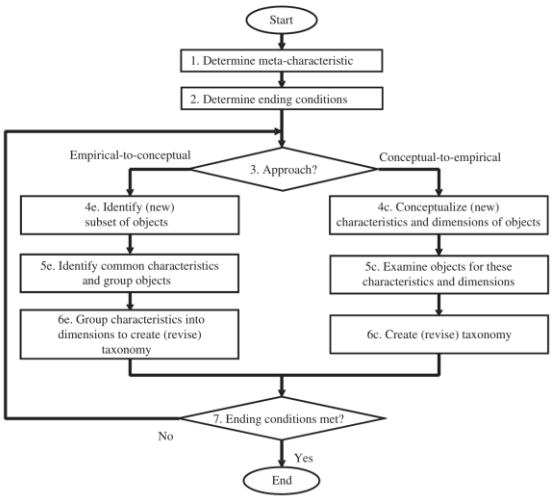

Fig. 1 The taxonomy development method (Nickerson et al., 2013)

We started by defining the purpose and expected use: differentiate digital wallets according to their characteristics for users, like practitioners, policy makers and scholars seeking to classify digital wallets. The second step was to define the objective ending conditions: The taxonomy consists of dimensions, each with mutually exclusive and collectively exhaustive characteristics. As subjective ending conditions, we followed Nickerson's recommendation: the taxonomy must be concise, robust, comprehensive, extensible, and explanatory (p. 344).

The initial iteration of the E2C encompassed a comprehensive examination of the design specifications relevant to the EUDI wallet. This examination was informed by European legislation, namely eIDAS 2.0, GDPR[10], and DGA[11], as well as Dutch legislation, ARF (which includes acknowledged standards such as the Verifiable Credentials Data Model v1.1), and Large Scale Pilots[12]. Seen through a socio-technical lens, we have concluded from this analysis that digital wallets contain the aspects of actors, capabilities, data, and infrastructure (including devices). We have delineated the following dimensions: 1- Identity model, 2- Guaranteed data, 3- Wallet provider, 4- Trust services, 6- Supervision, 7- Jurisdiction (territoriality), 8- Jurisdiction (organisation) and 9- Capabilities.

The objective of the second iteration was to perform an E2C analysis of a comprehensive set of existing digital wallets, utilising the dimensions established in the first iteration. The set compilation was informed by the description provided in Table 1 and three previous assessments by independent third-party entities. These entities were SIVI (88) [13], MyData (35) [14], and DUE (101) [15], amounting to a total of 224 digital wallets. These objects were analysed based on actors, capabilities, data, and infrastructure themes. The analysis was based on publicly accessible descriptions of the wallets, complemented by qualitative insights from interviews conducted during the initial inventories. The results of this iteration were a list of 13 characteristics on the dimension capabilities and adding the dimension transaction initiative, sector, and jurisdiction (organisation type). In addition, the characteristics of the first iteration have been supplemented.

The source material utilised in the second iteration offered significant insight into capabilities, though it provided limited information regarding the technology employed. For instance, cryptocurrency wallets facilitate crypto transactions. The understanding of the foundational technology, blockchain, has been extracted from alternative sources. Therefore, the third iteration (C2E) comprised an analysis of the academic literature based on Table 1, and in this iteration, the Applicability and Data exchange initiative dimensions were added.

Tab. 1 Literature Taxonomy and Wallet

Query	Literature selected on relevance
'taxonomy' AND 'wallet'(including e-wallet, electronic payment wallet, cryptocurrency wallet, identity wallet, IoT wallet)	(Amard et al., 2024; Degen & Teubner, 2024; Kersic et al., 2023a; Lama, 2022; Larsen et al., 2023; Liswanty et al., 2023; Lomazina et al., 2021b; Naik & Jenkins, 2020; Olsen et al., 2011; Podgorelec et al., 2022b; Sahmim et al., 2019; Sampath et al., 2022; Shah & Rathod, 2022; Stodt et al., 2024; Teng & Khong, 2021)

In the fourth iteration (C2E), we build on the technical insights of iteration 3. In this iteration, we used a selection of academic literature based on table 2, and in this iteration, the Platform dimension was added.

Tab. 2 Literature platform and infrastructure

Query	Literature selected on relevance
'taxonomy' AND 'digital platform', 'taxonomy' AND 'digital infrastructure' 'taxonomy' AND 'blockchain'	(Blaschke et al., 2019; da Silva Neto & Chiarini, 2023; Heurix et al., 2015; Rizk et al., 2018)
'digital platform', 'digital infrastructure', 'blockchain', 'digital ecosystem'	(Addo, 2022; Berndsen & Wandhöfer, 2020; Cammaerts & Mansell, 2020; de Reuver et al., 2020; Goertler et al., 2023; Hein et al., 2020; Lips, 2023; McIntyre et al., 2021; Ozalp et al., 2022; Rohn et al., 2021; Steffen et al., 2023; Susha et al., 2023)

The **fifth iteration** (C2E) focused on emerging concepts such as data spaces (e.g., eHealth data spaces[16]) and data intermediaries as described in the DGA[17]. Although these developments are still in progress, their inclusion allowed the identification of forward-looking characteristics and trends. The results of this iteration were adding the dimensions Data Intermediation.

Tab. 3 Literature data space and data intermediary

Query	Literature selected on relevance
Data Space	(Hägglund et al., 2024; Kim et al., 2025b; Lehtiniemi, 2017b; Marcus et al., 2022; Raab et al., 2023; Stellmach et al., 2022)
Data intermediary	(Bühler et al., 2023; de Rosnay & Stalder, 2020; Janssen et al., 2020; Janssen & Singh, 2022a, 2022c; Julia Hilberg, 2023; Micheli et al., 2023)

Digital wallets are, by their nature, only accessible to the user of the wallet. To analyse the implemented and working digital wallets and test our results so far, we chose the digital wallets that are accessible to the researcher. In the **sixth iteration** (E2C) we chose wallets provided by banks (ABN AMRO App using Apple Pay[18] and Triodos Mobiel Bankieren app[19],) and in the **final iteration** we chose wallets provided by the Belgium government (Itsme[20]) and Dutch government (Mijnoverheid.nl[21], and Mijn verzekeringsbericht[22]). These digital wallets were analysed to capture minute details of their functionalities, interfaces, and underlying architecture. No new dimensions or characteristics have emerged.

At each iteration, the characteristics and dimensions were validated, modified, or extended according to the findings of the data sets. This iterative process continued until the end objective conditions were met. The first version of the taxonomy yielded 83 characteristics in 20 dimensions. As subjective ending conditions, we followed Nickerson's recommendation: the taxonomy must be concise, robust, comprehensive, extensible, and explanatory (p. 344). Because we did not find 83 characteristics in 20 dimensions concise, we dropped the dimensions with characteristics related to functionalities as derived from the empirical analysis. We have renamed this dimension to one dimension functionality. The final list consists of 47 characteristics in 14 dimensions. These results are explained in more detail in the next section.

4. Result: Proposed taxonomy of digital wallets

In this section, we introduce the proposed taxonomy for digital wallets. This taxonomy comprises 47 characteristics spread over 14 dimensions. Each dimension embodies an aspect or perspective of the digital wallet phenomenon. A characteristic delineates the potential values, derived from the analysis of the objects, that a dimension may assume concerning a digital wallet.

Dimension	Characteristics						
1-Identity model	1.1-centralised	1.2-decentralised	1.3-Federated	1.4-Self-sovereign			
2-Guaranteed data	2.1-non-EAA	2.2-EAA	2.3-QEAA	2.4-PuB-EAA			
3-Wallet provider	3.1-Member State	3.2-mandated organisation	3.3-recognised organisation	3.4-not recognised organisation			
4-Trust services	4.1-qualified	4.2-not qualified					
5-Data Intermediation	5.1-neutral DISP	5.2-Not-neutral DISP					
6-Supervision	6.1-present	6.2-not present					
7-Jurisdiction (territoriality)	7.1-only national territory	7.2-inside EU territory	7.3-outside EU territory				
8-Jurisdiction (organisation)	8.1-public	8.2-private	8.3-hybrid				
9- Funding model	9.1-public	9.2-privat	9.3-hybrid				
10-Applicability	10.1-open	10.2-brand open	10.3-bank-open	10.4-closed	10.5-semi-closed		
11-Functionality	11.1-high functionality	11.2-low functionality					
12-Data type	12.1-Regular personal	12.2-Special categories personal	12.3-Criminal records	12.4-Credential	12.5-Pseudo-nymized	12.6-Non-personal	12.7-Anonymous
13-Data exchange initiative	13.1-on initiative wallet user	13.2-on request relying party	13.3-at the initiative of the source				
14- Platform	14.1-Centralised	14.2-Decentralised	14.3-Distributed				

Fig. 2 Proposed taxonomy of digital wallets

In the subsequent sections of this chapter, the taxonomy will initially be presented, followed by an elucidation of each dimension alongside its corresponding characteristics. The numbering within the taxonomy aligns with that in the explanatory notes.

1- Identity Model

An identity model refers to how personal identity data are managed and shared. The similarity is that they all aim to manage and use them to provide access to services or systems. They distinguish themselves in the aspects managed by the issuer, user control level, privacy protection, single point of failure, trust by relying party, interoperability, and technology. An overview is explained in Annex 1. This taxonomy distinguishes the dimension Identity model between **centralised, decentralised, federated, and self-sovereign identity**.

2- Guaranteed data

An attribute can be defined as information that describes a certain quality, right, or permission of an identified subject (natural or legal person) or object. For a relying party that wants to rely on the accuracy of the data, guarantees concerning at least the following elements are central: (1) the accuracy of the identified subject and (2) the accuracy of the value of the attribute, and (3) the accuracy of the relationship between the identified subject and the attribute, and (4) the identity of the issuer. Electronic Attestation of Attributes (EAA) refers to the process of electronically verifying and confirming attributes of a subject. If an EAA is provided by a Qualified Trust Service Provider (QTSPs), it is called a Qualified Electronic Attestation of Attributes[23]. EAA issued by or on behalf of a public body responsible for an authentic source. A PuB-EAA is an EAA that is legally trusted by default[24]. For this taxonomy, we distinguish between **non-EAA, EAA, QEAA,** and **PuB-EAA**.

3- Wallet provider

A digital wallet provider facilitates the provision of a digital wallet to the end user. A provider can be a public or a private organisation whose location can, in principle, be worldwide. A provider can be part of a group (e.g. Google, Apple) or an independent organisation that provides its services to others. To increase trust in these parties, the eIDAS (2024) novel certification framework by the Member States to recognise providers (Article 5c).

[23] https://github.com/eu-digital-identity-wallet/eudi-doc-architecture-and-reference- framework/blob/v1.4.0/docs/arf.md (section 3.5)

[24] https://github.com/eu-digital-identity-wallet/eudi-doc-architecture-and-reference- framework/blob/v1.4.0/docs/arf.md (section 3.6)

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Consequently, until recognition is granted, all digital wallet providers are classified as 'not recognised.' Upon implementation, three variants of EUDI Wallet Providers emerge: those instituted by Member States, those mandated by Member States, or those recognised by Member States, all of which provide the EUDI Wallet for end users[25]. For this taxonomy, we distinguish the dimension Wallet provider between **Member State, mandated organisation, recognised organisation**, and **not recognised organisation**.

4- Trust services

This dimension focuses on a trust service provider's level of trustworthiness. A trust service is defined as 'an electronic service normally provided for remuneration that consists of (a) the creation, verification, and validation of electronic signatures, electronic seals, or electronic time stamps, electronic registered delivery services and certificates related to those services, or (b) the creation, verification, and validation of certificates for website authentication; or (c) the preservation of electronic signatures, seals, or certificates related to those services' (eIDAS 2024 article 3(16).). Article 3 (17) defines a 'qualified trust service' as a trust service that meets the applicable requirements set out in the eIDAS Regulation. For this taxonomy, we distinguish between a **qualified trust service provider** and a **non-qualified trust service provider**.

5- Data Intermediation Services Provider

The emergence of the concept of inclusive data governance[26] stems from broader discussions of data ethics and human rights within academic literature and international organisations, among others. It aims to promote equitable, ethical, and participatory data management, considering various stakeholders' needs, rights, and perspectives. Data Intermediation services aim to give substance to this concept, whereby it should be noted that 'at the current time the landscape is still dynamic, and governance practices have not yet crystallised' (Centre et al., 2023). The DGA, article 2(11) defines 'data intermediation service' as 'a service which aims to establish commercial relationships for data sharing between an undetermined number of data subjects and data holders on the one hand and data users on the other, through technical, legal, or other means, including to exercise the rights of data subjects in relation to personal data'. Data Intermediation Services Providers include data cooperatives, data trusts, data unions, data marketplaces, and data sharing pools (Centre et al., 2023). The DMS draws up rules in Article 12, among other things, to safeguard the neutral position of that provider. For example, these rules provide restrictions on use, clarity about fees, etc. For this taxonomy, we distinguish between a **neutral DISP** (complying with the set DGA rules) and a **non-neutral DISP** (not complying with the set DGA rules).

6- Supervision

The deployment of independent and mandated agents is frequently employed to promote cooperation and trust among participants within an ecosystem[27]. These agents are entrusted with the responsibility of facilitating the integration of other participants into a trust-based system. Their duties include evaluating compliance with established regulations and, when required, enforcing adherence to these standards (encompassing admission, recognition, and enforcement processes). The existence of such supervisory entities ensures the effective operation of the ecosystem. For this taxonomy, we distinguish, therefore, between a **mandated supervisor present** and **no mandated supervisor present**.

7- Jurisdiction (territoriality)

A fundamental legal principle dictates that cooperating entities adhere to agreements, and such adherence can be enforced in the event of noncompliance. The commitment to the agreements made is paramount to this principle (*pacta sunt servanda:* "agreements must be kept")[28]. According to (Ryngaert (2008), jurisdiction is understood as individuals or entities' obligation to adhere to state regulations. Within international law, jurisdiction denotes the authority and capacity of a state to enact legislation, implement enforcement measures, and administer justice within a specified territory or concerning specific individuals or entities. Various principles of international and domestic law define a state's jurisdiction.

The primary foundational principle is the principle of territoriality, in which a state possesses jurisdiction over events, actions, or individuals within its territory (Ryngaert, 2008). Jurisdiction is further established through international treaties, as exemplified by the European Union. Given the simultaneity of these jurisdictional forms (territorial and treaty-based), an entity may encounter national and European regulations. Therefore, this taxonomy distinguishes between a digital wallet ecosystem that operates **only in national territory, inside EU territory**, and **outside EU territory.**

8- Jurisdiction (organisation type)

Digital wallets are made available by both public and private organisations. These organisations are distinguished by their purpose, ownership structure, and financing methods. Public organisations primarily prioritise the public interest, whereas the commercial interests of their owners drive private organisations. Such distinctions also

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

impact the regulatory framework to which these entities are subject. Public law governs the relationships between government agencies and citizens and addresses the internal organisation of the government, intending to safeguard public interest and maintain public order. On the contrary, private law refers to the legal relationships between private entities.

The EUDI wallet represents a digital ecosystem that can be implemented jointly by public and private entities. Public entities within this framework are subject to public law, whereas private entities comply with private law. This regulatory discrepancy is evident, for example, in the guidelines concerning the procurement of services from third parties, as delineated by European competition law. Furthermore, both public and private organisations are engaging in innovative hybrid organisational forms by collectively owning an entity dedicated to providing digital wallets for use by citizens and businesses. For this taxonomy, we distinguish between **public, private**, and **hybrid** organisations involved in the wallet ecosystem.

9- Funding model

Introducing a digital wallet requires significant investment in development and operation. Governments will finance this from taxes, while for private actors in the digital ecosystem, this will often be an investment that must be compensated for to achieve an acceptable return on investment (ROI). This funding model relates to the business model for digital wallets and covers investments in development and operation on the one hand and monetisation of value transfer. Public business models are aimed at creating value for society, are publicly funded, and are aimed at cost reduction rather than profit maximisation. On the other hand, private business models are aimed at creating financial profit for shareholders or owners, have private financing, and are competitively driven by innovation, cost reduction, or customer loyalty. Hybrid models in which public and private parties work together combine characteristics of both domains. For this taxonomy, we distinguish the dimension funding model between **public**, **private**, and **hybrid**.

10- Applicability wallet

An organisation often provides digital wallets as an extension of their business processes to facilitate personalised transactions with the wallet user. For the retail sector and related payments, Levitin (2018) differentiates digital wallets into "open", "brand-open," "bank-open," "closed", and "semi-closed", concerning payments and acceptance. These differ in varying degrees of freedom of use for wallet users, vendor adoption, and interoperability between wallets. A similar distinction can also be found in other sectors where digital wallets are used. Because these wallets are also often provided as an extension of business processes, they will be more likely to support the personal data set, user interface, business rules, and functions required for that specific business process.

Examples of industries with sector-specific digital wallets include: Finance (ING Mobiel Bankieren App[29]), Health (SelfPass[30]), Real Estate (Zorgeloos Vastgoed[31], Property Wallet[32]), Education (Eduwallet[33]), Media (Datakluis[34]), Government (Digid[35]), Rental (Qii[36]), Telecom (Finacle[37]), Energy (EnergieID[38]), Agrifood (Agri-Wallet[39]) and Travel/Tourism (GrabPay[40]). These sector-specific digital wallets exist alongside more generically applicable ones, such as the EUDI wallet, which will offer identification, authentication, and a limited set of (verified) personal data. We follow the characteristics set by Levitin (2018) and generalise them to other digital wallets in the explanatory descriptions.

Tab. 5 Applicability wallet

10	System	Explanation	Example
1	Open	Can be used for managing personal data at a wide range of actors and often supports multiple capabilities like signing, sealing, sharing, storage, and so on. This wallet is also free of any brand or industry restrictions.	EUDI wallet
2	Brand-open	Developed and managed by a specific brand, but offers the ability to share data with other companies, often integrated into the brand's ecosystem but not limited to use within that ecosystem.	MyQii app
3	Bank-Open	Integrated with the user's bank account, it can be used to make payments from a variety of actors, like an open wallet, and often also	ING app

		supports bank transfers and other banking services.	
4	Closed	Can only be used with a specific actor or group of actors that are part of the same ecosystem and has no interoperability with other digital wallets or networks outside of its own system.	MijnOverheid.nl
5	Semi-closed	Can be used with multiple actors, but only within a specific network or group of contracted actors, but has limited interoperability with other systems.	Vidua Vastgoed

For this taxonomy, we distinguish the dimension **applicability** between **open, brand-open, bank-open, closed, and semi-closed** digital wallets.

11- Functionality wallet

The results of the digital wallet analysis showed a set of functionalities that can be part of a digital wallet. The first group relates to Identification and Authentication Management (management of identification, authentication, authorisation, representation, and consent). The second group relates to Customer Relation Management (management of preference, loyalty, and contact). The third group relates to Transactions (order service, execution transactions, payment service, and monetise data). Finally, the fourth group relates to additional services (digital diary for diabetes, personal finance management, lifestyle management, Know Your Customer check, billing, and payment request).

Digital wallets can support one or more of these functionalities depending on the intended use. This distinguishes between low-functionality digital wallets (limited to a few functionalities) and high-functionality digital wallets (supporting multiple functionalities). DigID (limited to identification, authentication, and representation) is an example of a low-functionality digital wallet. Examples of high-functionality digital wallets can be found in the Asia-Pacific region. WeChat Pay[41] and Alipay[42] (China), GrabPay[43] (Singapore), and Kakao Pay[44] (South Korea) combine various functionalities such as payment, order service, and execute transactions into multi-functional digital wallets. For this taxonomy, we distinguish the dimension functionality wallet between **high-functionality** and **low-functionality** digital wallets.

12- Data Type

Within the data type dimension, we distinguish between different forms of (personal) data. The starting point here is the European context, in which this distinction has been elaborated in the GDPR. For this taxonomy, we distinguish for the dimension data type between:

Tab. 6 Data Type

12	Data Type	Meaning:
1	Regular personal data	Any information relating to an identifiable or identified natural person. (Article 4(1) GDPR)
2	Special categories Personal Data	personal data concerning a person's racial or ethnic origin, political opinions, religious or philosophical beliefs, trade union membership, health, sex life or sexual orientation, genetic data, and biometric data.
3	Criminal record data	are data relating to criminal convictions and offences or to security measures related to them.
4	Credentials	personal data as a digital proof of qualities, training, or experience that make you suitable for doing something[45]
5	Pseudonymised Data	Identifying data with a certain algorithm is replaced by encrypted data (the pseudonym) so that someone's identity can be concealed. Because a link can be established between pseudonymised data and identifying data, pseudonymised data is full personal data. (defined in Article 4(5) GDPR)
6	Non-personal data	Any data that is not personal data.
7	Anonymous Data	Non-personal data, as these data cannot be traced back to an identified or identifiable natural person.

13- Data Exchange Initiative

The dimension data exchange initiative refers to the entity that is undertaking the initiative to insert, access, or extract data from the wallet. A transaction may necessitate this within the framework of an agreement or in adherence to a legal obligation. Furthermore, data exchanges are increasingly occurring autonomously, without

[41] https://pay.weixin.qq.com/index.php/public/wechatpay_en/

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

the necessity for direct human intervention. This phenomenon results from the growing datafication (encompassing personal data generated by sensors (IoT)), the deployment of algorithms that autonomously ascertain with whom and when data exchange transpires, and contactless data exchange (embracing Near Field Communication (NFC), Radio Frequency Identification (RFID), Bluetooth, Wi-Fi Direct, and Ultra-Wideband (UWB)). These systems are not identified as independent actors yet, but rather as technological instruments employed on behalf of a human actor. For this taxonomy, we distinguish for the dimension data exchange initiative between:

Tab. 7 Data Exchange Initiative

13	Initiative	Meaning:	Example
1	on initiative wallet user	The wallet user obtains data from an external source or provides/presents data to a relying party.	The user needs the last income data.
2	on request of the relying party	The relying party obtains data from the digital wallet, direct from the internal storage, or indirectly from the external source with the consent of the wallet user.	The user buys a house and provides data to the broker.
3	at the initiative of the source;	The source (human actor or systems) can provide data to the digital wallet	Automatically send when there is an update in the source.

14- Platform

A digital platform plays a central role in data exchange between actors. For this taxonomy, we distinguish for the dimension platform between centralised, decentralised, and distributed. Table 10 provides an overview.

Tab.10 Platform

Platform	is characterised by:
Centralised	All data and control are managed by a single entity or authority, leading to a dependency on a central system for operations and decision-making (Kersic et al., 2023b). They often have a single point of failure, making them vulnerable to security breaches and downtime if the central entity is compromised.
Decentralised	They distribute data and control across multiple nodes or entities, reducing the need for a single central authority for management and decision-making. They emphasise self-custodial and self-sovereign management of digital identities, enabling users to control their identifiers and related data without centralised entities (Kersic et al., 2023b).
Distributed	They involve a network of interconnected nodes that work together to achieve a common goal, sharing data, and processing tasks across multiple nodes in a peer-to-peer fashion (Sahmim, 2019). No single point of control or failure exists as the network operates collectively, improving resilience and scalability (Sahmim et al., 2019).

5. Conclusions and future research

This paper addresses the lack of clarity in the demarcation of digital wallets by developing a taxonomy for digital wallets. The demarcation problem amplifies the struggle of private and public service providers in their journey to develop and implement digital wallets. The research question we answered in this paper is: Which social-technical design dimensions constitute a taxonomy for digital wallets found in practice?

We first took the socio-technical lens on digital wallets to answer this question. We applied the methodological theory of Nickerson et al. (2013) to develop a taxonomy for digital wallets. This is a tested method for providing practitioners and researchers with a comprehensive overview of digital wallets' social and technical design dimensions.

The taxonomy developed in this study contains 14 dimensions and 47 variables that characterise a wallet. Our study contributes to the existing body of knowledge by introducing a taxonomy for digital wallets that covers the socio-technical design dimensions. Additionally, it facilitates scholars in their research on conceptual clarity, and, on the other hand, it supports practitioners such as policymakers in choosing existing or designing new policy instruments that support the launch of wallets.

Given the social impact of these wallets, more research is encouraged. We identify three main research directions. First, the proposed taxonomy can be further validated and developed by applying it to other empirical cases across the globe. Second, applying the taxonomy could help identify governance challenges for digital wallets. Studies looking into the governance of wallets are lacking, mainly focusing on safeguarding public values. What policy instruments and regulatory tools can effectively address specific challenges? Finally, we applied the

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

methodological theory of Nickerson to develop a taxonomy for digital wallets. We have combined this methodology with socio-technical design theory for a taxonomy-driven digital wallet design approach. We encourage the further development of the theory of taxonomy-driven policy instrument design.

Unleashing Public Sector Innovation: Exploring the Impact of Big Data Analytics and Value-Driven Capabilities on Digital Governance

Sulemana Bankuoru Egala [a*], *Abdul-Hamid Sokun Alhassan*[a], John Asibuo Boakye[a]

[a] Faculty of Information and Communication Technology, Department of Informatics, SD Dombo University of Business and Integrated Development Studies, Wa, Ghana. sbegala@ubids.edu.gh*; ORCID; 0000-0002-1070-5480

Submitted: 31 January 2025, Revised: 26 March 2025, Accepted: 21 April 2025, Published: 21 May 2025

Abstract. Big data analytics (BDA) is fast revolutionizing circular economy being driven by the avalanche of data. In public governance, harnessing the value-driven opportunities of BDA has been challenging studied to improve resource allocation, decision-making, and openness and accountability but, with little attention in existing literature. Through the lens of the task technology fit theory, this study examines how big data analytics and value-driven capabilities improve public sector digital governance innovation and performance. The study leveraged PLS-SEM and collected data from 310 staff of public sectors institutions in Ghana. The study found that, task complexities, value-driven capabilities, data quality, organizational support and analytical literacy have significant impact on public sector innovation. this relationship is not however moderated by digital governance maturity. Moreover, public sector innovation was found to influence digital governance performance. The study underscores how data-driven innovations could be leveraged to improve service delivery and citizen participation in digital governance. This study outlines best practices for public sector organizations to effectively utilize big data, enhancing decision-making and governance, and fostering trust and performance in the digital era.

Keywords. Public sector innovation, big data, analytics, digital governance, task technology fit
Research paper, DOI: https://doi.org/10.59490/dgo.2025.976

1. Introduction

Big data analytics (BDA) and artificial intelligence (AI) have emerged as transformative tools in reshaping public governance, enabling governments to analyze large, diverse datasets, uncover actionable insights, and optimize public service delivery. These technologies have the potential to address pressing societal challenges, enhance transparency, and foster citizen-centric governance models (Cingolani, McBride, & Hammerschmid, 2022; Curry et al., 2021). Initiatives like the European Data Space exemplify this promise by creating unified frameworks for data sharing and analysis, with an estimated economic contribution of €2.5 trillion annually by 2030, including benefits for public administration (European Commission, 2022). Similarly, in Kenya, integrating AI into healthcare has improved resource allocation and reduced maternal mortality rates by 15% over five years, showcasing the measurable impact of BDA on governance and service delivery (Agolla, 2015).

At its core, BDA involves collecting, processing, and analyzing vast datasets to identify patterns, correlations, and actionable insights (Mach-Król & Hadasik, 2021). In public governance, this enables predictive analytics for urban planning, disaster response optimization, and enhanced citizen engagement (Urs, Nisioi, & Roja, 2023). However, the successful implementation of BDA requires more than technical integration. It demands alignment with organizational and contextual factors, including value-driven capabilities, data quality, and analytics literacy—all essential for ensuring that technology adoption aligns with ethical, transparent, and citizen-centric principles. For instance, the Netherlands successfully combined participatory governance models with BDA, increasing public trust in municipal services by 25% over three years (Mariani & Mortati, 2024). Furthermore, organizational support and task complexities play a pivotal role in determining whether BDA tools are effectively utilized to address governance challenges.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Despite its potential, the public sector in most developing economies faces several challenges in adopting BDA effectively. Fragmented data infrastructures, insufficient technical expertise, and concerns over data privacy are significant barriers (Gupta et al., 2023; Egala & Afful-Dadzie, 2022). For example, over 60% of public sector organizations in the EU identify interoperability issues as a major obstacle to achieving data-driven innovation (European Commission, 2022). This is even dire in most developing economies where the issues go beyond interoperability to low literacy on BDA (Shah, 2019). This raises ethical concerns, including algorithmic bias and risks of mass surveillance, further complicate the adoption of BDA, threatening public trust and accountability. In contrast, the private sector has demonstrated considerable success in leveraging BDA to drive innovation and efficiency, leaving public institutions at risk of falling behind due to bureaucratic inertia and insufficient digital governance maturity (Dorasamy, 2021).

Existing research highlights the transformative potential of BDA in enhancing public governance. Gupta et al. (2023) for instance, emphasizes its role in promoting sustainability, while Palumbo et al. (2023) examine how open innovation frameworks can modernize public services. Urs et al. (2023) underscore the importance of leadership in fostering digital transformation, and Bwalya (2018) explores the role of e-government initiatives in developing economies. However, these studies often focus on isolated technical frameworks or case studies, leaving significant gaps in understanding the interplay between BDA and key variables such as task complexities, data quality, organizational support, and analytics literacy. Additionally, the moderating role of digital governance maturity, a critical factor influencing the success of technology adoption remains underexplored.

To address these gaps, this study synthesizes big data analytics with value-driven capabilities to investigate how they enhance public sector innovation by fostering efficiency, improving decision-making, and aligning governance with societal values. The research explores the mechanisms through which BDA drives innovation, emphasizing the importance of task complexities, data quality, and organizational support in enabling meaningful outcomes. Additionally, it examines how digital governance maturity moderates these relationships, enhancing public sector innovation and governance performance.

The objectives of this study are twofold: (1) to investigate how big data analytics capabilities influence public sector innovation and (2) to analyze the impact of value-driven capabilities, data quality, and organizational support on ethical and effective governance. By addressing these objectives, this research aims to bridge critical gaps in theory and practice, providing actionable recommendations for policymakers and practitioners. The study seeks to propose a holistic framework that integrates these elements to foster transparency, efficiency, and citizen-centric solutions. Ultimately, the convergence of big data analytics and value-driven governance represents a transformative opportunity for the public sector to achieve sustainable innovation. However, addressing systemic challenges, such as fragmented infrastructure, data privacy concerns, and insufficient digital governance maturity, remains critical. By advancing the understanding of these interactions, this study contributes to the ongoing discourse on digital transformation, offering a roadmap for fostering equitable and impactful public sector innovation particularly in developing economies.

2. Conceptual foundation and hypothesis formulation

2.1 Task technology fit theory

The Task-Technology Fit Theory (TTFT) provides a theoretical foundation for evaluating the alignment between technology, task requirements, and user capabilities. According to TTFT, the effectiveness of a technology depends on how well it supports the specific tasks it is intended to enhance (Goodhue & Thompson, 1995). The theory posits that when a technology is appropriately tailored to address the complexities, interdependencies, and requirements of tasks, it leads to improved performance outcomes (Abelsen et al., 2021). A strong task-technology fit ensures that the capabilities of the technology align with organizational goals and individual competencies, resulting in enhanced innovation and efficiency (Isaac et al., 2019).

In the context of public governance, the integration of big data analytics capabilities and value-driven frameworks has the potential to transform decision-making processes, enhance transparency, and foster citizen-centric governance. TTFT provides a robust framework to analyze the interplay between task complexities, data quality, organizational support, and analytics literacy in influencing the adoption and effectiveness of big data analytics (BDA) technologies (Abelsen et al., 2021). Furthermore, the maturity of digital governance systems acts as a moderating factor, influencing how these variables contribute to public sector innovation and digital governance performance.

This study leverages TTFT to explore how public sector organizations can harness BDA tools to meet complex governance challenges while ensuring alignment with ethical and societal values. The theory guides the investigation of how task characteristics, organizational factors, and technological readiness interact to drive innovation and improve governance outcomes. By integrating TTFT into the analysis, this research emphasizes the importance of aligning technical capabilities with organizational and societal priorities for achieving sustainable innovation.

2.2 Big data analytics task complexities effect on public sector innovation

Big data analytics, characterized by the 5Vs (volume, variety, velocity, veracity, and value), presents unique analytical challenges due to its scale, diversity, and dynamic nature (Sreenivasan, 2017). Task complexity examines the regulatory, stakeholder and technical challenges confounding big data. These inherent complexities can act as catalyst for innovation, particularly in the public sector, where data-driven insights can transform service delivery, policymaking, and citizen engagement. For instance, when governance tasks involve high complexity, such as managing large, heterogeneous datasets, navigating regulatory constraints, or addressing multi-stakeholder demands, traditional methods may prove inadequate, creating a misfit that necessitates innovative solutions (Abelsen et al., 2021). Gupta et al. (2023) contends that, BDA capabilities help bridge this gap by enabling advanced data processing, predictive insights, and real-time decision-making, thus improving task-technology alignment. However, excessive complexity without sufficient organizational support or analytics literacy can hinder innovation. Effectively managing and analyzing these complexities is crucial for implementing transformative initiatives such as smart city solutions, advanced healthcare systems, and adaptive environmental policies (Kuru,2020). Existing studies underscore the importance of data-driven decision-making in enhancing transparency and accountability within public administration (Alexopoulos & Janssen, 2020; Bibri, 2020). The ability to leverage BDA effectively is significantly influenced by task complexities coupled with low digital infrastructure, data governance frameworks, and skilled personnel. This influence of BDA complexities is supported by research emphasizing organizational context and digital transformation as key enablers of public sector innovation (Gil-Garcia et al., 2020). Studies also highlight the importance of digital governance frameworks for effective data utilization and public sector innovation (Janssen et al., 2020; Chhetri et al., 2021). Following these discussions, we hypothesize that:

H1: Big data analytics task complexities will significantly influence public sector innovation.

2.2 Big data analytics capabilities effect on public sector innovation

BDA capabilities, encompassing the technical infrastructure, analytical skills, and organizational processes necessary to effectively handle complex datasets, are crucial drivers of innovation, particularly within the public sector (Janssen et al., 2020). It measures the technical capabilities and assesses the predictive decision-making capabilities of big data. These capabilities enable organizations to understand citizen needs, identify emerging trends, and develop solutions to complex challenges. Existing research highlights the imperative of robust data governance and management practices in cultivating innovation and agility within public sector organizations (Janssen et al., 2020). Moreover, a data-driven culture and effective leadership are essential for harnessing the potential of BDA to drive organizational transformation and innovation in the public sector (Arshad et al., 2024). However, the ability of public sector organizations to effectively leverage BDA capabilities is significantly influenced by their existing digital infrastructure, data governance frameworks, and overall digital maturity (Waqar & Paracha, 2024). Organizations with more mature digital governance structures, characterized by robust data management practices, skilled personnel, and clear data strategies, are better positioned to harness the full potential of BDA for innovation. This moderating role of digital maturity is supported by research emphasizing the importance of organizational context and digital transformation in public sector innovation (Ndou, 2020). Extant research further underscores the significance of robust data governance frameworks in facilitating responsible AI implementation within the public sector, a critical component of contemporary digital governance (Leslie et al., 2021). Following these discussions, we hypothesize that:

H2: Big data analytics capabilities will significantly influence public sector innovation;

H2a: Digital governance maturity will moderate between big data capabilities and public sector innovation.

2.3 Effect of value-driven capabilities on public sector innovation

Value-driven capabilities in BDA represent the organizational capacity to ethically and transparently align technological applications with societal priorities, ensuring data-driven initiatives benefit citizens and communities (Mittelstadt et al., 2016). This ethical and societal alignment is crucial for translating raw data into public value and driving meaningful public sector innovation. Specifically, BDA value-driven capabilities influence public sector innovation by enabling organizations to derive actionable insights, align analytical efforts with strategic goals, and measure outcomes. Existing research underscores the significance of responsible data use and ethical considerations in optimizing the benefits of data-driven initiatives for citizens (Hagendorff, 2020). Moreover, robust data governance frameworks and effective management practices are essential for unlocking the value of data in the public sector (Brous & Janssen, 2020). By integrating stakeholder engagement and focusing on outcomes that align with societal goals, public sector organizations can leverage these value-driven capabilities to drive sustainable innovation and better serve their communities. Following these discussions, we hypothesize that:

H3: Big data analytic value-driven capabilities will significantly influence public sector innovation.

2.4 Effect of big data quality on public sector innovation

Data quality, encompassing dimensions like accuracy, completeness, consistency, and timeliness, is foundational

for effective data utilization and informed public sector decision-making (Egala & Afful-Dadzie, 2022). Thus, measuring the intrinsic and assessing the contextual accuracy, consistency, security and relevance of the public data. In the context of big data, these core dimensions are amplified, necessitating considerations of believability, interpretability, and accessibility (Batini et al., 2016). High-quality big data is pivotal for driving public sector innovation by providing reliable and actionable insights that inform policy decisions, resource allocation, and service delivery. Conversely, poor data quality undermines these efforts, leading to flawed insights and ineffective policies. Existing research underscores the critical role of data quality in various facets of public sector operations. Robust data quality management frameworks are essential for effective data utilization and innovation in public organizations, particularly in open government data initiatives, where high-quality data is paramount for fostering citizen trust (Kalampokis et al., 2020). The increasing reliance on real-time data in public services, such as smart city applications, further highlights the imperative of timely and accurate data for effective service delivery (Bibri, 2020). Moreover, extant studies emphasize the importance of effective data management practices, including rigorous data quality control, for informing data-driven decision-making and public service delivery (Janssen et al., 2020; Zuiderveen Borgesius et al., 2020). Following these discussions, we hypothesize that:

H4: Big data quality will significantly influence public sector innovation

2.5 Effect of organizational support on public sector innovation

Organizational support, encompassing leadership advocacy, resource allocation (financial, technological, and human), and a collaborative culture, is fundamental for public sector innovation, especially given complex societal challenges (Amabile & Pratt, 2016). This supportive environment fosters experimentation, risk-taking, and knowledge sharing, all of which are crucial for driving innovation within public organizations. While pioneering research investigated the general relationship between organizational support and various organizational outcomes, including innovation (Anderson et al., 2014), recent studies have narrowed their focus to examine the specific roles of leadership and organizational culture in cultivating digital innovation within public sector organizations (Nadkarni & Prügl, 2021; Kraus et al., 2022). Notably, the efficacy of organizational support in driving digital innovation is substantially augmented by the maturity of digital governance frameworks. Mature digital governance, characterized by strategic alignment, robust data management, and active citizen engagement, provides the necessary framework for effectively channelling organizational resources toward innovation (Udoh, 2024). The maturity of digital governance frameworks facilitates alignment with public needs, enhances transparency, and cultivates a data-driven culture, thereby ensuring that organizational support yields meaningful outcomes. This moderating role of digital governance maturity is corroborated by extant research, which underscores the significance of organizational context and digital transformation in driving public sector innovation (Ndou, 2020). Furthermore, existing studies highlight the importance of developing digital skills and capabilities within public sector organizations to facilitate successful digital transformation and innovation (Janssen et al., 2020). Following these discussions, we hypothesize that:

H5: Organizational support will significantly influence public sector innovations

H5a: Digital governance maturity will moderate between organizational support and public sector innovation

2.6 Effect of analytics literacy on public sector innovation

Analytics literacy, entails the ability to effectively interpret, analyze, and communicate data insights using analytical tools, is increasingly crucial for data-driven decision-making and innovation (Chen et al., 2012). Analytics literacy empowers individuals to transform raw data into actionable knowledge. Analytics literacy is a critical driver of public sector innovation, enabling data-informed solutions. While earlier work provided valuable perspectives (Magakwe, 2025.; Mpofu & Chasokela,2025), existing research emphasizes the specific skills and competencies required for effective data utilization and digital transformation within the public sector. For example, Janssen et al. (2020) highlight the importance of data literacy and skills development for public sector employees. Zuiderveen Borgesius et al. (2020) added that, effective data governance frameworks are essential for realizing the benefits of analytics literacy and data-driven innovation. The relationship between analytics literacy and innovation is significantly influenced by digital governance maturity. Mature digital governance, with robust infrastructure, strategic policies, effective leadership, and seamless data integration, amplifies the impact of analytics literacy by providing necessary support systems. This moderating role is supported by existing research emphasizing the importance of organizational context and digital transformation in public sector innovation (Mergel et al., 2019). Leslie et al. (2021) also found the role of data governance in supporting responsible AI implementation and data-driven decision-making within public sector organizations, further underscoring the importance of this moderating factor. Hence, we hypothesize that:

H6: Analytics literacy will significantly influence public sector innovation

H6a: Digital governance maturity will moderate between analytics literacy and public sector innovation

2.7 Public sector innovation on Digital governance performance

Public sector innovation, defined as the development and implementation of new or significantly improved processes, services, policies, organizational structures, or technologies aimed at enhancing public value and addressing societal challenges (Osborne & Brown, 2011). In this study, public sector innovation is operationalized by measuring frequency and impact of new digital initiatives in governance. Public sector innovation is crucial for improved public sector performance and effective governance. This innovation can range from incremental improvements to radical transformations, all aimed at enhancing public value. Public sector innovation plays a pivotal role in shaping digital governance performance by leveraging transformative approaches and technologies to achieve efficiency, transparency, and responsiveness, ultimately improving citizen services and engagement. Extant research underscores the pivotal role of digital transformation in driving public sector innovation and enhancing governance outcomes. Recent studies, for instance, demonstrate the transformative impact of digital technologies and data-driven approaches on public service delivery and governance (Janssen et al., 2020). Moreover, open government data initiatives, a key manifestation of public sector innovation, are recognized for their profound influence on enhancing transparency, accountability, and citizen engagement, which are fundamental tenets of effective digital governance (Zuiderveen Borgesius et al., 2020). Notably, recent research highlights the imperative of robust data governance frameworks for facilitating public sector innovation and effective digital governance (Janssen et al., 2020; Alexopoulos & Janssen, 2020). Thus, the study hypothesizes that:

H7: Public sector innovation will significantly influence digital governance performance.

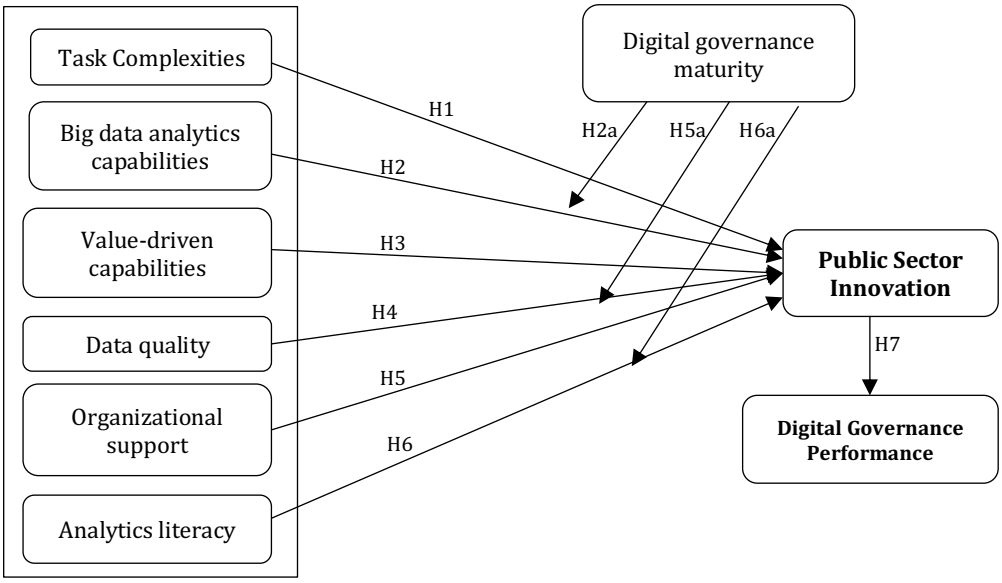

Fig. 1: Conceptual Model of the Research

3. Research Methodology

To adequately measure the determinant of BDA capabilities among public institutions in Ghana, this study employs a quantitative methodology. A questionnaire was developed based on an extensive literature review guided by the conceptual framework in Fig. 1. The first part of the questionnaire gathered demographic information, while the second section posed a series of questions on the determinants of BDA, based on a five-point Likert scale between 1-5 (1=Strongly Disagree - 5=Strongly Agree). To ensure question validity, a pre-test was conducted with sixty (60) respondents, and all questions received favourable results. After the pre-test, participants were purposively sampled using a non-probability sampling approach to ensure that the right respondents were selected from various public institutions in Ghana (Pace, 2021). Participants were selected based on their primary responsibility being data-driven and their appreciable knowledge of data mining. Again, respondents must be innovative-oriented and hold strong opinion about digital transformation. This selection criterion ensured consistency in the responses, justifying the use of purposive sampling aimed at getting results from proactive adopters. Ghana over the past decades have initiated a number of digital initiatives including the open Ghana initiative, national big data initiative, right to information act, and digital acceleration project. Other public sector innovation tools such as e-government system, Ghana digital address systems, e-procurement systems among others, are geared towards streamlining government data collection, processing, sharing and support decision-making across different public sector ministries, agencies and departments. The questionnaire was designed using Google Forms, an online survey tool, and was distributed to participants through a snowballing method between March and October 2024. A total of 310 valid responses were received for analysis.

The Statistical Package for Social Sciences (SPSS) and SmartPLS software were used for the descriptive and partial-

least quare structural modeling (PLS-SEM) analysis respectively. Recent studies have shown that Partial Least Squares Structural Equation Modeling (PLS-SEM) enhances construct variance and endogeneity compared to covariant-based SEM (Egala et al., 2022; Hair et al., 2019). Furthermore, PLS-SEM has been proven to be effective for its predictive relevance capabilities in the model.

The research adhered to all ethical standards, such as confidentiality, informed consent, and disclosing the study's implications to the respondents before answering to the questionnaire. The objective of the study was made clear, and the respondent's private information was kept private. This was done to ensure that all ethical protocols are ensured.

4. Results

4.1 Key findings

As presented in Tab. 1, the respondents comprised 56.5% males and 43.5% females. Majority, 53.9% of the respondents were aged 25 to 40. Relative to the respondent's educational qualification, majority (36.4%), diploma holders followed by bachelor's degree (33.9%) and (28.7%) master's holders. Participants were drawn from departments including Administration (31,6%), budget and planning (25.5%), statistics and IT (20.3%) and finance (19.7%).

Table 1: Demographic Variables of Respondents

Category	Variables	Frequency (N=310)	Percentage (%)
Gender	Male	175	56.5
	Female	135	43.5
Age	18-24	48	15.5
	25-40	167	53.9
	41-60	95	30.6
level of education	Diploma	130	36.4
	Bachelor	105	33.9
	Masters	72	28.7
	Doctorate	3	1.00
Department	Budget and planning	79	25.5
	Procurement	9	2.9
	Administration	98	31.6
	Finance	61	19.7
	Statistics and IT	63	20.3

4.2 Measurement model assessment

As per Hair et al. (2019), it is recommended to have indicator loadings of 0.708 or higher to ensure item reliability. Based on this criterion, variables BC2, OS1 and AL1 were excluded as they did not meet the minimum acceptable threshold. After removing these variables, the data was re-run and the factor loadings resulting from the PLS algorithm are presented in Table 2 and corresponding Fig. 2.

Tab. 2 Construct reliability and factor loadings

Construct/Indicator	Cronbach's Alpha	Composite Reliability	Ave. var. extr. (AVE)	Factor Loadings
PI: *Public Sector innovation*	0.882	0.914	0.679	
PI1: Our organization frequently introduces new digital governance initiatives.				0.809
PI2: We continuously explore innovative ways to improve public service delivery.				0.840
PI3: Our agency encourages experimentation with new digital solutions.				0.812
PI4: We adopt emerging technologies to enhance governance processes.				0.849
PI5: Our organization rewards employees for innovative ideas in digital governance.				0.810
OS*: Organizational Support*	0.856	0.902	0.697	
OS1: Top management actively supports the adoption of BDA.				0.831
OS2: Our agency allocates sufficient resources for digital governance innovation.				0.831
OS3: Employees receive training to enhance digital governance competencies.				0.836

OS4: There is a clear strategy for integrating BDA into governance.				0.839
***AL:** Analytics literacy*	0.839	0.892	0.675	
AL2: Employees in our organization understand how to interpret Big Data insights.				0.842
AL3: Decision-makers use data analytics to guide governance strategies.				0.928
AL4: Our agency has skilled personnel to manage BDA tools.				0.810
***DQ:** Data quality*	0.824	0.876	0.587	
DQ1: The data used in our governance processes are accurate and reliable.				0.748
DQ2: Our agency ensures timely updates of datasets for decision-making.				0.772
DQ3: We have mechanisms to verify the consistency of governance data.				0.757
DQ4: Data privacy and security measures are strictly enforced.				0.767
DQ5: Our Big Data sources are relevant to public sector needs.				0.780
***DP:** Digital governance performance*	0.866	0.903	0.651	
DP1: Digital governance tools improve service delivery efficiency.				0.806
DP2: Citizens are more satisfied with our digital public services.				0.846
DP3: Our agency reduces operational costs through digital governance.				0.805
DP4: Decision-making processes are faster due to data-driven insights.				0.826
DP5: Transparency and accountability in governance have increased.				0.745
***VC:** Value- driven capabilities*	0.819	0.873	0.579	
VC1: Our organization prioritizes citizen-centric values in digital governance.				0.759
VC2: Ethical considerations guide our use of BD in public services.				0.798
VC3: We align digital governance strategies with societal needs.				0.745
VC4: Stakeholder feedback is incorporated into governance innovations.				0.718
VC5: Our agency balances efficiency with equity in digital service delivery.				0.779
***BC:** Big Data Analytics capabilities*	0.767	0.848	0.584	
BC1: Our organization has the infrastructure to process large datasets.				0.792
BC3: We use predictive analytics to improve governance decisions.				0.700
BC4: Real-time data analytics enhance our responsiveness to public needs.				0.819
BC5: Advanced analytics tools (AI, machine learning) are leveraged in governance.				0.738
***TC:** Task Complexities*	0.825	0.876	0.586	
TC1: The governance challenges we face require sophisticated data analysis.				0.706
TC2: Multiple stakeholders increase the complexity of decision-making.				0.778
TC3: Regulatory constraints complicate digital governance implementation.				0.816
TC4: Rapid technological changes demand continuous adaptation.				0.805
TC5: Data integration from diverse sources is a challenge for our agency.				0.714

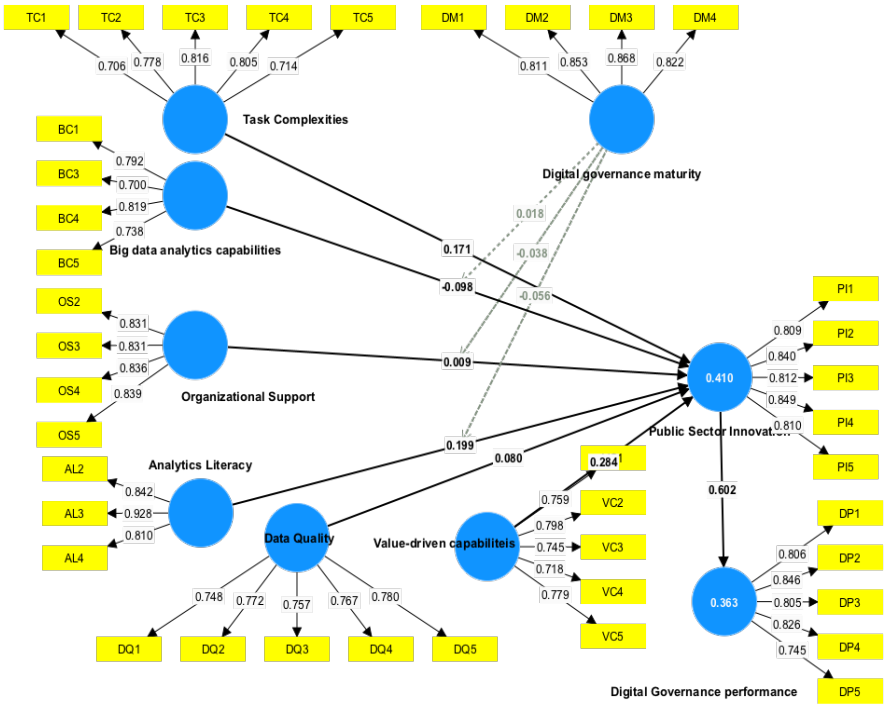

Fig. 2: Factor loadings

To ascertain the reliability of the constructs, Hair et al. (2019) recommend that composite reliability (CR) values between 0.60 and 0.70 are acceptable, 0.70 and 0.90 are good and values exceeding 0.95 are problematic since they cause a decline in the reliability of the model (Henseler et al., 2009). As shown in Tab. 2 all CR values were within the threshold indicating good reliability among constructs. The Average Variance Extracted (AVE) was also used to measure the convergent validity (CV) across all the items specific measured construct. CV is the degree to which separate items reflecting a concept converge or meet when compared to items measuring a distinct construct (Hair et al., 2019). The AVE's cut-off value is 0.50, which indicates that 50% of the construct's explanation of item variability is acceptable for CV (Hair et al., 2019). The AVE values derived for this study were above the 0.50 threshold indicating a satisfactory convergent validity.

Relative to the discriminant validity, the study adopts the Heterotrait-Monotrait ratio (HTMT) criterion given the weaknesses in the Fornell-Larcker criterion (Henseler et al., 2015), for its ineffectiveness in accounting for the uniqueness between the indicators. Tab. 3 presents the HTMT values between constructs which was within the acceptable range. The study adopts Henseler et al. (2015) recommended 0.85 threshold which suggest that, construct with this threshold are conceptually distinct.

Tab. 3 Discriminant validity with Heterotrait-Monotrait Ratio (HTMT)

Construct	1	2	3	4	5	6	7
BDA Capabilities							
Organizational support	0.479						
Analytics Literacy	0.281	0.15					
Data quality	0.576	0.753	0.098				
Digital governance performance	0.690	0.357	0.180	0.459			
Value- driven capabilities	0.606	0.589	0.096	0.829	0.591		
Big data analytics capabilities	0.486	0.497	0.192	0.762	0.340	0.812	
Task complexities	0.495	0.450	0.180	0.646	0.284	0.677	0.931

4.3 Structural model assessment

The next step was to access the inner structure of the model to determine the presence of collinearity with the predictor variables. When two or more formative indicators with the same values are inserted in the same block of indicators, collinearity occurs (Sarstedt et al., 2020). High degrees of collinearity impact on the formative indicator's statistical significance and weight estimate. It is thus, recommended that, the variance inflation factor (VIF) is kept low not above 5 (Hair et al., 2012). In this study, no collinearity problem existed since all VIF values.

The study finally tested the relationship among constructs using the PLS-SEM bootstrapping algorithm. This study

used the *t-statistic* values to measure the effect of the independent and mediating variables on the dependent variable relying on the recommended 1.65 threshold based on the 95% confidence interval (Hair et al., 2019). From the Ta. 4, six hypotheses (*H1, H3, H4, H5, H6 and H7*) out of the seven were supported.

Tab. 4 PLS-SEM Path Coefficients and hypotheses

	Hypothesis Relationship	**Std Beta**	**Std Error**	**T_Stat.**	**Interpretation**
H1	Task complexities -> Public sector innovation	0.205	0.126	1.693**	Supported
H2	Big data analytics capabilities -> Public sector innovation	-0.042	0.101	0.557	Not supported
H3	Value-driven capabilities -> Public sector innovation	0.28	0.083	3.415**	Supported
H4	Data quality -> Public sector innovation	0.123	0.07	1.732**	Supported
H5	Organizational support -> Public sector innovation	0.125	0.07	1.721**	Supported
H6	Analytics literacy -> Public sector innovation	0.214	0.046	4.664**	Supported
H7	Public sector innovation -> Digital governance performance	0.607	0.064	9.393**	Supported
Variables		*Coefficient of determination (R^2)*			*Adjusted R^2*
Public sector innovation		0.382			0.369
Digital governance performance		0.367			0.365

*Note: t denotes two-tailed statistics at **05 significant level*

To demonstrate the predictive capability of the model, an assessment of the structural model's path coefficient significance was performed to determine the goodness of fit (GOF) (Jung & Park, 2018). The commonly used criterion for this purpose is the determination coefficient (R^2), which gauges the exploratory power of the model (Hair et al., 2019). The range of R^2 values is from 0 to 1, with higher values indicating a greater level of explanatory power. R^2 values of 0.25, 0.50, and 0.75 are typically considered to be weak, moderate, and substantial, respectively (Hair et al., 2019). As shown in Table 3, the R^2 values were above 0.30, indicating a substantial model fit.

4.4 Moderation analysis

A moderation analysis was conducted to determine the moderating effect of digital governance maturity on the connection between the big data analytics capability, organizational support and analytics literacy, and public sector innovation. This was to find out how digital governance maturity affect the attainment public sector innovation. Using the t-value of 1.65 (Hair et al., 2019) as the benchmark, the result is shown in Tab. 5.

Tab. 5. Moderating Analysis result

Relationship	**Original Sample (O)**	**t- values**	**P Values**
IT*CO -> BDA	-0.048	0.595	0.552
IT*DS -> BDA	-0.08	1.135	0.257
IT*TI -> BDA	0.036	0.435	0.663

5. Discussion and implications

The results revealed that task complexity, value-driven capabilities, data quality, organizational support, and analytics literacy are the key factors influencing public sector innovations within the Ghanaian public sector. This finding aligns with prior research, including studies by (Egala & Afful-Dadzie, 2022; Yusif, 2017), which highlight the growing recognition of BDA capabilities as pivotal in enhancing decision-making, improving operational efficiency, and optimizing service delivery in public sector organizations.

The study identified that public sector innovation is significantly influenced by task complexity, value-driven capabilities, data quality, organizational support, and analytics literacy, validating hypotheses H1, H3, H4, H5 and H6. Instructively, H7 was also supported validating the proposition that, while the later antecedents lead to innovations in the public sector, it has a significant impact the performance of digital governance. These findings align with prior research by Joshi et al. (2021) and Didas (2023), which similarly highlighted these factors as key determinants of BDA adoption. Furthermore, Waqar and Paracha (2024) submit that BDA serve as a crucial enabler, offering public sector organizations the ability to strategically leverage data resources to enhance both academic and administrative task quality. Given these insights, it is recommended to increase investments in data analytics and business intelligence tools to strengthen decision-making processes. Additionally, this study underscores the importance of advancing the value of BDA to enhance decision-making and comprehensively assess the adoption and performance of digital governance in Ghana's public sector.

The findings indicate a significant relationship between value-driven capabilities (H3), data quality (H4), organizational support (H5), and analytics literacy (H6) in the context of technology characteristics. This suggests that public sector innovation's ability to provide organizational support, foster analytics literacy, improve data quality, and facilitate value-driven capabilities plays a critical role in determining the extent to which organizations adopt and effectively utilize such innovations (Lee et al., 2024).

In line with the guided theory, Larosiliere and Carter (2016), note that, the integration of ICTs within organizations significantly influences task operations. The study emphasize that the technological aspects of a task enable individuals within an organization to interact, collaborate, and participate more effectively in organizational activities. These insights highlight the importance of aligning technological characteristics with organizational needs to maximize the impact of public sector innovation (Arunde et al., 2019).

The findings of this study highlight that public sector innovation provides institutions with an efficient and effective platform for mining and utilizing data to enhance performance. Additionally, the technological characteristics of such innovations support seamless data access for users and allow for customization to achieve desired outcomes. Yoo and Kim (2019) observed that technology adoption increases when the alignment between the nature of the work and the technology is strong. Furthermore, the collection, storage, and utilization of big data require significant attention, emphasizing analytics literacy as a critical component of public sector innovation (Saggi & Jain, 2018). Supporting this, Solangi et al. (2018) identified data analytics literacy as one of the most crucial issues concerning data utilization. The study also underscores the importance of data security, revealing its significant influence on the successful adoption and implementation of public sector innovation.

However, the study revealed that BDA capability was not the most suitable fit for public sector innovation in Ghana. This finding contrasts with the conclusions of Brock and Khan (2017), who emphasized that BDA capabilities play a crucial role in facilitating the implementation of technology. This contradiction suggests that the effectiveness of BDA capabilities may vary depending on contextual factors, such as the specific technological, organizational, and environmental conditions within a region or sector.

The study found that digital governance maturity had no moderating effect on organizational support, analytics literacy, and Big Data Analytics (BDA) capabilities concerning the utilization of public sector innovation. This finding contradicts previous research, such as Wu et al. (2019), which highlighted that IT architecture appropriateness significantly influences the adoption and viability of IT implementation in organizations. Wu et al. (2019) argued that the alignment of IT architecture facilitates smoother technology adoption, leading to enhanced organizational efficiency. Similarly, Chege et al. (2020) emphasized that a well-structured IT architecture supports the integration of new technologies, improving operational efficiency. Tam and Oliveira (2016) further established that technology infrastructure has a substantial impact on task performance. Despite these contradictions, the study acknowledges the ongoing concerns surrounding analytics literacy in the context of data privacy and security. As Siddiqa et al. (2016) highlighted, safeguarding data integrity through secure computational tools and effective distributed storage systems is a critical element of public sector innovation. While this study's findings suggest that public sector innovation and organizational support require minimal reliance on digital governance maturity for performance enhancement, it reinforces the importance of preserving institutional data integrity as a foundational aspect of innovation. Robust data security measures remain essential to ensure the successful adoption and utilization of public sector innovation.

Empirically, this study provides valuable insight into how task-technology and value-driven characteristics influence the implementation of public sector innovation and their consequences on digital governance performance. Drawing on Przegalinska et al. (2025) introduction of task complexities and big data analytics capabilities, we extend the TTF framework to account for the evolving nature of BDA within public institutions. Notably, this research is among the first to examine public sector innovation from a developing country's perspective, addressing a gap in existing literature that has largely focused on developed contexts. In Ghana, for instance, organizations face unique challenges in acquiring both the technical and human resources essential for successful innovation.

To bridge this gap, we synthesize factors such as big data analytics and value-driven capabilities, analytical literacy and digital governance maturity and into the TTF model, recognizing that public sector innovation hinges not only on technological considerations but also on business processes and value propositions. While previous studies have predominantly emphasized technical variables, this work responds to calls for a deeper investigation into the "dependent side" of the TTF model namely, productivity and performance, which our findings affirm as key outcomes of innovation adoption. Although our moderating analyses did not yield significant results, the importance of providing robust IT infrastructure remains evident.

This study also underscores that simply investing in public sector innovation does not automatically lead to positive outcomes. For employees with non-routine tasks, selecting the right ICTs can indeed boost productivity, but achieving the desired impact requires more than just equipment provision. Organizations must also align users'

culture and work practices with their core business processes to fully capitalize on these investments.

Moreover, public sector innovation initiatives should be adaptable to the specific activities and organizational practices of the public sector and other public entities. Overreliance on ICT tools without considering tasks, hierarchies, and decision-making processes can diminish potential value. Consequently, a supportive policy environment that encourages staff and other stakeholders to embrace and effectively use public sector innovation is crucial. This includes granting staff appropriate access to IT infrastructure for collaborative work and instituting ICT policies (e.g., database use policy, internet use policy) to safeguard user information. Lastly, government-led educational and ICT policies can further ensure the protection and security of information, thus fostering a more conducive environment for public sector innovation.

6. Conclusions and limitations

The objectives of the study were to examine the nature of BDA, investigate the factors that influence BDA fit in task-oriented activities, and assess the impact of BDA on Public sector in Ghana. Drawing on the TTF, the study employs and exploratory approach and collected data from 310 public sectors workers in Ghana. The study uses PLS-SEM analysis to analyse the data. The findings revealed that innovations in the public sector are driven by factors such as task complexity, value-driven capabilities, data quality, organizational support, and analytics literacy as key antecedents of BDA use in public sector of Ghana. Unfortunately, the proposition that, big data analytics capabilities influence public sector innovations was not support. The study also found that, public sector innovations through BDA contribute significantly to their digital governance performance in Ghana. The study presents several implications for theory and practice as technology keeps changing the public sectors landscape in Ghana yet, fraught with several challenges in its adoption, use and implementation.

The research was limited by the context in which it was studied and the adopted methodology. While this presents a practical case for a developing economy, future research can leverage other methodologies to explore other geographical context for a broader understanding of the digital governance and how BDA transforms public governance. Again, a comparative analysis could also enhance the generalizability of the future studies. Theoretically, other theories may also be leveraged to explore similar phenomenon.

Using ICT to Patch the Shortcomings of New Public Management in a Post-Communist Welfare State

Sebastian Sosnowski [a*]

[a] Graduate School for Social Research & Institute of Philosophy and Sociology, Polish Academy of Science Warsaw, Poland, sebastian.sosnowski@ifispan.edu.pl, ORCID number: 0000-0002-2436-0022

Submitted: 31 January 2025, Revised: 26 March 2025, Accepted: 21 April 2025, Published: 30 June 2025

Abstract. New Public Management approach in the welfare sector led to outsourcing and disaggregation of the services, which makes it difficult to implement new ICT technologies into such context. In this paper, I analyse the case of Electronic Care System (ECS) implemented in selected municipalities in Poland. These municipalities carry different characteristics of inhabitants and service provision. Additionally, Polish welfare system is a case of transformative system which is a mix of diverse European systems. I analyse secondary data (documents, strategies), interviews and observations regarding the implementation of ECS. Based on that, I draw the main conclusions regarding how context of welfare provision impedes the successful implementation of the ICT within the public institutions. I argue that introduction of ICT in fragmented institutions needs to include diverse perspectives of stakeholders and take into account the values important for the system users. Especially, I focus on how diverse modes of care provision need to be mirrored in the systems, how political and managerial pressures make it more difficult for other actors to navigate through the change. At the end, I ask the question about organisational and cognitive costs of implementing innovations.

Research paper, DOI: https://doi.org/10.59490/dgo.2025.1062

1. Introduction

Currently, new technologies are increasingly being introduced into the sphere of social support and welfare policies (Alston, 2019). They are designed to improve administrative efficiency and facilitate the functioning of citizens-beneficiaries, among other things, through automated decision-making (ADM). However, the implementation of such solutions is highly dependent on the context in which a given institution operates (Broomfield & Reutter, 2022), including the approach of the involved stakeholders. In this paper, I analyse the case of the Electronic Care System (ECS) introduced in selected Polish municipalities to support the process of granting and providing care services for the elderly and people with disabilities. I argue that ECS, functioning in the context of Poland's mixed welfare state model, exemplifies thinking described as **post-New Public Management** (NPM), in which the state institutions try to regain control over the privatised elements of public services (e.g. Howard, 2015; Anttiroiko & Valkama, 2016), and I will outline post-NPM features of the researched system. In doing so, I pay attention to context-specificity of the researched case.

The importance of welfare and social security is mirrored in the content of recent EU strategies and budgetary plans (Frączkiewicz-Wronka et al., 2024). European welfare state models are the subject of analysis and categorization, though these studies are largely focused on Western Europe (e.g. Esping-Andersen, 1990; Titmuss & Abel-Smith, 1990). With the ongoing digitization of various aspects of Europeans' lives, welfare states are also integrating new technologies into their daily operations. The so-called **"digital welfare state"** (Dencik, 2022) has become an increasingly discussed subject of research (e.g. O'Neil, 2016; Eubanks, 2017; Gantchev, 2019), particularly due to its direct impact on citizens' well-being. However, there is scarce literature connecting implementation of new technologies with wider context of welfare institutions, including research on countries of

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

Central and Eastern Europe, which was called by Esping-Andersen "the most under-defined region, a virtual laboratory of experimentation" (Esping-Andersen, 1996, p. 267).

This article aims to fill this gap by describing the case of digitalisation in care services through the ECS in selected Polish municipalities and introducing it in the context of welfare assistance. Poland is an example of a post-communist country where state institutions (including welfare assistance) and society are undergoing a transformation from a centrally planned economy with a strong bureaucratic presence to a market economy in which state administration plays a less dominant role (Golinowska, 2009b; Księżopolski, 2013). I aim to answer the following research questions: 1) What are **the goals delineated by policy-makers** for the ECS and **how do they relate to the idea of NPM**? 2) What is the **role of new technologies** in this case, considering the concept of **New Public Analytics** (NPA; Yeung, 2023)? The presented case study is a part of broader project AUTO-WELF: Automating Welfare – Algorithmic Infrastructures for Human Flourishing in Europe.

The paper is structured as follows. First, I describe the organisation of welfare assistance system in Poland with special attention to current social problem – ageing population. Consequently, I introduce the concepts of New Public Management, post-New Public Management and New Public Analytics that will be a theoretical framework for the analysis. Next, I present the methods of the research and analysis of the data. After that, I describe the main findings from the analysis divided into three main categories: diverse mode of service provision, managerial pressure for innovation and costs of innovation spread among stakeholders. I sum up with remark that implementation of new technologies in the welfare service need a close and thorough analysis of possible future scenarios from different perspectives of involved actors.

1.1 Organisation of Welfare Services in Poland

Social security system in Poland is divided into several pillars, which include health insurance, employment agencies, social insurance and welfare assistance (social services and benefits, mostly directed to families) (Rusiecka, 2023). In this paper, I will focus on the last element of the system, which is also responsible for provision of care services.

As a unitary state with three-level system of administrative division, the control over the welfare assistance and services in Poland is mainly in the Ministry of Family, Labour and Social Policy (MRPiPS). However, the greatest responsibilities to provide social assistance to citizens is in the smallest administrative units – gminas (communes, municipalities). The social assistance system provides support in form of financial or material benefits and services, such as legal and psychological support, social work or care provision for the elderly. Each gmina has a Social Welfare Centre (SWC) that is obliged to provide direct support to gmina's inhabitants in order to fulfil their basic needs (Ministry of Family, Labour and Social Policy, 2019; Dz.U. 2004 Nr 64 Poz. 593, 2004). As a result, gminas define their own strategies and plans for the development of social policy, which is largely decentralized but operates within a uniform legal and institutional framework. Recently, big social programmes were introduced (e.g. 500+ benefit for families with children, "Active Parent" programme for employed parents), which are an example of central social policies. However, the responsibility for such programmes is laid on central Social Insurance Institution (ZUS) rather than on local SWCs.

In the wake of the departure from communism and the systemic transformation of the 1990s, the main focus was on labour market issues and social assistance (Golinowska et al., 2009). The "shock therapy" proposed by Leszek Balcerowicz also involved a significant reduction in funding for social support (Księżopolski, 2011) and such a rapid and dynamic transition to a free-market economy was unprecedented in Europe, carrying high social costs. Marketisation of the economy produced "winners" and "losers" of economic transformation (Debicki & Debicka, 2008) and led to deepening social inequalities (Księżopolski, 2011).

Due to the ambitions of the ruling elites to integrate Poland into the structures of the European Union, social policy goals were largely subordinated to economic development, including activation policies, the flexibilization of employment forms at the expense of workers' rights (Golinowska, 2018), as well as low amounts of social benefits (Księżopolski, 2013). These changes were facilitated by prevailing public sentiments, which embraced the liberal rhetoric of the need for low taxes and a reduction in state interventionism (Rae & Piotrowska, 2022) and insufficient spendings in this domain.

The main focus of social assistance in Poland is on family rather than on individuals. This is also expressed in "familisation" (Esping-Andersen, 2003) of the support system: the relatives have the primal responsibility to support family members and in case of its insufficiency or denial, institutions provide support. Some of the services are subsidiary, meaning that they are partially paid, based on the material situation of the beneficiaries and their families. The welfare state model in Poland is described as "mixed" (Siemieńska & Domaradzka, 2016) between conservative and liberal models. The former is because of great significance of the family obligations within the system. The latter is due to strong orientation of some of the institutions towards employment activisation and to using market mechanisms, such as outsourcing, when institutions are unable to provide services. Moreover, during

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

the transformation period, the existing social infrastructure was often privatised due to lack of resources (Siemieńska & Domaradzka, 2020).

Mirosław Księżopolski describes **Poland's welfare state model as a "paternalistic-market hybrid"** (2011, p. 16), which combines elements of state-guaranteed social security with capitalist economic principles, rarely constrained by the state. Private entities have been incorporated into the provision of certain services—such as healthcare, elderly care, and education—to compensate for the shortcomings of the state. The word "paternalistic" denotes not only the degree of state interventions, but also specific mindset about passive citizens: "*The modern Polish state is still largely perceived as an external entity that acts ‹*instead of*› citizens rather than as a service-oriented institution that acts ‹*for*› them*" (Księżopolski, 2011, p. 32). Additionally, this system remains inconsistent, leading to mixed public perceptions (Rae & Piotrowska, 2022). Despite dynamic economic growth, particularly after Poland's accession to the European Union, no significant reforms or increased investments in social assistance followed. Instead, the welfare system remains closely tied to the dominant capitalist economy, with citizens' livelihood largely dependent on their position in the labour market (Księżopolski, 2013). Even the introduction of big social programmes as 500+ (later increased to 800 PLN per month) and "Active Parent" are examples of direct cash benefits respectively to families or to private entities, which limits the role of the state in the family policy and service provision (Siemieńska & Domaradzka, 2020). Additionally, the latter is an example of strong connection between social policy and employment goals.

One of the biggest challenges for European welfare states (Anttiroiko & Valkama, 2016; European Commission. Statistical Office of the European Union., 2020), including the Polish welfare system (Golinowska, 2009a; Księżopolski, 2011; Siemieńska & Domaradzka, 2016) is **ageing population**. This is a result of decrease in both fertility and mortality, as well as increasing life expectancy of European societies. In 2023, the Polish society consisted of **more than one quarter of people aged at least 60 years old**[1]. The senior population is relatively young, with the most numerous group aged between 65 and 69 years old (app. 25% of seniors). Almost two thirds of seniors live in cities or towns. The average life expectancy for males is 75 years, whereas for females – 82 years. In household consisting of solely older persons, the most frequent basic source of income are social benefits, with the highest share coming from retirement pay and pensions. However, 5,7% of households in which lived older person reported rather bad or bad material situation (Wyszkowska et al., 2024). Considering projected decreasing population in the working age (Stachura & Strzelecki, 2023), **one of the challenges in the future would be to provide care and fulfil basic needs of dependent elderly**.

1.2 From New Public Management (NPM) to New Public Analytics (NPA)?

The beginning of changes in public institutions that indicated the adoption of **New Public Management (NPM)** thinking can be traced back to the 1980s, particularly in countries of the so-called Global North, where political leaders came to power advocating reforms. These leaders promoted the need for changes inspired by neoliberal and free-market principles, aiming to reshape the functioning of public institutions that had been weakened by the financial crisis of the 1970s. As a result, public institutions adopted a more managerial approach, characterized by cost-cutting measures in public services, primarily through outsourcing to non-governmental sector entities (Hood, 1991).

NPM has manifested in several political decisions that were aimed at mimicking the managerial style of private entities in public sector, which included marketisation of the services. The hidden underpinning of these reforms was the belief that competition among several service provider would lead to lower prices and increased service quality. In many instances, NPM also brought decentralisation of the existing institutions and introduction of mostly quantitative-based performance measurements and auditing. Inefficient institutions faced budget cuts or top-down pressure to improve the performance (Gruening, 2001). Noteworthy, the implementation of NPM principles was perceived as non-political (Yeung, 2023), allegedly separating politics and administration. However, as presented by Samier, efficiency, effectiveness and focus on economic performance were the organising ideas for NPM institutions (Samier, 2005).

In Central and Eastern European (CEE) countries, **the principles of NPM were adopted during the systemic transformation of the 1990s**. This was largely due to the widespread popularity of this approach in the public administration of Western European countries, and most notably, in the United States. Post-communist states, which lacked sufficient experience and knowledge regarding the functioning of NPM, were more likely to adopt this model rather than the social-democratic approach used in neighbouring Scandinavian countries. This choice was also influenced by international financial institutions, particularly the International Monetary Fund (IMF) and the World Bank. These institutions demanded rapid reforms, primarily aimed at reducing public spending, as a prerequisite for debt negotiations and development aid (Randma-Liiv, n.d.; Randma-Liiv & Drechsler, 2017). This context lead to adaptation of **cost-effectiveness accountability** rather than accountability for the social outcomes

[1] The retirement age in Poland is 60 years for women and 65 for men.

Copyright ©2025 by the authors. This conference paper is published under a CC-BY-4.0 license

of the reforms (Parker & Gould, 1999).

Empirical research on NPM reforms has identified key problems with this approach. Reliance on the market and outsourcing of services caused **control and accountability deficits** in public administration. Fragmentation of institutions and, in some cases, agencification **hampered managerial responsibilities** of public servants and could have the effect on delivery of **disjointed and inconsistent services** to citizens (Howard, 2015). In the context of CEE, especially Poland and Hungary, there is no strong civil service, which leads to **politicization of administration** and hampers its development (Randma-Liiv & Drechsler, 2017). Fragmentation of the institutions results in diverse dynamics of development. Also, as shown during the COVID-19 pandemic, institutions are forced to response to crisis situation without much prior preparedness (Sosnowski et al., 2021). However, implementation of NPM had positive impact by providing ideas for modern administration and highlighting the importance of administration reforms (Dan & Pollitt, 2015; Debicki & Debicka, 2008).

Public administration has sought to adapt to identified issues through a process of service reintegration and coordination. Changes NPM were also influenced by negative assessments of its effectiveness, the erosion of political control, and a growing sense of insecurity in the modern world. Christensen and Lægreid refer to this trend as the "rediscovery of bureaucracy" (Christensen & Lægreid, 2011, p. 141) or **post-New Public Management** (post-NPM; 2011, p. 132), though it has led to the emergence of complex and hybrid organizational forms. The authors argue that linear or cyclical perspectives on administrative development should be rejected. This shift is particularly driven by the fragmentation of public administration, where different institutions implement changes independently, at their own pace and according to their own priorities. Additionally, the expectations of service users are changing, especially regarding its quality. Nonetheless, the demographic changes and curbing public spendings are the reason that bureaucracies seek to improve performance in order to assure quality increase (Kinder, 2012).

Karen Yeung (2023) introduced the term **New Public Analytics (NPA)** to denote new approach in public administration in the age of digital transformation. NPA manifests in reliance on datafication and automated decision-making, which is supposed to make governance seamless. Disregarding varying degree of sophistication of ICT solutions, NPA approach offers improvement in procedures rather than ideological change in the functioning of administration. ICT is therefore treated as a tool to achieve better measurable outcomes than new paradigm. Yeung highlights the continuity between NPM and NPA, especially in orientation towards market solutions and reliance on evidence-based policy making, allegedly neutral in political implications (Kempeneer, 2023).

However, NPA is built on ideological foundations, which Yeung describes as **"neoliberalism with a techno-solutionist makeover"** (Yeung, 2023, p. 16). Just like NPM, NPA is market-driven and oriented toward competition. Solutions implemented in social policy and welfare often adopt market-based solutions, which are rarely adjusted to the specific organizational context (e.g. O'Neil, 2016). Social problems are perceived as opportunities for technological innovation, but the primary goal remains profit generation. Nevertheless, Shirley Kempeneer argues that the cause of the problem in possible algorithmic injustices is not a new paradigm, rather it is deeply rooted in NPM logic of disaggregation, competition and incentivisation for improvements (Kempeneer, 2023).

In case of Polish welfare assistance, the institutions seem stable. Since the local self-government reform in 1990, the smallest administrational units (gminas) are responsible for the implementation and provision of social assistance to their inhabitants through Social Welfare Centres using material benefits and services. Despite the definition of eligibility criteria for support are defined in the Social Assistance Act from 2004, social workers have discretionary power, e.g. by withholding documentation or "creaming" clients, meaning serving mostly a promising group of individuals (Sosnowski et al., 2021; Trochymiak, 2018). In 2019, the Act on Provision of Social Services by Social Services Centres has created a possibility for local authorities to introduce such Centres (SSC). The aim of this change was to integrate and coordinate fragmentised net of services and dividing social assistance from social services (Szarfenberg, 2021). This aligns with the logic of both NPM (decentralisation and discretionary to manage) and post-NPM (attempt to reintegrate institutions and creating hybrid and complex organisations).

From almost 2500 gminas in Poland, all of them vary in terms of their economic and political development, disfavouring less economically developed ones to develop administrational structures and implement innovations (Debicki & Debicka, 2008). Stanisława Golinowska points out that NPM was largely accepted in Polish administration, mostly because of replacing the burden of service provision and, in some cases, of guaranteeing its good quality (Golinowska, 2018). Parallelly, the decreasing quality of public services created a demand for privately provided ones, especially in education, health and long-term care. Even if private suppliers are subsided by the authorities, the possibility to control the service is limited. As stated by Golinowska:

> *"The functioning of social services, a fundamental pillar of the welfare state, in Poland is **varied and chaotic, with unequal access** contributing to social disparities. However, the general belief among Polish society persists—that access to these services can somehow be ‹arranged›, either through informal means or by having the necessary*

funds to pay for them. As a result, individuals facing higher risks (e.g., people with disabilities) tend to demand direct ‹cash› rather than services, such as rehabilitation, caregiving, or specialized equipment." (Golinowska, 2018, p. 127-128)

The digitization of public services in Poland is also fragmented, primarily due to the decentralization of institutions. Aside from the existing ministerial statistical system, SWCs use various solutions, all of which must receive ministerial certification (Frączkiewicz-Wronka et al., 2024). The Social Assistance Act specifies, among other things, the scenario for standardised community interviews (pl. *wywiad środowiskowy*), but it does not define whether they should be conducted using new technologies or simply written on paper. In some SWCs, a dual document circulation system is in place: paper-based personal files are maintained for beneficiaries, while at the same time, these documents are scanned and stored digitally.

1.3 Electronic Care System (ECS)

The ECS is one of the examples of using new technologies in welfare assistance in Poland. It is introduced in almost over 20 gminas that are geographically neighbouring, nevertheless caring different characteristics of inhabitants. Almost two thirds of them have big city characteristics (hereinafter: urban gminas). The rest is rural or small-town (hereinafter: rural gminas). Due to involvement of numerous administrative units, the case involves complex network of public organisations (including SWCs and SSCs and municipal authorities) and private companies (responsible for provision of care services and IT infrastructure and software).

Care services for partly independent citizens are provided in-house to help them accomplish daily routines. As described above, the primary obligation to support the elderly is on family members, however in case of their lack of resources, social workers from SWCs may decide to allocate care services also to persons living with their families. The financial aspect of the service depends on the gmina's regulations. If family has sufficient incomes, beneficiaries are obliged to financially contribute to the service. SWC has a discretion to exempt beneficiary from the payment in case of documented circumstances.

The process of granting the service begins with an application from the possible beneficiary, their family members or persons from community. After that, social worker from SWC is obliged to conduct community interview with either the applicant or other household members. During the interview, a lot of personal information, including financial status, health condition or existing relationships, are collected. Based on the information from the interview, social worker issues an administrative decision, which needs approval from the SWC director. The decision includes the information about care services scope, meaning performed tasks and number of hours prescribed to the beneficiary.

The ECS consists of a few components. Social workers responsible for conducting community interviews use Digital Interview app to record them on laptops. Caregivers, employed either by private companies (mostly in urban gminas) or by SWCs, use mobile app of ECS (hereinafter: mobile ECS) to access the information about beneficiaries and assigned tasks to perform during work hours. Mobile app also uses near-field communication (NFC) for caregivers clock-in and clock-out from their beneficiaries apartments. The managers in the SWCs, SCCs and private care companies use software allowing them to create timetables, control the punctuality of the service (based on NFC log-ins) and exchange documentation, including fiscal documents.

The additional features of the system is the profiling algorithm and remote care component. The former is designed based on a data collected in additional questionnaire during the community interview. The algorithm takes into account physical and "mental" autonomy of the service beneficiary and based on assessment allocates them in one of nine profiles of autonomy. Based on this assessment, the software suggests social workers the possible scope of prescribed care services (in weekly hours of the service).

The remote care uses indicators either installed in the apartments of beneficiaries or wearable technologies. The component includes wristbands monitoring the life functions and equipped in emergency button. Wristbands can also detect if the person has fallen down and connect the beneficiary with monitoring centre, which can further call the emergency services. The other technologies used in the remote care are detectors of smoke and carbon oxide, as some of the houses in rural gminas use heating stoves. One of the element are also key boxes used by caregivers and emergency services.

2. Research methods

In this research, we implemented case study approach combining several research methods, including secondary data analysis (existing documentation, policy strategies etc.), in-depth interviews and organisational ethnographic observations. These activities were taken by two team members, including the author. The research received

approval from the Research Ethics Committee of the Institute of Philosophy and Sociology of the Polish Academy of Sciences.

As the researched system is an example of public-private partnership, there is a rich documentation of the procurement procedures, design plans and descriptions of the ECS. Also, we paid attention to municipalities' policy documents, especially regarding welfare assistance and their development strategies. This stage helped us to better understand local specificity of the policy area and map the possible interviewees for the further stage of the research.

We conducted several interviews with various stakeholders involved in the process of design and implementation of the system. Among our interviewees are management-level employees of municipalities' offices, employees of private companies, namely IT company commissioned to develop the software and companies providing care services in numerous of researched municipalities, and employees of the social assistance institutions (SWCs and SCCs).

Additionally, we participated in the testing meetings of workers of SCCs and private care companies, which happened in the care services beneficiaries' places of residence. These testing meetings were mostly focused on teaching caregivers how to log in to the mobile app and to use the NFC technology within the app. From these meetings, we collected fieldnotes based on the observations of researchers (Emerson et al., 2011).

Audio recordings of the interviews were transcribed and anonymised. All collected data – documents, fieldnotes, interview transcriptions – were uploaded in the shared workspace in Qualitative Data Analysis (QDA) software. For data analysis, we used a standardised coding system, which was developed and discussed with the team. We also used memos to describe analysis insights.

Case study research are perceived as valuable in the context-dependent environments (Flyvbjerg, 2006), especially when using several research methods and data sources. In this paper, I use case study to "elicit the strategic structure of an event" (Widner et al., 2022, p. 8), namely to describe interactions leading to deployment of ICT systems in the welfare assistance area in "paternalistic-market hybrid" (Księżopolski, 2011, p. 16).
